HENRY, surnamed THE NAVIGATOR, a famous Portuguese prince, the fourth son of John I, king of Portugal, was born at Oporto in 1394, and first distinguished himself at the conquest of Ceuta in 1415. After the death of his father, he took up his residence at the town of Sagres, in Algarve, not far from Cape St Vincent; and while prosecuting the war against the Moors of Africa, his sailors reached parts of the ocean which the navigation of the time had long supposed to be inaccessible. The grand ambition of H. was the discovery of unknown regions of the world. At Sagres he erected an observatory, to which he attached a school for the instruction of youthful accons of the nobility in the sciences necessary to navigation. Subsequently, he despatched some of his pupils on voyages of discovery, which resulted at last in the discovery of the Madeira Islands in 1418. H.'s thoughts were now directed towards the auriferous coasts of Guinea, of which he had heard from the Moors; and in 1420, one of his mariners sailed round Cape Nun, until then regarded as the furtthest point of the earth, and took possession of the coast as far south as Cape Bojador. The next year, H. sent out a larger ship, with several points 130 miles beyond Cape Bojador; and at last, in 1440, Cape Blanco was reached. Up to this period, H. had borne all the expense of these voyages himself, and the increased number of his mariners was due to his personal influence and what had formerly been the affair of a single individual, now became the passion of a whole nation. But H. did not slack personally in his efforts. In 1446, his captain, Nuno Tristan, double Cape Verd in Senegambia, and in 1448, Gonzalez Vallo discovered three of the Azores. H. died in 1463, after he had the satisfaction of learning that his mariners had reached as far south as Sierra Leone. See Wappius, Unteruchungen über die Großen Entdeckunger der Portugiesen unter H. dem Seefahrer (Göt. 1842). See also Barros and Candido Luisino, whose Vida do Infante don Henrique was translated into French by the Abbé Courmand (Paris, 2 vols. 1781).

HENRY, surnamed THE LION, Duke of Saxony, is the most notable German prince of the 12th century. He was the son of Henry the Proud, and was born in 1129. When only ten years of age, he lost his father by poison, and for the next seven years, he lived with his wife, Gertrude, and his grandson, Richard, under his paternal dominions, while his uncle, Welf (Guelf), administered the hereditary fiefs of Bavaria. In 1146, Henry himself took the reins of government, and at the diet of Frankfurt, in the following year, he demanded of the Emperor Conrad the restoration of the whole duchy of Bavaria, which had been wrested from his father. This was refused, and Henry at once, in concert with his uncle, had recourse to arms; but his efforts were crushed by the energetic measures of Conrad. After the death of this emperor, however, Bavaria was given up to him by his cousin, the Emperor Frederick I. His possessions now extended from the North Sea and the Baltic to the shores of the Adriatic, Eastphalia and Westphalia, with Engern, and the old duchy of Saxony from the Rhine to the Elbe, acknowledged his authority. The greater part of Bavaria belonged to him as a hereditary fief, while his Italian vassals in the Guelfic dominions beyond the Alps took the oath of allegiance to him in 1157. In 1166, under the direction of Hartwig, Archbishop of Bremen, a league, comprising the bishops of Magdeburg, Halberstadt, and Hildesheim, and the markgrafs of Thuringia and Brandenburg, was formed against him; but the capture of Bremen, and the storming of Oldenburg by H., paralysed its designs. About this time he separated from his first wife, and married, despite the opposition of his mother, a daughter of Henry the Lion, who, soon after which event he undertook an expedition to Palestine. During his absence, his enemies were not idle, and even the Emperor Frederick displayed a decided want of good faith, conduct which H., on his return, however, had not forgotten, by quitting the imperial army during an Italian campaign, and thereby causing Frederick to lose the battle of Legnano, and forcing him to conclude a disadvantageous treaty. The emperor was essentially, and uniformly, strongly against the duke. The numerous enemies of the latter again combined against him; he was summoned to appear at three different diets, and refused, was put under the ban of the empire. By 1182 his fortunes were at so low an ebb, that he was forced to ask mercy of the emperor at Erfurt; but all that he could get was permission to retain his hereditary territories of Brunswick and Lüneburg, and even this was on the condition of his going into exile for three years. H., in consequence, betook himself with his family to England, but returned to Brunswick in 1184, where he lived quietly. On the departure of Frederick for Palestine in 1189, H. was again allowed to withdraw to England, but returned in 1189, and after a year's fighting, a peace was concluded between him and his enemies, by which a portion of his former territories was restored to him. He died at Brunswick in 1195. H. was a brave and generous prince, an indefatigable activity, but obstinate and passionate. What raised him above the princes of his time was his efforts to advance the commerce, industry, and comfort of his people, and to foster literature and science, and to convert people to the Byzantine, the Old, and the Western Churches. (Hannov. 1819).

HENRY, MATTHEW, an eminent Nonconformist divine, the second son of Philip Henry, one of the 2000 ministers who left the Church of England on the passing of the 'Act of Uniformity,' was born at Rood Mick Farmhouse, in Flintshire, October 18, 1662. Having qualified himself for the ministry, he began to preach in June 1686, and in 1687 was settled as pastor of a congregation of dissenters at Chester, where he continued for 25 years. In May 1711, he was removed to a church near London, having refused two previous invitations from the same congregation. He died of apoplexy, June 22, 1714, while on his return from a visit to his old friends at Chester. He was twice married, and had a large family by his second wife. His principal work is an Enquiry of the Old and New Testament, in 5 vols. folio, 1710, commenced in November 1704, and has been often reprinted. He died to finish on the Acts of the Apostles. The remainder was completed by various ministers, whose names are given in some of the editions. His first publication, entitled A Discourse concerning the Nature of Sins, 34 pages, 1680, appeared anonymously in 1680. He was also the author of a biographical sketch of his father, 1693; A Scripture Catechism, 1702, 8vo; Communicant's Companion, 1704, 8vo; Discourses against Vice and Immorality, 1708; A Method of Prayer, 1710, 8vo; Family Constitution; numerous sermons; and some religious tracts. His miscellaneous works were republished at London in 1830, 8vo.

HENRY, PATRICK, an eminent American orator, was born in Hanover county, Virginia, in 1736. His father was a native of Scotland, and a nephew of Roberton, the celebrated historian. In early
HENRY—HEPTAGON.

Life. H. was passionately addicted to angling and hunting, and seemed too indolent to apply himself to any regular occupation. He managed, however, to pick up a good deal of general information, and he seemed to possess by intuition a profound knowledge of human nature in all its various phases. Having failed in an attempt successively in "store-keeping" and in farming, he at length induced to try the profession of law. For a few years this seemed to promise no better success than his former occupations. had done, but having been employed in 1755 to plead the cause of the people against an unpopular tax, his peculiar talent seemed suddenly to develop itself; his eloquence, untaught except by the inspiration of native genius, thrilled the audience, and held it in rapt attention more than two hours. From that moment to the present day he has been universally regarded as the greatest of American orators.

H. was a zealous patriot in the war of the revolution, and was one of the most prominent and influential members of the Virginia legislature, when that state was deliberating whether or not to join Massachusetts in forcibly resisting the arbitrary policy of the home-government. H. was a delegate to the first general Congress, which met at Philadelphia in September 1774, and his voice was the first to break the silence of that assembly. His eloquence on that occasion is said to have astonished all his hearers. In 1778, he was elected governor of Virginia, and in 1786 he was chosen a member of the convention to revise the Federal Constitution. He died in 1799.

HENRY, Robert, D.D., a Scotch historian and divine, was born at St Ninians, in Stirlingshire, February 18, 1718. He studied at the university of Edinburgh; and from 1756 till his death in 1790, was one of the ministers of the Established Church in that city. His History of Great Britain on a New Plan—the first volume of which was published in 1771, and the sixth in 1793, after his death—is a respectable performance, and the "new plan" on which it professes to be written—viz., that of embracing the social aspects of successive periods, and thus tracing the progress of civilisation in Great Britain—was unquestionably an improvement on anything that had been done before; but the work has no pretensions to critical acumen or even strict accuracy, and consequently is now of little value.

HENRY, William, F.R.S., an eminent chemist, was born in 1774 in Manchester, and died in 1836 at Pendlebury near that city. After studying medicine in the Manchester Infirmary, under the guidance of Dra Percival and Ferriar, H. attended the lectures of Black, Gregory, &c., in Edinburgh, in the session 1795—1796. After an interval of several years, in which he was chiefly engaged in superintending a chemical business which had been established by his father, he returned to Edinburgh in 1805, and received the degree of Doctor of Medicine from that university in 1807. Prior to that time till shortly before his death, he devoted himself to the allied subjects of chemistry and medicine. He was the author of nine papers in the Philosophical Transactions (chiefly on the chemistry of the gases); and his Elements of Experimental Chemistry, in two volumes, which was published in 1799, reached an eleventh edition in 1829, an almost unparalleled success for a purely scientific work. H., like Dr Wollaston, made the results of science, obtained by the most original and different researches, the foundation of a splendid fortune, and few persons have contributed more effectually by the application of their discoveries to the promotion of the arts and manufactures. The Memoirs of the Manchester Society are chiefly indebted to him, and to Dalton for their high scientific character.

HEPAR (Gr. hepar, the liver) is the name given by the older chemists to various compounds of sulphur, from their brown, liver-like colour; of these, Hepar sulphuris, which is in reality a mixture of tarsus and iodine, and some oxysulphuric acid of potash, is the best known. HEPATICA, belonging to the liver: as, hepatic artery, vein, duct, &c.—HEPATICA. This term has been given by writers on materia medica to medicines which affect the liver and its appendages. The hepatica may be employed (1) to modify the secretion of bile; (2) to remove pain of the liver or gall-bladder, or pain and spasm of the gall-ducts; or (3) to relieve enlargements and other affections of the liver.

HEPATICA, or LIVERWORTS, a natural order of cryptogamous plants, included among mosses by the older botanists. They have generally a leafy stem; more rarely they are expanded into a leaf-like form. The reproductive organs are of two kinds, antheridia and pistillidia, as in mosses; the spore-cases (capsules, matured pistillidia) open by no operculum; open when ripe by 4—8 valves, more rarely by teeth; and generally contain, along with the spores, spiral filaments called elaters. Each elater consists of two spiral fibres, which, whilst the spore-case is unbroken, remain coiled up together within an oval cell; but when, by the breaking of the mature spore-case, the outer pressure is removed, their elasticity bursts their cells, and as they suddenly extend themselves, they aid in the dispersion of the spores. The H. are found in situations generally similar to those of mosses; and are widely distributed over the globe; but the greater number belong to warm climates, where they often grow on the bark, and even on the leaves of trees. Some botanists divide H. into three orders, Japerrmanniaceae, Marchantiaceae, and Ricciaceae.

HEPATITIS (Gr. hepar, the Elater and Spores of liver), inflammation of the liver.

Hepatitis is a rare disease in temperate latitudes, and in tropical climates is often so acute and so rapidly fatal as to admit but little of medical treatment. It is indicated by pain in the right side and shoulder, tenderness on pressure in the right hypochondrium (see ABDOMEN), with enlargement of the liver as detected by the hand and by percussion, often vomiting, always fever, with more or less loss of appetite and a foul tongue. Not unfrequently there is Jaundice (see V.). The disease sometimes ends in abscesses, which may require to be opened externally. The treatment is complicated, and cannot be ventured upon without professional assistance. The other diseases of the liver will be treated of under LIVER, DISEASES OF.

HEPHESTUS. See Vulcan.

HEPTAGON, a plane figure of seven sides and seven angles; when the sides and angles are equal, the figure is a regular heptagon. Geometers have
HEPTARCHY—HERACLEITUS.

litherto failed to discover a method of inscribing the heptagon in, or of circumscribing it about a circle, and the problem is believed by many to be, like 'the trisection of an angle,' impossible of solution by the ancient geometry. 

HEPTARCHY, THE, is the name given to seven kingdoms said to have been established by the Saxons in England. See ANGLO-SAXONS. The common idea is, that these seven kingdoms were conquered by kings; but all that can be safely asserted is, that England, in the time of the Saxons, was peopled by various tribes, of which the leading occupation was war; and that sometimes one was conquered, sometimes another. At no time was there a combination of the seven, as the ancients, so that they could be said to have a separate, much less an independent existence. Still, seven names do survive (some authorities adding an eighth), the king of the one that had the fortune to be most powerful for the time being, being styled Bretwalda or ruler of Britain, but in most instances the power of this supposed ruler beyond the limits of his own territory must have been very small. Under Egbert, Wessex rose to be supreme, and virtually followed up the work of his predecessors. The following is a brief account of the seven kingdoms commonly said to have formed the Heptarchy: 

1. Kent, after the battle of Crecanford, in which 400 Britons were slain, was abandoned by the Britons, and became the kingdom of their conquerors, a band of Jutes, who had come in 446 A.D. to serve Vortigern, king of the Picteis, as mercenaries, under the leadership of Hengist and Horsa, who were brothers. Hengist became king of Kent, and his son Eric or Aesc succeeded him, and from him his descendants, the kings of Kent, were called Aescingas. In 796, Kent was conquered by Cenwulf, king of Mercia; and about 825, both Kent and Wessex were conquered by Egbert, king of Wessex, who appointed his son Ethelwulf king of Kent, which hereafter, though separate in name, was really subordinate to Wessex.

2. Sussex, partially conquered about 477, and wholly, before 491, by Eila the Saxon, who was the first Bretwalda of Britain. Sussex submitted to Egbert of Wessex in 828, and his son Athelstan governed it under him.

3. Wessex, though fluctuating in extent, as all the kingdoms did, included Surrey, Hants, the Isle of Wight, Berks, Wilts, Dorset, Somerset, Devon, and part of Cornwall. It was founded about 494 by Cerdic and Cyric his son, 'Ealdhormen' or leader of the 'old Saxons.' King Egbert, who returned from a flight to Gaul in 806, and ruled from that year till his death in 836, was, as a conqueror, the most successful of all these Saxon kings. When he died, his dominions were divided between his sons, Ethelwulf and Athelstane, the former taking Wessex Proper, and the latter Kent, Essex, Sussex, and Surrey. Another Athelstan, who succeeded in 923 to Mercia and Wessex, conquered Exeter, and assumed Northumbria, exacted tribute from the Welsh, and some formal submission from the Britons of the west, as well as the Danes and Scots. He appears occasionally to have held witenagemotes or Saxon parliaments of subordinate chiefs (subregina), and at one of these, Constantine, who was at first separate, assumed the title of subregina. But Athelstan and his successors, as well as his predecessor, Alfred the Great, belong to the history of England, as indeed do all the Saxon states and kings after Egbert.

4. Essex, which comprised also Middlesex, if ever independent, was so about 530 A.D.; but early in the 7th c. it became subject to Mercia, and fell with it to Wessex in 823. This state and Sussex and Wessex were founded by the old Saxons; the remaining three by the Angles who came from Holstein, and gave their name to England.

5. Northumbria consisted of Bernicia and Deira, which 432 AD. were separate and independent states. The former comprised Northumberland and all Scotland south of the Forth, and was founded by Ida about 569. The latter comprised Cumberland, Durham, York, and Lancaster, and was founded by Ella the Anglian, about the same time. These two were united about 655, and as Northumbria, they submitted to Egbert in 829.

6. East Anglia, comprising Norfolk, Suffolk, and Cambridge, was founded about 571 by Ulla, and from him its kings were named Ulfings. In 883, it was conquered by the Danes, and was only restored to Saxon rule by Athelstan in 925.

7. Mercia included the counties in the centre of the kingdom, and is said to have been founded by Crida or Creoda in 583. Three-quarters of a century later, it was conquered for a time by Northumbria, but it recovered its independence, and retained it until Egbert subdued it. Canute the Dane conquered it in 1015. Just before Edmund Ironside's death allowed him to become king of England, and the Danes to obtain the ascendency over the Saxons, for which they had been striving, at intervals, for five generations, See ANGLO-SAXONS. See also HERALDRY, and the Rise and Progress of the English Commonwealth (2 vols. Lond. 1832).

HERA. See JENQ.

HERACLEIA, an ancient city of Magna Graecia, situated on the right bank of the Acherus (the modern Agri), about three miles above the mouth of that river in the Gulf of Tarasutum. It was founded about 483 B.C., and although under the Romans it became a prosperous, important, and refined city, it never acquired any historical prominence. When it fell into decay, it is not known, but at the present day little more remains to mark its site than heaps of rubbish. In the neighbourhood, besides a large number of coins, ranking among the very finest relics of antiquity, there have been discovered certain bronze tables, known as the Table of Heracleia, containing a copy of the LEX THALAMONIAE (about 270 B.C.), and forming the basis of the principal authorities for a knowledge of the municipal law of ancient Italy. This inscription has been published by Muratori, Savigny, and others.

HERACLEIDÆ. This term means, in its widest sense, all the 'descendants of Hercules' (Hercules), of whatever time, and in whatever district of Greece, but is specially applied to those adventurers who, founding their claims on their supposed descent from the great hero (to whom Zeus had promised a portion of the land), joined the Dorians in the conquest of the Peloponnesus. There were five different expeditions, the last and greatest occurring eighty years after the Trojan war. The leaders of this last were Temenus, Creshphontes, and Aristodemus, the last of whom was a grandson of Capaneus, hero at Thebes; and thus gained possession of Argos, Sparta, and Mycenae. The other parts of the country quickly submitted to them, and they then proceeded to divide the country among themselves. Temenus fell to Temenidae; Creshphontes to Procles and Eurytheneis, the sons of Aristodemus; and Messenia to Creshphontes. This story of the return of the Heracleids touches on the historical period, and though there is much of fable and tradition, yet there seems to be also a large substratum of truth in the records. See Müller's Dorians, Thirlwall's, and Grote's Greece.

HERACLEITUS, a Greek philosopher, was born at Ephesus, in Asia Minor, and flourished about 500.
Heraclius—Herald.

As he is said to have travelled much, and to have been very sorrowfully impressed with the weakness of his fellow-creatures, whence, according to old traditions, he obtained the nick-name of the 'weeping philosopher,' in contrast to Democritus, 'the laughing philosopher,' he resorted to the study of science. He was born at the city of Avari, and had two brothers named Stanes and Democditus. The result of his researches and meditations was a work on the nature of things, said to have been entitled Peri Physeis (On Nature). Such fragments of it as were discovered and elucidated by Schleiermacher in Wolf and Buttman's Museum der Alterthumswissenschaften (vol. i. part 3, Berlin, 1805). From these, it appears that he considered fire to be the first principle of all phenomena, and that he sought for an explanation of the laws of nature, which has all been evolved. He was not a very original nor a very coherent thinker, and his speculations deserve little attention.

Heraclius, a Byzantine emperor (610—641), of splendid but fitful genius, was descended from a line of brave ancestors, and was born in Cappadocia about 575 A.D. His father, also named Heraclius, was eunuch or governor-general of Africa. Regarding H.'s youth we know almost nothing; but when unbending, his eye was fixed, his hand steady (which proved successful) against the emperor Phocas, whose horrible cruelties had made him universally detested. In 610, H., at the head of a fleet, appeared at Constantinople: the citizens rose in rebellion; Phocas was beheaded, and H. was crowned emperor in his stead. His fellow-conspirators were richly rewarded. The condition of the Byzantine empire at this time was deplorable. Fractions within and the barbarians without had almost reduced it to nothing; for ten years' warfare had put forth any vigorous efforts for its reorganisation. His most powerful enemies in the north were the Avari, who, in 619, plundered the country to the very gates of Constantinople: H., at first, tried to negotiate with his enemies, but flushed with their triumphs, they refused, and even put his ambassadors to death. Probably, the emperor, who was now laying his plans for taking a magnificent revenge on the Persians, was not greatly displeased at their refusal. Having, after a whole year of laborious discipline, organised an army composed of Greeks and barbarians, he, in 622, shipped his troops to the Bosporus, and sailed for the Hellespont. Having landed, he encamped in the plain of Issus, completely routed a Persian army despatched against him, and forced his way through the passes of the Taurus and Anti-Taurus, into the province of Armenia, where he was met by the envoys of the kings of Persia and of Armenia, and of the 'Caucasian tribes.' He crossed Armenia, conquered several of the Perso-Caucasian countries, and reached the Caspian Sea. Here he formed an alliance with the khan of the Khazaras, who ruled over the steppes regions north of the Caucasus, as far as the river Ural. By the assistance of these and other barbarians, he attacked Media, and carried his arms as far south as Isphahan. Before going into winter-quarters, he again utterly defeated the main body of the Persians, commanded by Chosroes himself. In 625, H. descended from the Caucasus into Mesopotamia, and thence proceeded to Cilicia, where a sanguinary engagement took place between him and Sarbar; the Persians were routed with immense slaughter, and Sarbar fled to Persia. During the next two years (626—628), the glory of H. culminated. He carried the war into the heart of the Persian empire, and in December 627, cut to pieces the forces of the Persian king, and was made sultan general, near the junction of the Little Zab and the Tigris. An immense booty fell into the hands of the victors. A few days after, H. took Armenia or Dastagerd, the favourite residence of Chosroes, and here to his enmity were quite relaxed; and before the close of his life, Syria, Palestine, Mesopotamia, and Egypt were in the hands of the califs. H. died in 641.

Herald (derivation uncertain), an officer whose duty consists in the regulation of armorial bearings, the marshalling of processions, and the superintendence of public ceremonies. In the middle ages, heralds were highly honoured, and enjoyed important privileges; their functions also included the bearing of messages, whether of courtesy or defiance, between royal or knightly personages; the superintending and registering of trials by battle, tournaments, jousts, and all chivalric exercises; the computation of the slain after battle; and the recording of the valiant acts of the falling and the victorious. The office of herald is probably as old as the origin of coat-armour. The principal heraldic officers are designed kings-of-arms or kings-at-arms, and the novitiates or learners are styled pursuivants. Heralds were originally created with much ceremony; they are now appointed by the Earl Marshal in England, and by the Lyon King-of-arms in Scotland. There are now in England three kings-at-arms, named by their offices Garter, Clarenceux, and Norroy; six heralds—Somerset, Chester, Winchester, Richmond, Lancaster, and York; and four pursuivants, called Rouge Dragon, Portcullis, Blue Mantle, and Rouge Crux. The heralds have no official connection with the districts from which they take their titles, and there have been at different periods other heralds, whose titles are now laid aside; heralds extraordinary have also sometimes been created, as Edmonson, by the title of Mowbray, in 1794. In Scotland, the principal heraldic officer is the Lyon King-at-arms; and there are six heralds—Snowdown, Albany, Ross, Rothesay, Marchmont, and Ilay; and five pursuivants—Unicorn, Carrick, Kintyre, Ormond, and Bute. Ireland has one king-at-arms, Ulster; two heralds, Black and Dublin; and two pursuivants, of whom the senior bears the title of Athlone, and the other is called the pursuivant of St Patrick.
HERALDRY.

The official costume of a herald consists of an embroidered satin tabard or surcoat of the royal arms, and a collar of SS See King-at-arms, Purveyor, Heralds' College.

HERALDRY is properly the knowledge of the various arms and marky duties devolving on a herald (see Herald); in the more restricted sense, in which we shall here consider it, it is the science of armorial bearings. After occupying for ages the attention of the learned, and once an important branch of a princely education, the study of heraldry fell, in later times, into neglect and disrepute, and was abandoned to coat-painters and undertakers, a degradation owing in part to the endless tissue of follies and mystications that had been superinduced with it. Modern criticism has rescued heraldry from the pedantries and follies of the heralds, and imparted to it a new interest, as a valuable aid to historical investigations.

Though we have instances in remote times of nations and individuals distinguishing themselves by particular emblems or ensigns, nothing that can properly be called armorial bearings existed before the middle of the 12th century. The shields of the French crusaders in the first crusade presented a plain face of polished metal, nor is there any evidence of heraldic devices having been in use in the second crusade in 1147. But the Anglo-Norman period, when the fleur-de-lis flourished in the latter part of the 12th c., mentions devices or cognizances as being in use among the Normans, "that no Norman might perish by the hand of another, nor one Frenchman kill another;" and Wace is curiously corroborated by the Bayeux tapestry of the 12th c., where there are figures of animals on the shields of the invaders, while the Saxon shields have only borders or crosses. The rude devices on these shields have nothing approaching to an armorial form or disposition, yet it is probable that systematic heraldry sprang out of them, but it is difficult to say when they assumed that hereditary character which is essential to the idea of armorial bearings. Some sort of armorial insignia were depicted on the shields used in the third crusade, which took place in 1189; and in the same half century originated the fleurs-de-lis of France and the lions of England. The transmission of arms from father to son seems to have been fully recognised in the 13th c., and in the practice then introduced of embroidering the family insignia on the surcoat worn over the hauberk or coat of mail, originated the expression coat of arms. Arms were similarly embroidered on the jupon, cyclas, and tabard, which succeeded the surcoat, a practice which survived till the time of Henry VIII., when the tabard came to be entirely disused except by heralds, who still continue to wear on their tabards the royal arms.

It was by slow degrees that the usage of arms grew up into the systematise form which it assumes in the works of the established writers on heraldry. The principal existing data for tracing its progress are English rolls of arms yet extant of the times of Henry III., Edward I., and Edward III. The earliest formal treaties date no further back than the end of the 14th c., before which time the whole historical part of the subject had been obscured by a time in which it has misled most subsequent writers up to a very recent period. The professors of the science represent the heraldry of the 10th and 11th centuries as equally sharply defined with that of the 13th and 16th. The arms of William the Conqueror and his sons are described with all their differences; arms are ascribed to the Saxon kings of England, to Charlemagne, and even to half-mythical persons and heroes of classical times. It is rather surprising to find this fictitious heraldry understood and systematised early in the 14th century. The arms traditionally considered to be those of Edward the Confessor were sculptured in Westminster Abbey in the reign of Edward II., and in the infancy of heraldry, every knight assumed what arms he pleased, without consulting sovereign or king-at-arms. Animals, plants, imaginary monsters, things artificial, and objects familiar to pilgrims, were all fixed on; and whenever it was considered necessary, emblems were added which sufficed resemblance in sound to suggest the name or title of the bearer of it. There is reason to believe that early arms were generally armes paralouse, and regulations laid down by the late kings for the transmission of arms to be intelligible from the old name of the object being forgotten. The charge fixed on was used with great latitude, singly or repeated, or in any way which the bearer chose, or the form of his shield suggested. But as coats of arms became more numerous, confusion often arose from different knights adopting the same symbol; and this confusion was increased by a practice which crept in of sovereigns or feudal chiefs allowing their arms, or part of them, to be assumed by their followers as a mark of honour by their favourite followers in battle. Hence different coats of arms came in many instances so closely to resemble each other, that it was imperative, for distinction's sake, that the fancy of the bearer should be restrained, and regulations laid down by the sovereign for the position of the charges, and the attitudes of the animals represented. This necessity led, in the course of time, to the systematising of heraldry, a process which took place by degrees, and was progressing on gradually throughout the 13th and 14th centuries. By the time that heraldry was consolidated into a science, its true origin had been lost sight of, and the credibility and fertility of imagination of the heralds the allusion to the most common charges with mystical meanings, and to trace their original adoption to the desire of commemorating the adventures or achievements of the founders of the families who bore them. The legends ascribing an origin of this sort to the early armorial bearings have nearly all instances where it has been possible to investigate them, turned out to be fabrications. It was only when heraldry began to assume the dignity of a science, that augmentations of a commemorative character were allowed. One of the earliest, known instances being the heart added to the coat of Douglas on his carrying the heart of Robert the Bruce to Palestine. After the science became systematised, augmentations and augments were often granted with a reference to the supposed symbolical meanings of the charges.

In England, the assumption of arms by private persons was first restrained by a proclamation of Henry V., which prohibited every one who had not borne arms at Agincourt to assume them, except in virtue of inheritance or a grant from the crown. To enforce the observance of this rule, heraldic visitations or processions through the counties were instituted, and continued from time to time till the reign of William and Mary. See Visitatio of Arms.

Jurisdiction in questions of arms is executed by the Herdicks' College in England, the Lyon Court in Scotland, and the College of Arms in Ireland. No one within the United Kingdom is entitled to bear arms without a heraldic claim by descent, or a grant from the competent authority; and the wrongful assumption of arms is an act for which the assumer may be subjected to penalties. See Herald's College, and Lyon Court. The use of arms, whether rightfully or wrongly, subjects the bearer of them to an annual tax. It is illegal to use without authority not only r coat of arms,
Heraldry.

but even a crest. Any figure or device placed on a heraldic wreath (see WREATH) is considered a crest in questions with the Herbals' College or Lyon Court, as well as in questions with the Commissioners of Inland Revenue. It shews how deeply the passion for outward display has entered into human nature, when we find people in countries such as the United States, where all differences of rank are theoretically repudiated, assuming heraldic devices, and adorning themselves with heraldic or other emblems.

Besides individuals, communities and states are entitled to the use of arms, and herbals have classified arms, in respect of the right to bear them, under the following ten heads: 1. Arms of dominion; the arms borne by sovereigns annexed to their territories. 2. Arms of pretension, which sovereigns have borne, who, though not in possession, claim a right to the territories to which the arms belong.

Thus, England bore the arms of France from the time of Edward III. till 1601. 3. Arms of community; the arms of bishops’ sees, abbeyes, universitites, towns, and corporations. 4. Arms of assumption; arms which one has a right to assume with the approbation of the sovereign; thus, the arms of a prisoner at war may be borne by his captor, and transmitted by him to his heirs. 5. Arms of patronage; added by governors of provinces, lords of the manor, patrons of benefices, &c., to their family arms, as a sign of right of superiority, right of quarter. 6. Arms of succession, borne quartered with the family arms by those who inherit tithes or manors, either by will, entail, or donation. Thus, the Dukes of Atholl, as having been lords of the Isle of Man, quarter the arms of that island, and the Dukes of Argyll quarters the arms of the lordship of Lorn.

7. Arms of alliance, taken up by the issue of heiresses, to shew their maternal descent. 8. Arms of adoption, borne by a stranger in blood, to fulfill the will of a testator. The heir of a family may adopt the arms to bear his name and arms and possess his estate. Arms of adoption can only be borne with permission of a sovereign or king-at-arms. 9. Arms of concession; augmentations granted by a sovereign of part of his royal arms, as a mark of distinction, a usage which, we already observed, obtained in the earliest days of heraldry; and hence the prevalence among armorial bearings of the lion, the fleur-de-lis, and the eagle, the bearings of the sovereigns of England and Scotland, of France, and of Germany.

10. Paternal or hereditary arms, transmitted by the first possessor to his descendants.

A coat of arms is composed of charges depicted on an escutcheon, representing the old knighthly shield. The word escutcheon is derived from the French escu, which signified a shield with armorial bearings, in contradistinction from écu, a shield generally. The shields in use in England and France in the 11th and 12th centuries were in shape not unlike a boy’s kite, a form which seems to have been borrowed from the Sicilians; but when they became the recipients of armorial bearings, they were gradually flattened and shortened. From the time of Henry III., the escutcheon has been most frequently represented overall as of something approaching to a triangular form, with the point downwards, the chief exceptions being that the shield of a lady is lozenge-shaped. Thus, it is a knightly device of square. To facilitate description, the surface or field of the escutcheon has been divided into nine points (fig. 1), technically distinguished by the following names: A, the dexter chief point; B, the middle chief; C, the sinister chief; D, the honour or collar point; E, the fess point; F, the nembir or madow point; G, the dexter base point; H, the middle base; and L, the sinister base point. It will be observed that the dexter and sinister sides of the shield are so called from their position in relation not to the eye of the spectator, but of the supposed bearer of the shield.

Costs of arms are distinguished from one another not only by the charges or objects borne upon them, but by the colour of these charges, and of the field on which they are placed. The field may be of one colour, or of more than one, divided by a partition line or lines varying in form. The first thing, then, to be mentioned in blazoning a shield—that is, describing it in technical language—is the colour, or, as it is heraldically called, tincture of the field. Tinctures are either of metal, colour strictly so called, or fur. The metals used in heraldry are two—gold, termed or, and silver, argent—represented in painting by yellow and white. The colours are five—red, blue, black, green, and purple, known as gules, azure, sable, vert, and purpure. Metals and colours are indicated in uncoloured heraldic engravings by points and hatched lines, an invention ascribed to Father Silvestro di Petraracanta, an Italian herald of the 17th century. Or (fig. 2) is represented by points;

![Fig. 2](image)

...
ruis, being, according to some heralds, not laid on the shield, but ensus or sewed to it.

Everything contained in the field of an escutcheon is called a charge. Charges are divided by heralds into the three classes of honourable ordinaries, sub-ordinaries, and common charges. Under the name of ordinaries or honourable ordinaries are included certain old and very frequent bearings, whose true peculiarity seems to be that, instead of being taken from extraneous objects, they are representations of the wooden or metal strengthenings of the ancient shields. They are ten in number: 1. The Chief (fig. 3), the upper part of the shield separated from the rest by a horizontal line, and comprising, according to the requirements of heralds, one-third of it, though this proportion is seldom rigidly adhered to.

2. The Pale (fig. 4), a band or stripe from top to bottom, said, like the chief, to occupy one-third of the shield. It has two diminutives, the Pallet, one-half in breadth of the pale, and the Endorse, one-half of the pales.

3. The Bend (fig. 5), a similar band crossing the shield diagonally from dexter chief to sinister base. Its diminutives are the Bendlit or Garter, one-half of its breadth; the Cost or Costie, one-half of the bendlet; and the Riband, one-half of the cotise. The bend is sometimes borne between two cotises, in which case it is said to be Couped, a term sometimes applied with doubtful propriety to the other ordinaries when accompanied with their diminutives.

4. The Bend sinister, a diagonal band from sinister chief to dexter base. Its diminutives are the Scarpe, one-half of the bend sinister; and the Baton (fig. 6), one-half of the scarpe. The baton stops short of the extremity of the field at both ends, and has been considered a mark of illegitimacy.

See BASTARD BAR.

5. The Fess (fig. 7), a horizontal band in the middle of the shield, said, like the ordinaries already enumerated, to occupy one-third of it. Its principal diminutive is the Bar, containing the fifth part of the field; and there are also the Claret, one-half of the bar, and the Burrete, one-half of the closest, the latter seldom borne singly.

6. The Chevron (fig. 8), composed of two stripes descending from the centre of the shield in diagonal directions like the rafters of a roof. Its diminutives are the Cherune, one-half, and the Coupe-close, one-fourth its width, the latter borne, as its name implies, in pairs, and generally accompanying the chevron—on each side of it.

7. The Cross (fig. 9), uniting the pale and fess, an ordinary which was originally like the rest, composed of the clamps necessary to the strength of the shield, but had also the deeper meaning of the symbol of the Christian faith. Besides its plain form, the cross was varied in numerous ways, most of these varieties being, however, rather common charges than ordinaries. Of the 39 lesser crosses mentioned by Guillem, and 106 by Edmonson, a few of the most frequently occurring are the following: the Cross moline (fig. 10), with the ends turned round both ways; the Cross fleury (fig. 11), of which each limb terminates in a fleur-de-lis; the Cross patee (fig. 12), each limb of which has three points; the Cross potent (fig. 13), crutch-shaped at the ends; the Cross pattée (fig. 14), small in the centre, but widening towards the ends; and the Cross croiset (fig. 15), crossed at the ends. The latter is the most frequent of all, and borne often in numbers than singly. Any of these crosses is said to be jitchè, when the lower limb terminates in a sharp point, as in fig. 16. There is also the Cross Maltese, whose limbs have each two points, and converge to a point in the centre of the cross; though not frequent as a heraldic charge, it derives an importance from being the badge of the Knights of Malta and of many other orders.

8. The Saltire, or St Andrew's Cross (fig. 17), formed by a junction of the bend dexter and bend sinister.

9. The Pile (fig. 18), a wedge with the point downwards. A single uncharged pile should, at its upper part, occupy one-third the breadth of the shield, but if charged, it may be double that width.

10. The Quarter, consisting of the upper right-hand fourth part of the shield cut off by a horizontal and a perpendicular line. Its diminutive is the Canton (fig. 19).

Armorial figures may be depicted on any of these ordinaries, but not on their diminutives, with the exception of the canton.

We observed that the field of an escutcheon may be of two different tinctures, divided by a partition-line, which line may vary in direction. When divided by a partition-line in the direction of one of the ordinaries, the shield is said to be Party per that ordinary; thus we may have (figs. 20) a shield party per pale, bend, fess, chevron, or saltire. An escutcheon divided as by a cross is said to be quartered. A shield divided into any number of parts by lines in the direction of a pale, bend, or bar, is said to be Pola, Bendy, Barry, the number of pieces being specified, as in the example fig. 21, barry of six, argent and gules. When the field is of a metal and colour separated by any of two lines of partition, and the charge placed on it is said.
HERALDRY.

to be Counter-changed: this means that the part of the charge which is on the metal is of the colour, and vice versa, as in fig. 22, the arms borne by Chaucer the poet, the pale argent and gules, a bend counter-changed.

The partition-line which bounds the field, or the boundary-line of an ordinary, is not always even. Fig. 23 represents the commonest forms of irregular partition-lines in use, viz., the engrailed, inverted, wavy, nebule, embattled, sable and dancette. An ordinary engraillé has the points of the engraillé line turned outwards, and an ordinary inverted, inwards. Dancette differs from the indented by the partition-line being marked with only three indications.

The Subordinaries, or subordinate ordinaries, are, generally, enumerated as the following, though there is no very broad line of demarcation between them and the common charges. 1. The Gyron.—When a shield is at once quartered and party per saltire, as in fig. 24, the division is called Gyronny of eight (from gyro, a circle), and one of the triangles, or at least the triangle in dexter chief, is a gyron. Gyronny of six, ten, or twelve also occasionally occur, so called according to the number of the triangles. 2. The Fret (fig. 25) is a cognizance derived from the banding or ornamenting of the shield, and a shield covered with this lattice-work decoration (fig. 26) is said to be Fretted. 3. The Bordure, or border (fig. 27), is a stripe encircling the shield. It is much used to distinguish different branches of a family, and is often charged with small devices, on which account it has sometimes been reckoned an honourable ordinary. 4. The Orle (fig. 28) differs from bordure in not touching the extremity of the shield. 5. The Trellis, regarded as a diminutive of the orle, is generally borne double, and flory counter-flory, as in the arms of Scotland, or, a lion rampant within a trellis flory counterflory gules (fig. 29). 6. The Pall (fig. 30), the archiepiscopal ornament of that name, sent from Rome to metropolitans, and resembling in form the letter Y. 7. The Pinnacle (fig. 31), the dexter and sinister sides of the shield cut off by a curved line. Flanches are always borne in pairs, and sometimes charged. 8. The Lozenge, a figure of four equal sides, with the upper and lower angles acute, and the others obtuse. 9. The Fusil (fig. 32), longer and more acute than the lozenge. 10. The Rivet (fig. 33), a lozenge pierced round in the centre. 11. The Mascle (fig. 34), a lozenge perforated, and shewing a narrow border. Mascles were probably originally links of chain-armour.

A field is said to be Lozengy (fig. 35), Fusil or Mascally, when divided by diagonal lines in the direction of these subordinaries. A field divided by horizontal and perpendicular lines into squares of different tinctures, is said to be Chequy; in the case of a FEsn chequy there are three such rows of squares.

Among subordinaries are sometimes reckoned certain circular charges called Roundels or Roundlets, distinguished in English heraldry by different names according to their tinctures. When one or more, they are called Bezants; of argent, Plates; of gules, Tortoises; of azure, Hrots; of purpure, Gulpes; and of sable, Ogres or Pellets.

We now come to the third class of figures occurring in armorial bearings. We have seen that the ordinaries and subordinaries are for the most part purely heraldic figures, connected in their origin with the shield itself; the common charges, on the other hand, are representations more or less conventional of familiar objects, which have no necessary relation to the shield; but are in some way emblematic as concerns family or individual history and character. The knights, in the early days of heraldry, ransacked the animal, the vegetable, and the mineral kingdom, as well as the range of things natural and artificial, for cognizances which would be distinctive, and at the same time suggestive, of the name or title of the bearer of them. We can only enumerate a few of the charges of most frequent occurrence.

Of beasts, the Lion requires special mention. The king of beasts is one of the most frequent of heraldic devices, and is made to assume a great variety of attitudes, for which see Lion. Lions and other beasts of prey are said to be armed or langued of any tincture when their teeth and claws, or their tongue, is of that tincture. With some change of colour or position, the royal beast came to be used by all who could claim kindred, however remote, with royalty, and lions were further multiplied by augmentations granted by the sovereign to his favourite followers. The heraldic leopard, which has been the subject of much controversy, was originally but another designation for the lion passant-gardant. Bears, boars, bulls, stags, are favourite heraldic beasts. A stag walking is said to be bipennant; he is at gaze when a lion would be statant-gardant; he is attired of any tincture when his horns are of that tincture. The animals that possess horns and hoofs are said to be armed and unguled in respect of them. The heads and limbs of animals are often borne as charges, and they may be either coupé, cut off in a straight line, or erased, cut off with a jagged edge.

Of birds, we first see the eagle. The sovereign of birds, and symbol of imperial Jove, was, next to the lion, the most favourite cognizance of royal personages, and was adopted by the German emperors, who claimed to be successors of the Cæsars of Rome. The imperial eagle had at first but one head; the monstrosity of a second head seems to have arisen from a dimidiation of two eagles, to represent the eastern and western empire. The eagle of heraldry is most generally displayed, i. e., its wings are expanded; sometimes it is preying, or standing devouring its prey. The aileron, the cognizance of...
HERALDRY.

...the duchy of Iorraine, and the family of Montmorancy, was originally but a synonym for the eagle assumed (M. Planché suggests) as an anagram for the word Lorainns, but modern heralds have degraded it into a nondescript creature without beak or claws. The martlet was originally a martin, a species of swallow, which has also in course of time been assumed by heralds of its legs and beak. The pelican, the swan, the cock, the falcon, the raven, the parrot or popinjay, and the peacock, are all of tolerably frequent occurrence. The pelican has generally her wings addorsed, or placed back to back, and is depicted pecking her breast. When in her nest feeding her young, she is called a pelican in her pity. A peacock borne antioxid with his tail expanded, is said to be in his pride. Birds of prey are armed of the colour of which their beak and talons are represented. Such as have no talons are beaked and monteured. The cock is said to be armed, crested, and jelled, the latter term referring to his comb and gills. Birds having the power of flight are, in respect to their attitudes, close, rising, or volant.

Fish and reptiles occur as charges: the former are said to be annuit, if drawn in a horizontal, and annuata in a perpendicular position; and the dolphin, in reality straight, is conventionally borne embowed or bent. The escutosh shell is of frequent occurrence, and said to be the badge of a pilgrim. Sometimes the conventional heraldic form of an animal differs from its true form, as in the case of the antelope of heraldry (fig. 36), which has the head of a stag, a unicorn's tail, a tusk issuing from the tip of the nose, a row of four horns down the back of the neck, and similar tufts on the tail, chest, and thighs. Of 'animals phantastic' we have among others the grphon, wyvern, dragon, unicorn, basilisk, harpy. We have the human body in whole or part, a naked man, a savage or wild man of the woods, also arms, legs, hearts, Moors' heads, Saracens' heads, and that strange heraldic freak, the three legs conjoined, carried in the escutcheon of the island of Man.

Of plants, we have roses, trefoils, cinquefoils, leaves, garls (i.e., sheaves of corn), trees, often eradicated or fructated of some other colour, and above all, the celebrated fleur-de-lis, used as a badge by Louis VII. of France. The meaning of heraldry is hard to explain. When a plant, animal, or other charge is blazoned proper, what is meant is that it is of its natural colour. The heavenly bodies, the sun, moon, and stars, are also pressed into the service of heraldry, as are things inanimate and artificial without number, particularly such as were familiar to the warriors and pilgrims of the twelfth and thirteenth centuries. Helmets, buckles, shields, hatches, horseshoes, swords, arrows, battering rams, pilgrims' staves, mullets (or spur-rowsels), and water-lougets, or bags, in which in crusading times water was carried long distances across the desert, also the clarion or war-trump, generally and erroneously called a rest. Even the letters of the alphabet have been used as charges.

Charges may be placed either simply on the field or on one of the ordinaries; in some instances, one of the ordinaries is placed over a charge, in which case the charge is said to be detoured by the ordinary. Three charges of one kind are placed two above and one below, unless blazoned in fas or in pale. In the fourteenth and fifteenth centuries, the supposed heraldry began to be departed from by accumulating a variety of charges on one shield, and in later times we have sometimes a charge receiving another charge like an ordinary. The growing complexity of shields arose from augmentations granted to distinguish the younger branches of a family, or charges assumed from the maternal coat by the descendants of an heiress. In the end of the last, and beginning of the present century, a practice prevailed for a time of introducing into armorial bearings matter-of-fact landscapes, representations of buildings, and medallions and decorations worn by the bearer, setting all heraldic conventionalities at defiance, and dealing in details not discernible on the minutest inspection. Such charges are frequent in the arms of the heroes of the old war; as, for example, in the augmentation granted to Sir Alexander Campbell, Bart, in addition to his paternal arms—viz., 'a chief argent charged with a rock proper, subjoined Gibraltor, between two medallions that on the Dexter representing the silver medal presented to Sir A. Campbell by the supreme government of India, for his services at the storming of Seringapatam, in 1799; that on the sinister representing the gold medal presented to him for his services in the battle of Talavera.' The grants proceeding from the present kings of arms are more conformable to the usages of heraldry, and do not stand in need of such lengthened explanations to understand.

The arms of the different members of a family have been distinguished from one another, sometimes by the use of a bordure or other difference; and sometimes, especially by English heralds, by the use of certain figures called marks of cadency, the label, crescent, mullet, martlet, annulet, fleur-de-lis, to designate the eldest, second, third, fourth, fifth, or sixth son and his descendants—an invention originating about the time of Henry VII., but which cannot consistently be carried through the ramifications of a family for a succession of generations. See CADENCY.

Blazonry is an essential part of the science of arms. To blazon a coat is so to describe it that any one with an ordinary knowledge of heraldry will be able to depict it correctly. In the language of blazonry, all tautology must be avoided. The tincture of the field is first mentioned; the ordinary, if any, follows, unless it be a chief; then the charges between which the ordinary is placed. The charges on the ordinary follow, and lastly we have a canton or chief, and marks of cadency. The rules of blazonry are given in the article BLAZONING OF ARMS.

Besides the heraldic devices depicted on the shield, there are the following borne external to it—the helmet, the mantling, the wreath, the crest, the motto and scroll, the supporters, and the coronet.

The helmet, originally a piece of defensive armour, became in the course of time one of the usual accompaniments of the shield; and placed over the arms, it came by its form to mark the rank of the wearer. For these distinctions, which are of comparatively recent date, and applicable only to British heraldry, see HELMET.

The mantling is an embellishment of scroll-work flowing down on both sides of the shield, and originating in the cointoise, or scarf, wrapped round the body in the days of coat-armour.

From the centre of the helmet, within a wreath of two pieces of silk of the two principal tinctures, the armorial bearings, issues the crest, originally a special mark of honour worn only by heroes of great valor, or advanced to a high military command; now an inseparable adjunct of the coat of arms in English, and often assumed or changed arbitrarily without proper authority.

The scroll, placed below the shield, contains a
HERALDS' COLLEGE—HERBARIUM.

**Nobs**, bearing in many cases an allusion to the arms of the family or arms. **Supporters** are figures or animals standing on each side of the escutcheon, and seeming to support it. They were in their origin purely ornamental devices which only gradually acquired a heraldic character. In England, the right to use supporters is confined to the royal family, peers, peersesses, and peers by courtesy, Knights of the Garter, Knights Grand Cross of the Bath, and a very few families whose ancestors bore supporters before their general use was restricted. In Scotland, supporters are also used by the baronets of Nova Scotia and the chiefs of various families.

The crown of the sovereign, the mitre of the bishop, and the coronet of the nobility, are adjuncts appended to the shield of those whose dignity and office entitle them to that distinction. For a description of the crown of Great Britain and the coronet of the royal family, see article **CROWN**. Under the articles DUKES, MARQUIS, EARLS, VISCOUNT, and BARON, the coronets appropriated to the different ranks of the nobility are described.

The subject of **marshalling arms** or arranging various coats in one escutcheon, is explained in a separate article. A husband is entitled to **inspale** the arms of his wife, i.e., to place them on the same shield side by side with his own. When the wife is an heiress, the husband bears her arms in an **inspale**, or small escutcheon in the centre of his own shield, and the descendants of the heiress may quarter her arms with their paternal coat. A sovereign also quarters the arms of his several states, and feudal arms are sometimes quartered instead of the sovereign's arms. It may place his hereditary arms on an escutcheon of pretence over the insignia of his dominions.

For information on the details of heraldry, references are made to the standard works of Guillim, Elmsley, and Niasle, and for a more discriminating view of the subject, to such recent treatises as Montague's Herality, and Planché's **Perns of Arms**.

HERALDS' COLLEGE, or COLLEGE OF ARMS, a collegiate body, founded by Richard III. in 1483, consisting of the heraldic officers of England, who were assigned a habitation in the parish of All-hallows-the-Less, in London. Various charters confirmed the privileges of the College of Arms, and it was incorporated by Royal Charter in 1856, who bestowed on it Derby House, on whose site in Doctors' Commons the present college was built by Sir Christopher Wren.

The presidency of the college is vested in the earl marshal, an office now hereditary in the family of Howard Duke of Norfolk; he nominates the three kings of arms, six heralds, and four pursuants, who are the members of the collegiate chapter. Persons having a hereditary claim to arms are also suo jure, and if any one or more generations, are empowered by the Herals' College to assume them, on proof and registration of pedigree. A person who has no hereditary claim, and wishes a grant of arms, must make an application. The heralds, if satisfied, make a grant of arms or armorial bearings and issue for the same.

HERAT, capital of the most westerly of the three divisions of Afghanistan, stands on the river Heri, at the height of 2500 feet above sea level, about 34° 50'N., long. 62° 30'; E; distance from Kabul, 390 miles west. Situated near the boundaries at once of Afghanistan, Persia, and Independent India. A few miles to the east of the city, lies the site of the principal city of Afghanistan, now occupied by the capital of the Afghan government. The city itself, two miles in length, is very ancient, and has been repeatedly burnt and razed to the ground. The ruins of its ancient walls extend over a vast extent of country, and are seen over a considerable distance. The extreme depth of the vale of Herat is about 400 feet, and the town is situated on the left bank of the river Helmand, which runs through the city, and falls into the Oxus, a little below the town of Bokhara. The town is built on a steep hill, and is defended by a strong wall, with about forty gates to the entrance. The descent from the hill to the river is abrupt and precipitous, and is guarded by a strong stone bridge. The town is remarkable for its extent, and for the number of its inhabitants, who are chiefly Persians and Afghans. The annual revenue of the town is estimated at 50,000 rupees. The town is a great cattle mart, and is famous for its wool and cotton. The population is about 10,000 souls, exclusive of the army garrison, which is not less than 10,000 men. The town is governed by a mayor, who is appointed by the British government. The British are stationed here in considerable numbers, and are divided into two companies, viz., the 55th and 87th regiments of foot.

HERALD, a maritime department in the south of France, bounded on the south-east by the Gulf of Lyon, is oval in form, and is 84 miles in greatest length from east to west. Area, 2436 square miles; pop. (1866) 400,424. It is occupied in the north and north-west by the Lower Cevennes, from which several branches of moderate elevation run toward the south. virtually subsiding as they approach the sea. The principal rivers are the Herault, from which the department derives its name, the Orb, and the Lez, which, rising in the Cevennes, pursue a generally southward course to the Mediterranean. The coast-line is about 66 miles in length; and along the shore, from Agde to the Vendre, are numerous estuaries, or marshy lakes, united by a canal. The estuaries and harbours are well adapted for shipping. The town of Herault is situated on the coast, and is a good harbour. The town is old and well built, and is celebrated for its wool and cotton manufactures. The population is about 10,000 souls, exclusive of the army garrison, which is not less than 10,000 men. The town is governed by a mayor, who is appointed by the British government. The British are stationed here in considerable numbers, and are divided into two companies, viz., the 55th and 87th regiments of foot.
HERBERT. This name, which stands forth prominently upon the records of British history, has been ennobled at various times, in so many of its branches, by so many ancient and renewed creations, that it has become a matter of difficulty to ascertain with certainty which is the parent stem; though Sir Bernard Burke is inclined to give the representation of the House to the Right Honourable H. A., M.P., of Muckross, co. Kerry. It is certain that the Herberths came over to England in the train of William the Conqueror, for H., Count of Vermandois, who afterwards filled the post of chamberlain under the latter, is mentioned in the Roll of the Bailiff of Westminster Abbey, and received from his sovereign a grant of lands in Hampshire. His wife Emma, daughter of Stephen, Count of Blois, was a granddaughter of the Conqueror, and his son H. (called in history H. of Winchester) was chamberlain and physician to King Henry I. Seven or eight generations later, we find the Herberths diverging into several distinct branches, including the lines of the Earls of Pembroke (now extinct in the male line), of the Lords H. of Cherbury (also extinct), the Herberths of Muckross (ancestors of the gentleman mentioned above), and also several untitled branches which have flourished upon their ancestral lands in England, Wales, and Ireland. In the reign of Henry II., William H. of Haglan Castle, co. Monmouth, received the honour of knighthood in reward of his valour in the French wars. His eldest son, a staunch adherent of the House of York, was created Earl of Pembroke* by Edward IV. in 1469, but fell in the battles of the Lancastrians after the battle of Dunes Moor, and was beheaded the following day, when the title became extinct. It was, however, revived in 1551.

* The earldom of Pembroke was originally conferred on Richard de Clare, the celebrated Strongbow, who aided Henry II. in the conquest of Ireland.
in the person of his (illegitimate) grandson, William H., K.G., one of the most influential noblemen of his age, and one who took an active part in public affairs, both as a statesman and as a soldier. It is recorded by Sir B. Burke, that he rode on February 17, 1552—1553, to his mansion of Baynard's Castle, with 300 horse in his retinue, 100 of them being gentlemen in plain blue cloth, with chains of gold, and badges of a dragon on their sleeves. He was buried in Old St. Paul's, and his funeral was conducted on such a scale of magnificence that, according to Stowe, the mourning given away on that occasion cost £2000—a very large sum in those days. By his wife, who was a sister of Catharine Parr (the last queen of Henry VIII.), he had a son, Henry, second earl, K.G., to whose countess, Mary, daughter of Sir Henry Sydney, K.G., Sir Philip Sydney dedicated his Arcadia. She is celebrated by Ben Jonson in the well-known lines—

Underneath this marble_ears
Lies the subject of all—
Sydney's sister, Pembroke's mother.

The fourth earl, some time Lord Chamberlain to Charles I., and Chancellor of the university of Oxford, was the founder of Jesus College in that seat of learning. The eighth earl held several high offices, including that of lord High Admiral. From him the present earl of Pembroke (George Robert Charles H., born in 1850) is directly descended. The late Lord Herbert (q.v.) of Lea—better known as Mr Sidney Herbert—was the younger brother of the late, and father of the present earl. The Earls of Carnarvon, more than one of whom have gained celebrity in the field of literature, descend from the eighth Earl of Pembroke; and the present Earl of Powis is descended from the same stock materially, the only child and heiress of the last Earl of Powis of a previous creation having married the eldest son of the illustrious Robert Clive, the founder of our Indian Empire, in whose favour that title was renewed in 1864.

HERBERT, Edward, Baron H. of Cherbury, who is commonly reckoned the first of the English deistical writers, was born of a noble family in the year 1581, at Montgomery Castle, in North Wales. His Autobiography, published early in his life, shows his love for inquiry and his scrupulous truthfulness. He was sent to Oxford in his twelfth year, and before he had quite quitted his studies, he married an heiress. On the occasion of the coronation of James I., he was made a knight, and invested with various offices. Although his marriage was happy enough, there appears to have been little warmth of affection between him and his wife, who was considerably older than himself. He left home, accordingly, for travel in France in 1608, and from this time resided very much abroad. In Paris, he lived on terms of intimacy with the Constable Montmorency, Jean Casamon, and other distinguished men. After a brief return to his native country, he set out again in 1610 for the Low Countries, where he joined the army of the brave Maurice of Orange. For this prince he contracted a great affection, and again offered him his services in 1614. After a campaign, he travelled through Germany and Italy on horseback, and went as far as Venice, Florence, and Rome. On his return, he got into trouble from an attempt which he made to raise a detachment of Protestant soldiers nominated for the Duke of Savoy. Shortly after, he returned to England, and proposed to devote himself to study and philosophical inquiry; but high and important diplomatic duties awaited him. He was made a member of the Privy Council, and sent to France as extraordinary ambassador. His aim was to promote the alliance between France and England, and he was so far successful that he was appointed ordinary ambassador, and continued to reside at Paris. He tried, but without much success, the difficult task of negotiation between Louis XIII. and his Protestant subjects. He was elevated first to be a peer of Ireland, and then in 1630, five years after the accession of Charles I., to be a peer of England, with the title of Baron of Cherbury. When the civil war broke out, he appears to have acted with hesitation, at first siding with the parliament, and then joining the king. His hereditary seat, Montgomery Castle, was attacked and burned. He died in London in the year 1648.

The character of H., as depicted in his Autobiography, is in the main that of a gallant adventurer, equally fired with the love of arms and of arts, at once a soldier and a scholar. He is the gay man of the world, always truthful, honourable, and high-spirited; yet he has thoughts above those of the world; he ponders deeply the great questions of truth and religion, and has left us the result of his speculations in his two treatises, De Fertilitate and De Religione Gentilium. The reader will find an admirable analysis of the first and most important of these treatises in Hallam's Literary History. They are only interesting to the philosophical student, or to the inquirer into the religious side of modern society. Their significance is that of a philosophical dogmatist rather than of a critical inquirer. His arguments are abstract and deductive, and not analytical or negative. He offers solutions, rather than starts difficulties or obtrudes negations; and in this respect H. is rightly reckoned the first of English deists, the writings of all of whom partake more or less of the same character; although it is not easy to trace any links of direct connection between him and the outburst of deistical literature in the end of the 17th and beginning of the 18th century.

HERBERT, George, an English poet, and fifth brother of Lord Herbert of Cherbury (q.v.), was born in Montgomery Castle, Wales, on the 5th April 1633. He was educated at Westminster, and was sent to Trinity College, Cambridge, about 1651. In 1614, when he was elected fellow of the university, he was promoted to the office of public orator. At the university, he made the acquaintance of Lord Bacon; and in the hope of preference, he was induced to spend a considerable portion of his time about the court. On the death of James I., he studied divinity, and finally took holy orders. He was made prebendary of Leighton Bromswold in 1626. He married in 1630; and in the same year, received the rectory of Beemerton. Two years after, at the early age of 39, he died of the effects of a chronic ague. His principal poetical production, printed in 1633, a year after his death, is entitled The Temple, Sacred Poems and Private Elegiaca, and, although distinguished by fantastic conceits, contains several passages of the purest pious verse which the language possesses. He wrote a prose work, The Country Parson, which lays down rules for the guidance of a clergyman's life, and which may be considered a pendant to The Temple. His life was written by Izaak Walton, and to that quaint and loving pen, even more than to his own Temple Songs, he owes his immortality.

HERBERT, Lord, of Lea (Sidney Herbert), minister and statesman, son of the eleventh Earl of Pembroke by his second wife, was born at Richmond.
HERBS—HERCULES.

1830. Educated at Harrow and at Oriel College, Oxford, he devoted himself to public life, and entered the House of Commons in 1832 as member for South Wiltz, which he represented until his elevation to the peerage in 1861. He began his political career as a Conservative, and was Secretary to the Admiralty in Sir E. Peels administration from 1841 to 1845, when he became Secretary-at-war. As a member of this administration, it fell to him to oppose Mr Coblen's motion for a select committee to inquire into the effect of the corn-laws on farmers, and afterwards, to argue in support of free trade in corn. He went out of office with his party in 1846. In 1852 he was again Secretary-at-war, under the Aberdeen ministry, and, in consequence, the 'horrible and heart-rending sufferings' of the army before Sebastopol were laid in a great degree at his door. He was for a few weeks Colonial Secretary in the first administration of Lord Palmerston in 1855, and Secretary-at-war in his second administration in 1859. Great improvements in the sanitary condition and education of the army, the amalgamation of the Indian with the royal army, and the organisation of the volunteer force, signalised his army administration. He largely reformed the War Office, and was devoted himself with equable zeal and intelligence to his ministerial duties, when, owing to failing health, he resigned his seat in the House of Commons, and in 1861 was called to the Upper House, under the title of Baron Herbert of Lea. But release from labour came too late, for he died August 2, 1861. He was heir-presumptive to the twelfth Earl of Pembroke. He had great aptitude for business, winning and genial manners, great readiness and facility in debate, and a boundless energy. He was a liberal patron of the arts; and his Byzantine church at Wilton, near his splendid abbey-seat in Somersetshire, will remain a lasting monument of his taste and munificence. He married, in 1846, the daughter of Major-General A'Court, niece of the first Lord Heytesbury; and his eldest son, born in 1850, is now Earl of Pembroke and Montgomery.

HERBS, or HERBACEOUS PLANTS, in Botany, are those in which no persistent woody stem is formed above ground. In some, the stem is woody, being annual. There is, however, in many a permanent woody rhizome or root-stock.—In books of gardening, plants used only for flavouring are sometimes distinguished as sweet herbs, as mint, basil, &c.; whilst those valued for their nutritive qualities are known as pot herbs.

HERCULANEUM, an ancient city of Italy, was situated at the north-western base of Mount Vesuvius, about five miles east of Naples. Considerable obscurity envelops its early history; it is supposed, however, to have been of Phenician origin, and to have been occupied afterwards by Pelasgians and Oscans. It subsequently was conquered, with all the rest of Campania, by the Samnites, and later it fell into the hands of the Romans. In 63 B.C., the city was seriously injured by an earthquake and in 79 A.D. it was buried, along with Pompeii and Stabiae, by the memorable eruption of Vesuvius (q.v.) which took place in that year. It now lies at a depth of from 70 to 120 feet below the surface, and is flattened, and covered with volcanic tufa, composed of sand and ashes, and consolidated to some extent by water, which is often thrown up in great quantities during volcanic eruptions. Above it, on the modern surface, are the two large villages Portici and San Costanzo. In the latter, in 1706, on the occasion of deepening a well, fragments of mosaics were first brought up; but little was done in the way of systematic excavation till 1798, when explorations were commenced under royal authority. It was then discovered that the building near the bottom of the well, from which the first relics were obtained, was the theatre. This building was forthwith explored and cleared, and several statues, both in bronze and marble, were extracted from it. Excavations were carried on but to a limited extent, not only in consequence of the hardness of the tufa, but from the fear of undermining the dwellings on the surface. Hence visitors can see only a very small portion of this entombed city. The chief edifice shewn is the theatre, which had been very large, and was built but a short time before the fatal eruption. It has 18 rows of stone seats, and could accommodate 8000 persons. A basilica, two small temples, and a villa, have also been discovered; and from these buildings, many beautiful statues and remarkable paintings have been obtained. Among the art-remains of H., which far exceed in value and interest those found at Pompeii, may be mentioned the statues of Ajax, Agrippina, the Sleeping Faun, the Six Actresses, Mercury, the group of the Satyr and the Goat, the busts of Plato, Scipio, Africanus, Augustus, Seneca, Demosthenes, &c. These treasures, together with such vases and domestic implements as have been found, have been conveyed to the Museum at Naples. Latterly, the portion of H. towards the sea, which had been covered only by loose ashes, has been laid open, and ancient buildings are now seen there to advantage as at Pompeii. See Some-
ting of Italy, by W. Chambers, 1862.

HERCULES (Gr. Herakles), called likewise Alcides, after his grandfather Alces, was the son of Zeus and Alcmeone, and the most celebrated hero of the Greek legends, the ideal of human perfection, as conceived in the heroic ages; i. e., the greatest physical strength, connected with every high quality of mind and character which these ages recognised. He had a bitter enemy in Hera, who, knowing that the child who should be born that day was fated to rule over all the descendants of Perseus, contrived to prolong the travail of Alcmeone, who was the daughter of Alceus, son of Perseus, and was born that of the wife of Sthenelus, another son of Perseus, who, after a pregnancy of seven months, gave birth to a son, named Eurystheus. Eurystheus thus, by decree of Fate, became chief of the Perseids. Pindar and other subsequent writers relate, that, while yet in his cradle, H. shewed his divine origin by strangling two serpents sent by Hera to destroy him. By Amphitrion's care, he was instructed in all arts by the first masters. Amphitrion now sent him into the country, where he tended the flocks till he was 18 years of age. During the

Gate at Herculanum.
HERCULES,

period, as the Sophist Prodikos relates in his poem, H., meeting the goddesses of Pleasure and Virtue at the crossways, chose the latter to be the constant companion of his life. His first exploit was the slaying of a lion, which haunted Mount Citharon, and ravaged the dominions of King Theseus. H. was kindly received by the king, and at length succeeded in destroying the lion. On this exploit, the inhabitants of the city immediately set up a statue of the conqueror, and only freed it from the disgrace of having to pay tribute to the Orchemaionians, but compelled them to pay double the tribute which they had formerly received. In return for this service, Creon, king of Thebes, gave him his daughter, Mago, in marriage. At this time, Eurytheus summoned H. to appear before him, and ordered him to perform the labours which, by the order of Zeus, he was to accomplish in his own children by Megara. When he recovered his senses, he returned, submitted to Eurytheus, and addressed himself to the performance of the labours imposed upon him. The first labour was to carry the golden apple, located on the island of the Hesperides, and which were guarded by the serpent Python. The second was to destroy the Lernean Hydra, which he accomplished with the assistance of his friend Iolaus; but because H. obtained a serpentine staff which could not be wounded by the arrows of a mortal, he boldly attacked him with his club, but in vain; and he was finally obliged to strangle him with his hands. From this time, he became the father of Jason, in addition to his own children by Megara. The third was to slay the Nemean Lion, and which could not be wounded by any weapon. The fourth was to make the beast of Marathon a bear, which ravaged the neighbourhood of Ermanthes. The fifth was to clean the stables of Augias, king of Elis, where 3000 oxen had been confided for many years, which he accomplished in one day, by turning the rivers Alpheus and Peneus through the stables. But as H. had gone to Augias, and offered to perform the labours of Heracles, he was compelled to do the work of the latter, and it was assumed that he had been commanded to perform it by Eurytheus, the latter, hearing of this, judged that it must not be counted as one of the labours. His sixth task was to destroy the constantly moving mountain, which was turned to stone, and which he must overthrow, and which he turned into a sea. The seventh was to bring alive to Peloponnesus a bull, remarkable for his beauty and strength, which Poseidon, at the prayer of Minos, had given to Minos, king of Crete, in order that he might sacrifice it, which Minos afterwards refused to do, Poseidon made the bull mad, and it laid waste the island. H. brought the bull on his shoulders to Eurytheus, who set it at liberty. It appears again as the Marathonian bull in the story of Theseus. The eighth labour was to obtain the horses of Diomedes, king of the Bistones in Thrace, which fed upon human flesh. The ninth was to bring home the hide of the Nemean Lion, which was guarded by the leopard. The tenth was to kill the monster Geryon, and bring his herds to Aegos. These were all the labours which were originally imposed on H., but as Eurytheus declared the second and fifth unlawfully performed, H. was ordered to perform two more. The eleventh was to obtain the golden apples from the garden of the Hesperides. Atlas, who knew where to find the apples, brought them to H., who meanwhile supported the vault of heaven; but according to others, H. went himself and stole the apples, after slaying the dragon who guarded them. The last and most dangerous labour was to bring from the infernal regions the three-headed dog Cerberus. When H. promised him Cerberus, he added the proviso that he should not employ arms, but only force. When H. had brought the monster to Eurytheus, the latter, pale with fright, commanded him to be removed. H. set him at liberty, whereupon Cerberus returned into the nether world. H. was now free from his state of servitude.

To these well-known "twelve labours," must be added many other achievements, such as his battles with the centaurs and with the giants; his participa- tion in the capture of the Golden Fleece; the liberation of Prometheus and Theseus, &c. After accomplishing all these exploits, H., while in a state of mental aberration, murdered his faithful friend, Iphitus; he was afterwards purified from the murder; but was compelled to sell himself for three years into slavery. When his period of slavery had expired, he returned to Peloponnesus, and some time afterwards became a suitor for the hand of Dejanira, the daughter of Eneas, king of Calydon, whom he married, after having overcome his rival Achelous. With her he now repaired to Trachinia. Having arrived at the river Euenus, he encountered the centaur Nessus. H. perceived that the centaur was about to offer Nessus the benefit of carrying Dejanira over, attempted to offer her violence; whereupon H. slew him with an arrow dipped in the poison of the Lernean hydra. Nessus, before expiring, instructed Dejanira how to prepare a love-potion for Hercules. The hero now made war against Eurytos (king of Oechalia, who had defrauded him), slew him and his sons, and carried off his daughter Iole. Thence he went to Kennes in Eubea, and erected an altar to Zeus Kennes, in order to obtain the favor of the god. Honors were conferred on him by the people of Trachinia, and his body was buried with all the honors due to a hero. He became reconciled to Hera, and married Hebe.

According to most mythologists, there were several heroes of the name of Hercules. Among these are an Indian, an Egyptian, a Tyrian or Phenician, and a Thasian Hercules. The last is the most celebrated, and to him the actions of the others have possibly been attributed. Others, who would explain the story of H. symbolically, pretend that it conceals an astronomical idea; while others discover in this myth the history of the early development of Greece. On the astronomical hypothesis, the twelve labours of H. are simply the course of the sun through the twelve signs of the zodiac, which the plastic poetry of the Greeks has converted into a legend. According to Max Muller, H. was the Sun-god, and the legend of his death symbolizes the sunset: 'In his last journey, H. proceeds from east to west. He proceeds from the Kennes promontory to Trachis, and then to Mount Eeta, where his pile is raised. The coat which Dejanira sends to the solar hero is an expression frequently used in other mythologies, it is ... the clouds which arise from 391
the waters, and surround the sun like a dark \_raiment. H. tries to tear it off, i.e., his fierce splendour breaks through the thickening gloom, but fiery mists embrace him, and the burning pair of the scorching rays of the sun, and the dying hero is seen through the scattered clouds of the sky tearing his own body to pieces, till at last it is consumed in a general conflagration.' Comparative Mythology, in the Oxford Essays, 1856. Festivals were celebrated in honour of H., at which his exploits were sung. In this manner arose the Heraclea, long poems celebrating the life and actions of Hercules. H. is represented in plastic art as the ideal of a hero. Strength is the characteristic idea, which has been developed by the sculptors Myron and Lyssippus in a form not to be surpassed. A complete series of representations of the twelve labours may be seen in the vases of Volce. The conflict with the giants very frequently occurs on vases of the oldest style; the one on the casket of Cypselos is particularly worthy of notice. H.'s figure is generally youthful.

HERCULES, Pillars of, the name given by the ancients to the two rocks forming the entrance to the Mediterranean at the Strait of Gibraltar. Their erection was ascribed by the Greeks to Hercules, on the occasion of his journey to the kingdom of Geryon. According to one version of the story, they had once been united, but Hercules tore them asunder, to admit the flow of the ocean into the Mediterranean; another version represents him as causing them to unite temporarily, in order to form a bridge. The pillars are not mentioned in Homer, though he speaks of Ulysses' passage out of the Mediterranean into the ocean and back, shewing an apparent knowledge of the existence of the strait. The first author who mentions them is Pindar, who places them at Gades (Cadiz), and his opinion had many followers in later times. The most general opinion, however, identified them with Calpas (now Gibraltar) and Abyla (now Ceuta).

HERCULES BEETLE (Scarabaeus Hercules, or Dynastes Hercules), a coleopterous insect of the family Lamellidexes and tribe Scarcubeidae, remarkable not only for its great size—it being five inches long—but for the singular appearance of the male, an enormous horn projecting from the head, and being opposed by a similar but smaller projection of the thorax, the whole resembling a pair of great but somewhat unequal pinces, the body of the insect is the handle. It is a native of Brasil.
HEREDITY.—HEREDITARINESS.

Ideal humanity, it might almost be said, is his divinity, in whose service he labours with restless zeal. That enthusiasm, however, which made H. so effective as a mover of men's minds, had its fatal consequence, in a deficiency of artistic excellence. His writings have not that fine perfection of style and method which will enable them to float down the stream of time unmolested. Among his other works may be mentioned his 'Days and Nights,' a fragment of a tale that has been written and republished a purely hereditary instinct. 'Exactly in the same way,' he adds, 'we find in man peculiarities of mind, temper, thought, habit, volition, &c., appearing and reappearing. He has traced some of his grandfather's writing exactly resembling his own (which is very peculiar), though the grandfather had died before he was born, and his father was quite different.' It is alleged that the children of skilled actions are mere apt at petty manipulations than the children of ordinary labourers, and that hence the population of certain towns—Birmingham, for example—has a great advantage over that of other towns in point of manufacturing industry.

It is well known that longevity or the reverse, a tendency to great fruitfulness or to sterility, peculiarities in the degree of delicacy in the external senses, and a special talent, and a certain disease, as gout, pulmonary consumption, &c., &c., are frequently transmitted in hereditary descent from one or other parent to the offspring. The predisposition to any special disease may be transmitted by either parent; but when both parents have been affected, the offspring are especially liable to suffer from it. Deformities and diseases, also, engendered by circumstances to which the exposure is lifelong, or affecting successive generations, are also hereditary.

Hereditary Tendency to Mental Disease.—As the mental constitution in general is eminently propagable, the hereditary tendency in mental disease is more familiar and better demonstrated than in other forms of morbid actions. One observer attributes six-sevenths of the cases of insanity to this cause. In France, and among the affluent classes, one case in every three; among the peasants, one in every ten, is found to occur in families predisposed to alienation. In Italy, the proportion is nearly the same. When stating that derangement is traced to transmitted taint, expression is given to the complex proposition, that individuals who have inherited unhealthy cerebral organisation, or diseases, such as anaemia, incompatible with sound mental action, fall victims more frequently and inevitably to insanity than those physically and mentally robust would do. Experience shows that as particular forms of physical degeneration, such as rickets, consumption, in like manner particular species of alienation, are propagated in families; that the suicidal impulse appears in one, while the uncontrovertible and insatiable desire for stimulants, is the heritage of a third. There are certain laws by which this propensity seems to operate. Not merely are there more females than males actually insane, but there are more hereditarily disposed to be insane. In connection with this it must be observed that women are more exposed by constitution to the exciting causes of insanity than males, and that as infants they more readily acquire the mental tone of the mother. But, in short, the influence of the hereditary tendency is frequently transmitted than that of the father. French authorities record that of 467 cases of mental affections, 279 were traceable to the mother; an English physician similarly records 76 out of 153. Where the taint exists on the side of the mother, a greater number of children, and a greater number of daughters, are born of unsound mind. But this disposition to disease of the nervous matter is manifested in the same family.
HEREDITARY PRIVILEGES AND POSSESSIONS—HEREFORDSHIRE.

in various forms—in one member suffering under epilepsy, another under mania, another under eccentricity or delusions. Even the last are exhibited in successive generations. Oxford, who fired at the Queen, his father and grandfather, all believed themselves to be St Paul—Holland, Medical Notes &c.; Lucas, L'Herédité Naturelle.

HEREDITARY PRIVILEGES AND POSSESSIONS.

The question of the advisability of hereditary rights and privileges has been much argued. Their objects are three, especially in more recent times. The first is hereditary monarchy. The "divine" right of kings is now little urged, being felt to be incompatible with modern notions of the political relations of society; and the defence that hereditary transmission of the supreme power of the state is rather rested on the ground of political expediency and necessity. The animosities and disturbances of public affairs that attend the ever-recurring elections are a signal instance of the state are assured, it is argued, by making power hereditary in a particular family, and by a determinate law of succession; while the dangers and disadvantages which might arise from an authority depends, the chance of birth, are capable of being neutralised by institutions which prevent the monarch from doing harm, even if there were not every reason to hope that self-interest will lead him to use the power which is the birth-right of his family. Without government honor and advantage of that family, and, therefore, of the community with which it is indissolubly bound up.

Another and perhaps more difficult aspect of the question is with regard to hereditary classes. The transmission of offices in the state over and above the hereditary monarch. One thing is now universally agreed upon, that the transmission in individual families of dignities, rights, and offices, involving essential parts of government, such as the supreme dispensation of justice, and other attributes of sovereignty, is inconsistent with the very idea of a state. The splitting up of Germany into a maze of petty sovereignties arising out of fields of the empire because hereditary, is a signal instance of the dangers of this principle. A hereditary nobility with such rights is no longer considered defensible. It is another question whether, as a political institution, a class with certain hereditary privileges may not be advantageous or even necessary as an element of stability, and as affording a source of trained statesmanship. Society has a longer life than the individuals that compose it, and should have further-stretching views— "looking before and after;" and it is chiefly in the great historical families of a nation, that such extended views grow up and are cherished—families whose traditions form part of the national history, and which naturally identify their future with the national prosperity and dignity. Besides their traditions and well-developed national instincts, the individual members of such families enjoy other advantages as political and social leaders. Their usually good education, and their well-secured possessions which, in addition to a high sense of honour, raise them above having recourse to petty shifts and jobs, make them valuable as examples and as administrators in a commonwealth which aims at dignity and stability. Carried to an extreme, it was the case in France prior to the great revolution, the hereditary privileges of the nobility became a source of social discontent and disorder; but limited as in the United Kingdom, hereditary privileges and dignities are found to be no way incompatible with the utmost social expansion, and are in reality so popular as to be admittedly a happy feature in the structure of society. It is further to be observed, that as great families with privileges and titles are from time to time dying out, while others, through distinguished public services, are raised to the rank of nobility, that degree of infusion of new blood kept up which gives vigour to the state, and at last prevents the British aristocracy from degenerating into an effete or antiquated caste. As regards the economic view of hereditary right to private property, see J. S. Mill's Political Economy.

HEREDITARY RIGHT, strictly speaking, means the right of succession as an heir-at-law. The essential part of this right is nothing but convenience, the principle being, that if a man does not by will appoint his own heir, the law will do it for him; and the law, in doing this, proceeds according to certain degrees of relationship. It is therefore a mistake to suppose that there is anything in mere hereditary right that is divine, or superior to that which results from the radical right of ownership. It is a secondary and substantial right, the principal and primary right being that by which the owner of land is entitled to say who shall at his death enjoy that land.

HEREFORD, a city, parliamentary and municipal borough, and capital of the county of the same name, is situated in the fertile and highly cultivated vale of the Wye, 134 miles west of London. The principal building is the cathedral, a noble edifice, 350 feet long, and 174 feet broad, commenced in 1079. A very interesting old map of the world, said to date from the 13th c., and other geographical works, are deposited in the charterhouse and library. Besides many other public buildings, H. contains numerous benevolent and educational institutions, among the latter of which are several important free schools. Among its manufactures, which, however, are inconsiderable, gloves, hats, and flannels are the chief. Of its five annual fairs, that held in October is perhaps the largest in the county for cattle and cheese. H. returns two members to the House of Commons. Pop. in 1831, 12,198; in 1861, 15,625.

HEREFORDSHIRE, an inland county in the west of England, is bounded on the W. by South Wales, and on the E. by the counties of Worcester and Gloucester. Area, 534,823 acres. Pop. (1861) 123,559. The surface of the county is hilly, with many affluents of the Severn. Among the chief affluents are the Wye, its affluents the Lugg, the Arrow, and the Teme, which are the principal rivers. The climate of H. varies with the elevation and the exposure, but, as attested by the general longevity of the inhabitants, is on the whole exceedingly healthy. The soil is for the most part a deep, heavy, red loam, which produces good crops of grain, chiefly wheat, and is highly favourable to the growth of trees. Oak and apple trees abound, and orchards are numerous, and cider is made in great quantity. Sheep and cattle of excellent breed are extensively reared, and in the north-west of the county a useful breed of horses is produced. Agriculture is the chief employment of the inhabitants.

H., or at least the greater part of it, formed a portion of the territory of the ancient Silures, and was conquered by the Romans in about 73 A.D. During the so-called Heptarchy, it was included in the district of Mercia. From its position on the Welsh border—a portion of the county being included in the debatable land called the 'Marches'—H. was among the scene of frequent contests.
HERCENIA—HERFORD.

HERCENIA, a town of Spain, in the province of Ciudad Real, and about 40 miles north-east of the city of that name. It carries on manufactures of soap, has a large weekly market and a population of 6400.

HERESY (Gr. Hairesis) primitively means a choice or election, and in its application to religious heresy is used to designate as well the act of choosing for one's self, and maintaining opinions contrary to the authorized teaching of the religious community to which one's obedience is due, as the heterodox opinions thus adopted and the party which may have adopted them. In the Acts of the Apostles (see Acts v. 17; xv. 5; xxiv. 5; xxviii. 22), the word seems to be used of a sect or party, abstracting from the consideration of its character whether good or bad; but in the Epistles and in the early Christian writers it is almost invariably used in a bad sense, which is the sense uniformly accepted in all subsequent theological literature. The notion of heresy, as understood by the early Christian writers, consists in two ideas: first, the deliberate and voluntary rejection of some doctrine proposed by the supreme authority established in any church as necessary to be believed; and secondly, a continuance of persistence in such rejection, with the knowledge that the belief of the doctrine is required of all the members of that particular religious community. Roman Catholic writers, regarding the authority of their own church as supreme and final, apply the name of heresy to any formal denial of a doctrine proposed by the Roman Catholic Church as necessary to be believed. Protestant writers seldom use the word, except in relation to what each sect regards as the essentials of Christian faith. Beyond this point, indeed, the notion of heresy may be extended, in the dogmastical system of the Protestant sects, especially in reference to other communions than their own. In the Roman Catholic Church, the supreme authority may be either the decree of a general council approved by the pope, or a dogmastic decree of the pope himself, expressly or tacitly received by the bishops of the various churches; and in general the crime of heresy is incurred in any church by the rejection of any doctrine which that church is held to constitute an essential and integral portion of the Christian faith. Apostasy is the complete abandonment of the whole Christian doctrine, and the renunciation of the Christian profession. If the intention to do this be accompanied with full deliberation, and by full knowledge of the motives of belief, the heresy is called formal; should it arise from ignorance or imperfect knowledge, it is styled material; and the heresy is held to be imputable, or the contrary, according as this ignorance is vincible or invincible.

Even in the apostolic times, heresies had arisen in the church, and before the council of Nice, the catalogue of sects had already swelled to considerable dimensions. Without attempting any enumeration of these heresies, it may be said in general that the sects of the early centuries are all reducible to two classes: (1) Those which attempted to associate the Christian doctrines with Judaism; (2) Those which ingrained Christianity upon the Gentile religions or the Gentile philosophies. And this latter class naturally subdivides itself into (1) The sects which were tinged with the errors of the oriental Jews, the Sabaeans, and the Gnostics; (2) Those which drew their errors from the Grecian schools. Of all these we find traces, more or less distinctly marked, in the sects of the later ages.

From the very date of the establishment of Christianity in the Roman empire, heresy appears to have been regarded as a crime cognizable by the civil law; and Constantine enacted several severe laws for its repression, which were continued and extended by his successors, and were collected into a single title, De Hereticis, in the Justinian code. The penalties of heresy ordained by these enactments are very severe, extending to corporal punishment, and even to death; and they all proceed on the distinct assumption that a crime against religion, is a crime against the state. These enactments of the Roman law were embodied in the various codes of the European kingdoms; and in considering the history of the later period it is necessary to recollect that the principle above referred to, as to the social bearing of the crime of heresy and of other crimes against religion, pervades the whole system of medieval jurisprudence. It is further to be remembered, that the principles of many of the medieval sects were anti-social and communistical, as well as opposed to the doctrines of the church; and that their leaders, in many instances, by adopting violent and revolutionary means for the propagation of their doctrines, drew upon themselves the punishment of anarchy and rebellion, as well as of heretodoxy in religion. Still, with even these allowances, Catholic historians themselves admit that the effects of the principles against heresy were in many instances excessive, as were, indeed, also the processes and penalties of the criminal code.

In English law (2 Hen. IV. c. 15), heresy consisted in holding opinions contrary to Catholic faith and the determination of Holy Church; and by common law the offender was to be tried in the provincial synod by the archbishop and his council; and, after conviction, was to be given up to the king to be burnt at his pleasure. It was not competent to issue a writ de hereticis conscribendo, but the statute above referred to empowered the diocesan to take cognizance of heresy, and on conviction, to hand over the criminal directly, and without waiting for the king's writ, to the sheriff major or other competent officer. This statute continued practically in force, with certain modifications, till the 29 Charles II. c. 9, since which time heresy has been entirely transferred to the cognizance of the ecclesiastical courts; but, as there is no statute defining in what heresy consists, and as, moreover, much of the jurisdiction of the ecclesiastical courts has been withdrawn by the various toleration acts; and, above all, as the effect of these decisions has been to widen almost indefinitely the construction of the doctrinal formulries of the English Church, it may now be said that the jurisdiction of these courts in matters of heresy is practically limited to preventing ministers of the Established Church from preaching in opposition to the doctrine and the articles of the establishment from which they derive their ordinances, and that, even in determining what is to be considered contrary to the articles, a large toleration has been judicially established. See the recent trial of Dr Rowland Williams, and the judgment given by Dr Lushington in the Court of Arches. For the history and literature of heretical sects, see the various ecclesiastical historians, as also Stockmann's Lexicon Haresinum (Leip. 1711); De Caussa's Herrenologica (Rome, 1736) ; Fritz's Ketzerlexicon (Wurzburg, 1834) ; Arnoldi et Ketzerhistoria (Frankfurt, 1795); Geschiedenisse der Ketzer (Leip. 1792); and Hilger's Darstellung der Haresien (Bonn, 1857).

HERFORD, a town of Prussia, in the province of Westphalia, is situated close to the frontier of the Westphalia, 17 miles north-west of Minden. Yarn-spinning, linen-weaving, and carpet manufactures are carried on. Pop. 9863.
HERIOT—HERMANDAD.

HERIOT, George, founder of a magnificent hospital at Edinburgh, the son of a goldsmith in that city, a descendant of the Heriots of Trauborn, East Lothian, was born about 1602, and admitted, in May 1588, a member of the Edinburgh Incorporation of Goldsmiths, he was, in 1597, appointed goldsmith to Anne of Denmark, consort of James VI. of Scotland, and soon after to the king. On the death of the latter, in 1603, to the English throne, he went to London, where, as court-jeweller and banker, he amassed considerable riches. He died February 12, 1624, without issue, and bequeathed the greater part of his wealth to the town-council and ministry of Edinburgh, to found and endow a hospital in that city for the maintenance and education of the sons of poor deceased or decayed burgesses. The noble structure of Heriot's Hospital, from a design, it is believed, by William Aytoun, though said to be by Inigo Jones, was completed, in 1642, at a cost of £30,000 sterling. After the battle of Dunbar, in 1650, Cromwell made it a depository and in 1658 it was restored to the governors by General Monk; and in 1659, 30 boys were admitted. 180 boys are now maintained and educated in it. In 1766 the annual revenue was £1900. In 1837 it amounted to £21,302, of which £12,173 was in the shape of £3000 a year. The yearly revenue is now about £15,000. Most of the ground on which the New Town of Edinburgh is built belongs to the hospital. The revenues greatly exceeding the expenditure, in 1837 an act of parliament was procured for the erection of schools in Edinburgh for the education of poor children, free of all expense. Of these 'Heriot Schools,' there are twelve—viz., eight juvenile and four infant schools—attended by upwards of 3000 boys and girls. All the revenues are devoted to these schools are those, in poor circumstances, of decasual burgesses and freemen, those of burgesses and freemen who are unable to provide for their support, and those of poor citizens and inhabitants of Edinburgh, who become destitute. The governors are also empowered to allow to any of the boys attending such schools, being sons of burgesses and freemen, a uniform fixed sum of money for the support of such boys in case the sum of money paid, after they have left the schools, all out of the surplus funds of the hospital.

HERIOT, in English Law, is a kind of fine due in copyhold estates to the lord of the manor on the death of the copyholder, and consists of the best beast, jet, or chattel that belonged to the deceased. The lord can enforce this right by action, or seize it brevi manu. Such a right is practically unknown in freehold estates in England. In Scotland, all land is held on much the same forms as copyhold; and much more vexatious things of a similar kind to heriots, under the name of reliefs, become due from a vassal's heir to the superior on the vassal's death. In both countries, the practice is equally barbarous.

HERISTAL, or HERISTAL, a village of Belgium, in the province of Liège, extends along the left bank of the Maas for about three miles, immediately below the city of Liège, of which it may almost be considered a suburb. Population about 7000, principally workmen, who find employment in the iron and steel works, which are here carried on. Some ruins still exist of the castle of Heristal, the birthplace of Pepin le Gros (father of Charles Martel, and great-grandfather of Charlemagne), and from which he had his title of Pepin of Heristal.

HERITABLE AND MOVABLE, a Scotch law term phrase denoting the distinctions of things which go to the heir and to the executors respectively. The distinction corresponds to a certain extent to the phrase 'Heir and Exceutor' (q.v.) in England.

HERITABLE BOND, in Scotch Law, is a bond for a sum of money, and joined with it a conveyance of land in security thereof. The usual deed is now a bond and disposition in security, corresponding to the English mortgage (q.v.).

HERITABLE JURISDICTIONS, a remarkable class of jurisdictions held hereditarily from the creation of the office and abolished (1748) by 20 Geo. III. c. 43. These jurisdictions amounted to upwards of a hundred in number, and consisted of sheriffships, stannaries, constabulary, but principally of regularities and bailiwick, with some offices of distinction. One of the most important was the office of Lord Justice-General, and the lordship of Argyile and the Isles, both belonging to the family of Argyile. In virtue of their hereditary rights, the possessors of these jurisdictions exercised an arbitrary power over vassals and others within the limits of their domain, and could punish them by fines, scourgings, imprisonment, and even in some cases put them to death, without interference of the common law. As representing a feudal and arbitrary policy, and not calculated with the view of extinguishing the authority of Highland chiefs over their clans, these heritable jurisdictions were abolished; the possessors receiving payment for the assumed value of their rights. Argyile, alone, received £21,000 as an indemnity, and altogether there was paid by government £152,037, 12s. 2d. The abolition of these obnoxious jurisdictions being followed by the appointment of sheriffs on a proper footing, this great legislative act marks an important era in the history of Scotland.

HERITABLE SECURITIES, the name given in the law of Scotland to what are called mortgages and charges on land in England. These were formerly distinguished into wadset, infetment of annual rent, heritable bond, bond and disposition in security, and absolute disposition with back-bond, and also reserved burdens on land. All heritable securities are founded on the theory, that they constitute a pledge of the land to the creditor until the debt is discharged, and that the debt is a burden on the land, so that whatever becomes of the land, into whatever number of hands it is conveyed and transferred, the debt still inheres in it, and must be first paid out of the proceeds, unless it is redeemed. In England, the principal heritable security is called the bond and disposition in security, which consists of an obligation to pay the debt, and a disposition pro tempore to the creditor, by way of security till the debt is paid. The bond must be registered in the Register of Sasines, to complete the title, and it is assignable to a third party. A power is always given to the creditor to sell the estate, if the principal or interest is not paid, in which case, the creditor must account for the surplus after paying himself his debt.

HERITOR, in the Law of Scotland, is the owner of land in a parish liable to public burdens. The heritors, collectively, have vested in them the fee of the church and churcheyard; they elect the parish schoolmaster, repair the parish church, &c.

HEM.E. See HERM.

HERMANDAD, The (Sp. 'Brotherhood'), an association of the principal cities of Castile and Aragon, bound together by a solemn league and covenant for the defence of their liberties in seasons of trouble. These confederacies were sanctioned by the sovereigns, as agents for suppressing the increasing power of the nobles, and for maintaining
public security through the land with no cost to the people. In Aragon, the first Hermann was established in the middle of the 13th c., and in Castile about 30 years later; while in 1295, 35 cities of Castile and Leon formed a joint confederacy and entered into a compact, by which they pledged themselves to take summary vengeance on every noble who had either robbed or injured a member of their association, and refused to make just atonement for the wrong; and although the laws, in an attempt, even by the order of the king, to levy an unjust tax. During the long period of anarchy in which the Christian rulers of Spain were impotent to maintain order in their own dominions, the Counts Hermank, and under Isabella of Castile, saw the beneficial effects which an extension of the jurisdiction was of producing, obtained the sanction of the Cortes for its wars and policies, and extension over the whole kingdom in 1496. The crimes reserved for its jurisdiction were all acts of violence and theft committed on the highways or in open country, and the penalties attached to such misdemeanour were specified with the greatest precision in the codes of laws, which were enacted at different times in the yearly assemblies of the deputies of the confederate cities. An annual contribution was, moreover, assessed on every hundred householakers or sevino, for the equipment and maintenance of the horsemen and quadririo or officials of the brotherhood, whose duty it was to arrest offenders, and enforce the sentence of the Cortes. The laws of the Hermans, regarded with much disfavour by the aristocracy, continued for many years to exercise its functions, until the country was cleared of banditti, and the ministers of justice enabled to discharge their duties without great disturbance of the peace. In 1498, the objects of the Hermans having been obtained, and public order established on a firm basis, the brotherhood was dissolved, and reduced to an ordinary police, such as it has existed, with various modifications of form, to the present century. The laws enacted at different times in the juntas or assemblies of the Hermans were compiled, in 1495, into a code, known as the Quadernos de los Leyes, and issued by the Hermans, which was first printed at Burgos in 1527.—See Mariana, History of Spain; Pulgar, Reyes Catolicos; Prescott, History of Ferdinand and Isabella.

HERMANN, JANN Gottfried Jacob, a German philologist of great genius and learning, was born at Leipzig, 28th November 1772; studied there, and at Jena, and was made, in 1798, extraordinary professor of philosophy. In 1803, he was called to Kiel as ordinary professor of eloquence, becoming in addition professor of poetry in 1809, and in this position he remained till his death, 31st December 1848. Distinguished by liberal-mindedness and love of truth, by eloquence and extensive culture, he endeavoured till his latest days to attract a large circle of students to his class-room, which sent forth some of the most celebrated teachers in the schools and universities of Germany. The first department which he began to cultivate on original principles was that of history, to which he attempted to develop a philosophical theory from the categories of Kant; and on this subject he wrote, besides his Handbuch d. Metrik (1794), several Latin treatises, among which his Ueberliche Doctrine Metrik (1818) reached a third edition in 1852. Of wider importance, however, was the new method which he introduced into the treatment of Greek grammar, which has had its influence on the grammar of Latin, and even of modern languages, especially of the German. The principles of this method are not only explicitly developed in his De Einemendia Ratione Graecae Grammaticae (1818), but are practically illustrated in his numerous editions of the ancients. The power of dealing with chronological, topographical, and personal questions, is shewn in his Ossia (7 vols., Leip. 1827—1830), which also contain some poems breathing the spirit of Roman poetry. Consult Jahn's Gottfried H. eine Gedrichsamme (Leip. 1849).

HERMANN, or HERMAN, a name that first appears in Germany in the 6th c. after Christ, but is now become common. It has been erroneously transferred to that prince or chief of the Cherusci, called by Roman writers Arminius, and by the Greeks Armenios. This personage was the son of Sigimer, and was born 16 A.D. The period in which the youth of this Hermann was brought with the greatest peril to Germany. To secure the frontiers of the empire against the attacks of the Germanic tribes, the Romans had been forced to advance into the more turbulent districts, and to build a series of forts to overawe the inhabitants; in this manner, not only had most of the Celtic tribes from the Alps to the Danube been subdued, but in the years from 9 A.D. to 4 A.D., Drusus and Tiberius had penetrated into the north-west of Germany as far as the Elbe, laid the roads of military roads, erected fortresses in the country, and reduced the different tribes to such dependence upon Rome, as virtually amounted to complete subjugation. With so much prudence and caution had Tiberius proceeded, that the name of Hermann remained in all appearance on the best terms with the Romans, gradually adopted Roman habits, and frequently and readily took service in the Roman armies. Thus H. and his brother Flavins had enrolled themselves under the Roman standards, and as leaders of Cheruscan auxiliaries, had not only obtained Roman citizenship and the rank of knighthood in the country of the Danube, but had likewise acquired a knowledge of the Latin language, and a deep insight into the arts of war and policy as practised by the Romans. Enriched with these experiences, when H. after the expiration of some years, returned home, he found the state of affairs considerably changed for the worse. Through the unskillful despotism of the Roman viceroy, Quintullus Varus, H. now conceived the plan of delivering his country from its oppressors. All the tribes and leaders as far as the Elbe were secretly summoned; Varus was lulled into security, and induced to despatch portions of his army to different points, and with the remaining portion, which was just on the point of leaving the country of the Cherusci for the Rhine, to quit the highway. He was thus lured into the impassable districts of the Teutoburg Forest (either in the upper valley of the Lippe, or the adjoining Prussian territory); an engagement took place, which lasted for three days. The result was the annihilation of the whole Roman army (9 A.D.). When intelligence of this defeat reached Rome, it excited the greatest consternation and anxiety. The Germans, however, who had only their own liberation in view, prosecuted their victory no further; and for a few years littéraly changed for the worse. To speak, hung fire. When Germanicus (q.v.), however (14 A.D.), assumed the command on the Lower Rhine, he resolved to crush the barbarians. In two successive campaigns, 14 A.D. and 16 A.D., he reduced H. to great straits; but he being recalled to Rome by the Emperor Tiberius, 17 A.D., the results of his victorious activity were lost. From this time no Roman army ever ventured to penetrate
from the Rhine into the interior of Germany, and this circumstance, which decided the future fate
of Germany, must be ascribed chiefly to Hermann.

Nevertheless, no sooner was the foreign enemy
expelled, than the internal feuds broke out, and
more violence than ever. In the course of these, H.
was slain by his own relatives, in the 37th year of
his age and twelfth of his leadership.Tacitus says
of him: 'He was, without doubt, the deliverer of
Germany and unlike other kings, he attacked
the Roman people, not at the commencement,
but in the fulness of their power; in battles,
he was not always successful, but he was invincible
in war. He still lives in the songs of the barbarians,
though unknown to the annals of the Greeks, who
admire only what belongs to themselves; by the
Romans, he is not estimated according to his merits,
because in our admiration for the past, we neglect
the present.'—Compare Wiederheim, Der Feldzug
der Germanen an der Weser 16 v. Chr. (Leip. 1850);
Massmann, Arminius, Cheruscorum Duc ac Decus,
Liberator Germanorum (Lunigo, 1839).

HELMANNSTADT (Lat. Cambium, Hung.
Nagy-Szeben), an important town of Austria, capital
of the county of Transylvania, is beautifully
situated on the Cibin, or Zibin, an affluent of the
Alta, about 70 miles west-north-west of the
town of Cronsdalt. H. is the seat of the Austrian
governor of Transylvania, and of a Greek non-
united bishop, and is the head-quarters of the 12th
corp of the imperial army. Pleasing promenades
surround the town, and the district in which it
is placed is fertile as well as beautiful. Tan-
ning, wax-bleaching, and the manufacture of cloth
(linen and woolen), combs, paper, and gunpowder,
chiefly employ the inhabitants. The local trade
is considerable. Pop. 18,600, one-half of whom are
Protestants.

H., originally a village, is called, on the ancient
seal of the town, Villa Hermani. The Hermans
from whom the town has its name was a citizen of
Nurnberg, and is said to have led his colony in
the 12th century.

HERMAPHRODITE, in Botany, the term
employed to designate those flowers which contain
both the stamens and female organs of reproduction
(stamens and pistils), and are therefore by them-
elves capable of producing perfect seed. Flowers
containing only male or female organs are called
unisexual or unisexual (q.v.), and are produced on
the stems only, Monocotyledons (q.v.) when on different
plants, Dioecious (q.v.). Hermaphrodite flowers are
also called monochonas (Gr. monos, one, and klinê,
a couch) and perfect flowers.

HERMAPHRODITISM is the term employed
by naturalists to designate the state or condition of
those organisms, whether animal or vegetable, in
which the characteristics of the male and
female are united in the same individual. The
name is derived from the fable of the union into
one of the bodies of Hermaphroditus, son of Hermes
and Aphrodite, and the nymph Salmacis. See Ovid's
Metamorphoses, lib. iv. v. 347.

There are two kinds of hermaphroditism, the
true and the spurious; in the former, there is an
actual coalescence of the same individual, of male
and female reproductive organs; while in the latter,
there is only an appearance, from arrest or excess
of development, of a union of the distinctive organs
of both sexes. True hermaphroditism is the normal
type of sexual structure in most plants. See
Hermaphroditism, in Botany. It likewise occurs
normally in many of the lower invertebrata, and as
a monstrosity in the higher invertebrata, and even
occasionally in certain vertebrata.

The recent investigations of Balbiani show that
certain Infusoria (as, for instance, the common green
Paramoecium), at all events occasionally present
the phenomena of hermaphroditism. In some of the
polye (as, for example, the Hydra and some of the
Actinidae), the sexes are united in the same indi-
dividual; the same is the case with some of the Acetabulae
(namely, the Centropora), with certain orders of
Helminthes or parasitic worms (for instance, certain Annelides (the Hirudines
and Lumbrii), of which the bee and the earth-
worm are typical examples), with many acelphalous
molluscs, with the Pteropods and with most of the
Gastell spoa; while in the other classes of molluscs,
the Cephalopods, the sexes are always distinct.
Among the crustaceans, the Cirripedia are for the
most part hermaphrodites; but in the other and
higher orders, if hermaphroditism exists, it is only
as an abnormal occurrence, and gives rise to a
monstrosity. (For example, the common lobster
has been observed with male organs on one side of its
body, and female organs on the other.) True but
not normal hermaphroditism is also occasionally met
in cases of some of the higher land-animals. In fourteen cases
among the she-bear, the right side was male, and the left female;
and in nine cases it was the reverse. Professor
Owen remarks that in insects hermaphrodites are
occasionally found, where the characters of one sex,
instead of extending over one-half, are limited to
particular parts of the body which agree in the
main with the other sex. Thus, in an individual of
Gastrophthalmus quercus, the body, the antennae,
and wings were those of the male, while the
right wings were those of the male.

True (but of course abnormal) hermaphroditism
is far rarer amongst the vertebrata than in insects
or crustaceans. Various instances, however, are
on record, a presenting a lateral imperfect
structure, or a re on one side and a milt on the
other; and references to various cases that have
been reported may be found in Professor Simpson's
learned and elaborate article, 'Hermaphroditism,' in
The Encyclopaedia of Anatomy and Physiology. The
same article may be referred to for cases of similar
hermaphroditism in birds and mammals, including
the human subject, namely, cases in which there
are female structures on one side, and male struc-
tures (more or less perfect) on the other.

Returning from these cases of abnormal true
hermaphroditism to those of normal true hermaph-
roditism, the question naturally suggests itself.—'Are
the male and female organs, fertilising themselves?
As far as is known, none of the terrestrial hermaphroditae, such
as land-molluscs (the common snail, for example)
and earth-worms, are self-impregnating. They all
pair, and in this respect offer a strong contrast
with hermaphroditae plants. But of aquatic animals,
there are many self-fertilising hermaphroditae.

For further details on the subject of hermaphroditism
generally, the reader is referred to Steenstrup's
Ueber die Vorkommen des Hermaphroditismus in der Natur
' (1846).

Spurious hermaphroditism is a subject of too
purely a professional character to be noticed at all
fully in these pages. Those who take an interest
in this subject may be referred for further infor-
mation to Professor Simpson's article, and to a case
recorded about two years ago in The Lancet by Dr.
Girdwood.

HERMAS, the name of one of those who were
members of the Roman Church at the time at which
St Paul wrote his Epistle to the Romans, and, as
may be inferred from the apostle's addressing a
special greeting to him, a person of some eminence
among his fellow-Christians. He was though
HERMENEUTICS—HERMES.

resident at Rome, most probably, judging from his name, of Greek origin. H., however, has obtained even more consideration from the circumstance of his being the reputed author of the well-known early treatise, called *The Shepherd*, which is commonly classed among the writings of the apostolic Fathers. It is ascribed to the H. of St Paul, more or less positively, by Origen, Eusebius, and St Jerome. But there is a second H., who lived about the time of the church, as converted in the midst of the dogmatical definitions of pontiffs accepted by the universal church. From this circumstance, it is often inferred that in the Roman Catholic Church the science of hermeneutics is a nullity, and that no freedom of interpretation is practically permitted.

The Roman Catholic critic, however, maintains that he exercises, and is free to exercise, on the text of Scripture the same liberty of interpretation which the Protestant may claim; and that it is quite possible that he may arrive at precisely the same conclusions with the Protestant as to the meaning of the *scriptural text* considered in itself alone. But he differs from the Protestant in believing that the Scripture does not contain the revelation, and, therefore, that, as one passage of Scripture is modified by another, so the scriptural revelation itself may be modified by other revelations of God conveyed to us through other mediums, and not of tradition. As regards the literature of Hermeneutics, most of the writers named in the article EXEGESIS have dealt with both branches of the science. They are for the most part Protestant. The most remarkable modern Catholic hermeneutical writers are; Hermann Goldbagen (Mainz, 1765); Scemmiller's *Hermeneutica Sacra* (1779); Mayr's *Institutum Justap. Sacri* (1789); Johann Euchirichus Hermes, (Vienna, 1812); Angler's *Hermeneutica Generalis* (1813); Unterkircher's *Hermeneutica Biblica* (1831); Ranold, *Herm. Bibl. Principia Rationalia* (Fünf Kirchen, 1828); Schnittler, *Grundzüge der Hermeneutik* (Katisbon, 1844); Claire's *Hermeneutica Sacra* (1846).

HERMES, the name of a divinity more familiarly known as Mercury, the god of speech, eloquence, the sciences, traffic, theft, and herds. Under his name are comprised several mythological personages, who personified the extent of mankind's thought, whether human or divine. The principal of these are Teti, Thoth, Theoth, or Taut, the Egyptian H., the Greek god properly so called, the Phoenician Taat, the Carthaginian Sames, the Etruscan Tver, the Chaldean Istar, and the Latin Mercuis. The oldest of these was undoubtedly the Egyptian, whose worship appears as early as the 11th dynasty. Thoth was generally represented with the head of an ibis (ibis), which was his living emblem, and expressed his name in hieroglyphs. These, according to the legends, he had invented and revealed to the monarch Thamus. Many religious books were believed to have been written by him, and all literary compositions were dedicated to him. He was scribe or clerk of the gods, and in the future state justified the good against their accusers, as he formerly had Osiris in the trial of that god and Typhon. In the contest between Typhon and Osiris, Thoth had torn off the diadem of his mother Isis. Thoth is reported to have replaced it with the head of a cow. Locally, he was lord of Sesmem, Hermopolis, the modern Esphumun, but his worship was universal. He was a self-created, self-existent god, although some legends of later date make him the son of Chnumis, or of the Nile. In his celestial character he was identified with the moon, Aah, and was supposed to preside over that luminary.
HERMES—HERMETIC BOOKS.

and the souls which made it their habitation. He inscribed also the names of monarchs on the ostra or Peraea, the tree of life of the Egyptian paradise.

In the Phoenician mythology, Taaut or H. seems derived from the Egyptian, and he was the son of Min or Egypt, inventor of writing and the sciences; while the name of himself, or his name as Hermes, is that of one of the Punic H. of Carthage. It is, however, clear that the name Taaut is derived from the Egyptian Tet, ‘word’ or ‘speech.’ The tradition of H. has passed to the Arabs, who recognize two Hermes, one who lived 1000 years after Adam, called by the Chaldeans Orliai or Duvani, the great master; another, surnamed Thani, doctor of the world, and liberator of men from error, a prophet and philosopher; and Trismegist, the three-great, who lived at Calovax, in Chaldaea.

But the most important of all was the Greek Hermes. The various traditions which make him the son of the Egyptian Nius, whose name was never pronounced, or the sacred Thoth, are clearly Egyptian, that which derives his origin from Ouranos, and Hemera, is probably the Phoenician myth. But the principal H. in whom the actions of the others centered, was the son of Zeus and Maia, born on Mount Cyllene, in Arcadia, and originally of Phoenician origin, overspread over cattle and commerce. His birth is placed subsequent to that of Apollo. Four hours after, according to the hymn, he left his cradle, and his mother, Maia, who not only had preserved the secret of the secrets, but also created the lyre, using its shell as a sounding-board, and making the strings out of the entrails of a sheep. At nightfall he stole fifty of the sacred herds of Apollo from Pieria, drove them to the banks of the Alpheus, slaughtered and dressed two of them. To escape detection, he had bound his feet with branches of the myrtle and tamarisk. Apollo, missing his cattle, dragged H. before Zeus, at Olympus, who condemned him to restore them; but Apollo, enchanted by the sound of the newly invented lyre, offered H. his cattle in exchange, gave him his whip or goad, taught him how to tend cattle, and presented him with the caduceus. In the Iliad and Odyssey are no traces of his talisman, which were first accredited to him by the later poets. In the Gigantomachia he liberated Zeus from Typhon, and restored him his limbs. H. was messenger, herald, and ambassador of the gods; he bound Prometheus to Caucasus, killed Alcyoneus, and a hundred other heroes; he crossed the sounding Io, &c. In the events of the Trojan war, he conducted the goddesses to the fatal judgment of Paris, brought Priam to Achilles, and was patron of Ulysses to whom he gave the herb melos, to liberate him from Circe. Many heroic and other personages were descended from him. As god of the sciences, he invented the alphabet from the flight of cranes, astronomy, and numbers, weights and measures, music, the lyre, and syrinx, gymnastics, tactics, and the cultivation of the olive. Many festivals were celebrated to him in Northern Greece and the islands, as at Pheneus, Cyllene, and Athens; and some of these Hermaea resembled the Saturnalia, and were celebrated on those occasions by their masters. His worship, in fact, extended all over the Peloponnese, the islands of the _Egean_, Asia Minor, and even Heropia or Magna Grecia. Amongst animals, the tortoise, pig, lamb, goat, and the young of beasts, were sacred to him; the ibis and the gull (larus) amongst birds; and the palm-tree, black-thorn, cinquefoil, and purslane amongst plants. H. had a local worship in Samothrace, where he appeared as one of the Cabi, under the name of Cosmas, the son of Hephasteus or Vulcan, and Cabira. In the Eleusinian mysteries, he was represented by the hierocery. The idea of H. seems to have been developed from his origin—the ancient Pelasgic or Arcadian god of shepherds, subsequently considered the patron of barter, of commerce, without any trace of intellectual qualities; and the Phoenician Tet or the name of the god of commerce of Greece, with all the attributes attributed by the Orientals to their deity. In art, a similar development is seen from the old squared trunks or pillars, called Hermes and Heraudia, retained till a later period, but by degrees ornamented with a bearded head, to which sometimes are added phallic symbols, the destruction of which at Athens before the sailing of the Sicilian expedition led to a fearful tumult, and the fall of Alcibiades (q.v.). In later, but still archaic art, he is represented bearded, wearing the broad-brimmed pæsos, and holding the twisted caduceus. At the time of Phidias, he was represented unbearded, with curly hair, a crafty and charming expression, and the form of an athlete. Instead of the pæsos, wings are sometimes arranged in his hair; his boots are winged, and his caduceus has two snakes attached to it. His form is naked, but often has a chlamys, or cloak, doubled about his neck, upon which is a purse of money; while the cock, referring to his invention of the gymnasion, or the hours of business, the tortoise, allusive of his discovery of the lyre; the palm-tree, emblem of his invention of letters; the goat, emblematic of his introduction of the cymbals; and the pan; and even the dog, by all him with Amnis, are placed at his side. The most remarkable type of the god was as carrying a ram upon his shoulders (criophorus). The caduceus was gilded at the top, painted blue in the middle, and black at the handle.

The Etruscans seem to have derived his worship directly from the Greeks, and represent him with the same attributes and type, but with the Etruscan name _Tuane_, or the Caduceus of the gods. His worship passed into Rome, under the name of Mercureius, or Mercury, by which he is more familiarly known, supposed to be derived from mercari, to traffic. There was something mystic in his cult, for it is said that the seer of Amnis, who originally had the laurel instead of the caduceus, and the name of his mother Maia had been given to the mount Mains, or May, on the 15th day of March, whom the Druids associated with the 239 A.C.T.C., he had a temple near the Circus Maximus, and his statue in that locality held a purse. At the Porta Capena, there was a well sacred to him, and the merchants sprinkled themselves and their goods with the holy water, obtained by dipping a laurel branch into the well. Tradition makes him the father of Evander by the nymph Carmenta, and of Larea by the goddess Lara; but the Romans adopted into their religious system the Greek traditions, although, at a later time, under the empire, the influx of foreign religions made them confound him with the Egyptian Anubis, and even represent him with a dog's or jackal's head, and depict him of a golden or black colour. His worship had even extended to Gaul, where he was adored under the name of Teutates.—Griber, _Atlistas_. _Worterbuch Vose_; Gerhard, _Griechisch Mythol._ (Svo Berl. 1854, i. 256); Hartung, _Rel. d. Romer_ (Svo Frb. 1843); Birch, _Gott. Atske_, pp. 20, 27; Muller, _Arch. d. Kuns_, p. 500.

HERMETIC BOOKS. Amongst the Egyptians, all books or literary compositions appear to have been dedicated to Hoth, and notices of this nature are appended to several papyri. The earlier religious books, such as the Ritual, were supposed to have
HERMIT—HERMIT CRAB.

been written by the fingers or under the dictation of the god Thoth himself, and several chapters of the other works are stated to have been found on monuments written by the god. Hence the word hermetic, taken in its most extended sense, means inspired, as Thoth was the scribe of the gods. Various traditions prevailed as to the number and nature of these books. Element of Alexandria mentions 42 hermetic books, which contained the secrets of all knowledge; while others, as lamblichus, raise their number to 20,009; and Manetho gives the astronomical cipher of 36,325. The series of books mentioned by the great authors were: 1. Sacred hymns of Osiris; 2. On the Life of a King; 3—6. Astrological precepts and observations; 7—17. Cosmography, geography, and chorography of Egypt and the Nile; 18—27. Laws, and discipline of priests; 28—33. Medicine. Portions of these books have been undoubtedly found in the hieratic papyri. Under the name of hermetic books, several writings, principally in Greek, have been handed down, which pretend to be translated from the Egyptian, and similar books may have existed in the century. But the various notions of the Neo-Platonic school of Porphyry and lamblichus, and appear to be intended as philosophical works giving an explanation of the genesis of the Cosmos, the nature of God and man, in antithesis to the books of the Old and New Testament, from sources partly Egyptian, partly Persian and Babylonian, and other traditions of the Alexandrian school. The name of hermetic writings was particularly affected by the alchemists and astrologers of the middle ages, as the Tractatus de Aurore, by dominicus gnostus, in 1610; the Tabula Smaragdina, or 'Emerald Table of Alchemy,' in 1541; and various others. The principal tenets of the hermetic books, as the Creator made the Cosmos by his word out of fluid; that the soul is a union of light and life, and proceeded from the cosmic soul; that death and life are only changes, and that nothing is destructible; that the soul transmigrates; that passion or suffering is the result of motion.—Bauergarten-Cruzins, de Librovm Hermelorum Indole (Jena, 1827); Hermais Transigmatis, a Scheible (12mo, Stuttg, 1855); Hermes Transigmatis (Foemander) a Parthey (8vo, Berol, 1834).

HERMIT (Gr. eremitos, Lat. eremita, an inhabitant of the desert), one of the names given in the early ages, and still more in the later church, to a class of solitary ascetics, who, with a view to more complete freedom from the cares, temptations, and business of the world, withdrew from the ordinary intercourse of life, and took up their abode in natural caverns or rudely formed huts in deserts, forests, mountains, and other solitary places. In the first centuries, the names of eremite and anchorite (q. v.) were indiscriminately applied to these solitary; but the word eremitos having been adopted into Latin, it is more commonly used in the modern languages which are derived from the Latin; and the Germanic name, Einzeller, which is of the same signification. The hermits of the middle ages, like the primitive anchorites, often lived in complete solitude; but a more exact common, and, in its influence on the church, more important form of the institute, was that of a community of hermits, each possessing his separate hermitage, but all meeting at stated times for mass, prayer, religious instruction, and other common and public exercises. The various hermits of this class are regarded as constituting religious orders, and although never attaining to the popularity which distinguished the Franciscans, the Capuchins, the Dominicans, and other active orders, they form, nevertheless, a numerous and not unimportant element in the spiritual life of the Roman Catholic Church. It is beyond the scope of this work to enumerate all the eremitical orders. The most remarkable are—the hermits of St Augustine, who trace their origin to the holy father of that name, but are subdivided into several varieties, which had their rise in the 11th, 12th, and 13th centuries; the Cauvalthilose, founded by St Romuald in 1012; the Celestines, a branch of the Franciscans, established by Peter Murrene, afterwards Pope Celestine V.; the Hieronymites (q. v.), established first in Castile in the 14th c., and thence introduced into other parts of Spain and into Italy by Lope d'Olmedo in 1424; and the Paulites, so called from St Paul, the first hermit, but an institute of the 13th c., which had its origin in Hungary, and attained to a wider extension and a greater popularity than perhaps any other among the eremitical orders. See Helvét, Histoire des Ordres Religieux; also Weister, Kirchen Lexicon, art. Einzeller.

HERMIT CRAB, the common appellation of a large family (Paguride) of crustaceans, of the order Decapoda, and sub-order Anomura (see Crab), having the abdominal or tail segments much more largely developed than in true crabs, but undefended by hard plates, and not forming an organ for swimming, as in lobsters, prawns, and other Malacoa. The soft and tender tail requires a protective covering, which the instinct of the hermit crab leads them to find in some turbinated univalve shell of suitable size. The most common British species (Pagurus Bernardus) is an interesting object to every visitor of the sea-shore, and may be found in abundance wherever little pools are left by the tide on a rocky or shelving coast. Shells of whelks, periwinkles, &c., may be seen moving about in the pools in a manner very different from that in which they were carried by their original mollusaceous owners, having now become the property and habitations of hermit crabs, by which, perhaps, the molluses were eaten. On the slightest alarm, the H. C. retires into the shell, guarding the aperture of it with one claw, which is much larger than the other, the hard points of the foot also projecting a little. The whole structure of the animal is adapted to such a habitation. The part which in the lobster becomes a finlike expansion at the end of the tail, becomes in the H. C. an appendage for firmly holding by the shell; and so firmly the

Hermit Crab (Pagurus Bernardus):

a, animal out of the shell; b, in shell; e, a jaw-foot.
HERITAGE—HERNIA.

H. C. hold, that it may be pulled in pieces, but cannot be pulled out. Some species have stouter to make the hold more perfect. Increase of size, however, renders it necessary for hermit crabs to relinquish their old shells and seek new ones. Hermit crabs are very interesting inmates of the aquarium, and by their hermit-like habits and timidity make them unsuitable for an aquarium otherwise very finely stocked. They feed on mollusces, and on all the animal garbage of the sea-shore. Some of the hermit crabs of warmer climates are much larger than the British species; some of them (genus Corolla) inhabit land-shells, and some are found even at a distance from the sea.

HERMITY, the cell or hut of a single hermit, and sometimes the aggregate of the cells occupied by the members of a single community. Many of these, from the reputation of their inmates, or as being the scenes of certain popular miraculous legends, attained great celebrity, and became the nuclei of important ecclesiastical establishments, and, in some instances, large and populous cities.

HERMODEACTYL (Gr. Hermes, Mercury, and dactyl, a finger) is the name of a medicine that had a high repute among the later Greek and the Arabian physicians, as a remedy for gout and rheumatism. It is mentioned by Alexander of Tralles, who flourished 300 A.D.; Paulus Aegineta, who lived a century later; Avicenna, Serapion, &c. By some of the old writers, it was termed anima articulorum, or the soul of the joints. Corns, probably of several species of colchicum, are still sold in Greece and in the East under the name of hermodactyl. While Sir H. Halford and others have advocated the view that hermodactyls are the corons of Colchicum autumnale, different botanists and pharmacologists have referred them to C. illyricum, C. tardigradum, C. bulbocodiodes, &c. No modern experiments have been made to determine the activity of hermodactyl, and the subject is one rather of historical than of practical interest.

HERNIA, in its widest sense, signifies a protrusion, through an abnormal or accidental opening of any organ from its natural cavity. Although hernia may occur in many parts of the body, the wound, used by itself, is restricted to signify protrusion of the abdominal viscera. In the same way in which hernia may arise will be readily understood, if we bear in mind that the abdominal viscera are subject to violent pressure from the diaphragm and other surrounding muscles. This pressure forces them outwards and downwards against the walls of the belly; and if at any point these walls are not sufficiently strong to resist this pressure, some portion of the viscera is driven through them, and a hernial tumour is formed. Certain parts of the abdominal walls, especially the inguinal and crural rings, and the umbilicus, being weaker than others, hernia most frequently occurs at these points. In some instances hernia is congenital, as from abnormal deficiency of the walls; in other cases, it may arise at any period of life as a result of violent bodily exertion. Sex, age, and occupation seem to have a marked influence in predisposing to hernia. Men are far more liable (in about the proportion of four to one) to this disease than women; though they are less subject to those forms which are the result of the affection known as femoral and umbilical hernia. According to Malagaine, in France, one man in thirteen, and one woman in fifty-two, are the subjects of hernia. In respect of age, he found that in infancy hernia is least about the age of three years (1 in 77), after which it progressively increases until the close of life, rising at 70 to 75 to 1 in 3.

A hernia is almost always composed of a sac and its contents. The sac is a portion of the Peritoneum (p. 42) that forms the envelope at which the hernia protrudes. It is pushed forward by the protruding visera, and forms a pouch. The contents vary greatly, but generally consist of a portion of the intestines; sometimes of a section of the omentum, forming the variety of hernia known as omentocele. Omentum is often found in hernial sacs, together with intestine. Besides the visera, the sac always contains a certain quantity of fluid secreted by its interior. Hernia is divisible (1) into reducible, or returnable into the abdomen, irreducible, and strangulated; and (2) according to its situation, into inguinal, crural, &c.

The treatment of reducible hernia may be palliative or radical. The palliative treatment consists in the application of a Truss (q. v.) to retain the protrusion within the cavity of the abdomen. Each particular kind of hernia (femoral, crural, &c.) requires its special form of truss; and before applying it, the hernia should be reduced by placing the patient on his back, relaxing the muscles by bending the thigh upon the abdomen, and pressing the tumour back in the proper direction. The truss should then be put on as soon as the patient is out of bed, and if the patient will submit to wear it (or a higher one) during the night, so much the better. The means that have been contrived to effect a radical cure are too purely surgical for description in these pages. Below the age of puberty, or if the hernia is recent, a radical cure is sometimes effected by wearing the truss for two or three years.

In irreducible hernia the protruded visera cannot be returned into the abdomen, but there is no injurious effect from their passage of their contents or their circulation. In these cases, the patient is often liable to dragging pains in the abdomen, and to attacks of vomiting, in consequence of the movements of the stomach being checked by the omentum. In these cases, the patient should be kept in the recumbent position, and on very low diet, for two or three months, while, at the same time, keeping the opening open by laxatives and injections, and maintaining equable pressure over the tumour.

Hernia is said to be strangulated when a portion of intestine or omentum that is protruded is so tightly constricted that it not only cannot be returned into the abdomen, but has its circulation arrested. This form is highly dangerous, because, if relief is not speedily afforded, the strangulated part becomes gangrenous. The causes of strangulation are various, but this condition most commonly arises from a sudden violent effort, by which a fresh portion of intestine is driven into a pre-existing hernia, which it distends to such a degree as to produce this complication. The most prominent early symptoms are flatulence, colicky pains, &c. They are succeeded by vomiting first of the contents of the stomach, then of mucus and bile, and lastly of fecal matters, owing to inverted peristaltic movements, and having a bloody nature. The stricture that commences in the sac extends to the peritoneum, and the ordinary signs of peritonitis appear. After a variable time, comes gangrene or mortification of the part, and the patient speedily sinks.

The surgeon first tries to return the tumour, as in the preceding cases. This manipulation, termed the tazia, may be assiduously the internal use of
HERO—HERODOTUS.

chloredom, inhaled till it produces complete relaxation of the muscle, by general bleeding to the extremities from the maxillary, &c. Besides it, he must have recourse to the knife to divide the constriction.

HERO, a priestess of Venus, celebrated for her love for Leander. At a festival of Venus and Adonis, held at Sestos on the Thracian coast, H. and Leander last saw each other, and were immedia-
tely inspired with a mutual passion. H.'s position as a priestess, and the will of her parents, opposed their union. Undaunted by these obstacles, Leander every night swam across the Hellespont to meet his beloved, who directed his course by holding a burning torch from the top of a tower on the sea-shore. After many interviews, Leander was drowned in a tempestuous night, and was cast on shore at the foot of the tower, where H. anxiously awaited him. At the sight of the body, she threw herself from the tower. A poem has come down to us under the name of Musaeus, in which this story is sung; Schiller likewise has made it the subject of a beautiful ballad.

HERO, or HERON, commonly known as HERO of ALEXANDRIA, was a pupil of Ctesibius, and flourished 284—221 B.C. He was a celebrated mathematician and natural philosopher, and displayed, especially in the latter subject, a most original and inventive genius. He constructed the most remarkable number of machines and automata—rather, however, as toys, than for the purpose of applying them to any useful purpose—among which are Hero's Fountain (q. v.); a steam-engine on the principle of Basker's mill (a vessel being caused to revolve by jets of steam issuing from lateral holes in the arms with which it is provided); a double forcing-pump used for a Fire-engine (q. v.), and various other similar applications of air and steam. It is but recently that the remarkable claims of H. to such discoveries have received any notice, for, in the valuable work of M. Dutens, entitled L'Origine des Découvertes attribuées aux Modernes, the name of H. is not even mentioned. Among his works which have come down to us are Pneumatiika, his most valuable work, in which the above-mentioned machines and many others are figured and described; helopneustika (on the manufacture of darts), and Chorehodithes (autodiakonia, on the construction of automata). All these works are merely fragments, and in acquaintance with them causes us to regard with the greater regret the loss of the rest. The best edition of his works is that published by the Société Mathématique et Physique de Paris (1839).

HEROD, the name of a family which rose to power in Judea during the period which immediately preceded the complete destruction of the Jewish nationality. The family was of Idumean descent; but, though alien in blood, was Jewish in religion, the Idumeans having been conquered and converted to Judaism by John Hyrcanus, 130 B.C. The most remarkable rulers of the name are four in number—Herod the Great, Herod Antipas, and Herod Agrippa I. and II. (for the two last, see AGrippa). 1. HEROD THE GREAT. He was the second son of Antipater, who was appointed procurator of Judea by Julius Caesar 47 B.C. At the time of his father's elevation, H., though only 15 years of age, was made governor of Galilee, and afterwards of Cæle-Syria; and finally, he and his elder brother were made joint-tetrarchs of Judea; but he was soon displaced by Antigonus, the younger brother. In the end, however, H. was forced to flee to Rome, where he obtained, through the patronage of Antony, a full recognition of his claims, together with the title of king of Judea, 40 B.C. Several years elapsed, however, before he succeeded in raising himself to the throne. On the fall of Antony, he managed to secure a good continue of favour from Augustus, from whom he not only obtained a confirmation of his title to the kingdom, but also a considerable accession of territory, 31 B.C. From this time till the end of his reign was undisturbed by foreign war; but it was stained with cruelties and atrocities of a character almost without parallel in history. Every member of the Asmonaean family, and even those of his own blood, fell in succession a sacrifice to his jealous fears; and in the latter years of his life, the lightest shade of suspicion sufficed as the ground for his wholesale butcheries, which are related in detail by Josephus. Of these, the one with which we are best acquainted is the slaughter of the infants at Bethlehem. The one eminent quality by which H. was distinguished, was his love of magnificence in architecture, and the grandeur of the public works executed under his direction. Even by these, however, he alienated the Jews, who ascribed them all to his Gentile leanings, and to a covert design of subverting the national religion. H. married no less than ten women, and had fourteen children. He died of a loathsome disease at the age of 70, after a reign of 37 years.

2. HEROD ANTIPAS, son of H. the Great, by his wife Malthace, a Samaritan, was originally designed by his father as his successor; but by the final arrangements of the will of H. the Great, Antipas was named tetrarch of Galilee and Perea. He divorced his first wife, the daughter of Aretas, king of Arabia Petrea, in order to marry Herodias, the wife of his brother Philip. Philip had deserted her in connection, against which John the Baptist remonstrated, and was in consequence put to death. It was during a visit of H. Antipas to Jerusalem for the purpose of celebrating the Passover, that our Lord, as having been a resident of his tetrarchate, was sent before him by Pilate for examination. At a later time, he made a journey to Rome, in the hope of obtaining the title of king; but he not only failed in this design, but, through the intrigues of H. Agrippa, was banished to Lugdunum (Lyon), where he died in exile.

HERODOTUS, the eldest Greek historian, and for this reason usually styled the 'Father of History,' was born at Halicarnassus, in Asia Minor, 490 B.C. He appears to have early formed the resolution of writing a historical work on an extensive scale, and, with this view determined to visit and observe with his own eyes the most remote countries and nations. Although the dates and extent of his travels are involved in obscurity, and sometimes even in contradictions in the ancient narratives, we gather from his own statements that in his early youth he visited the islands and coasts of Asia Minor; that subsequently he devoted particular attention to Egypt, which was at that time little known; that he next visited Palestine and Phœnicia; and finally penetrated as far east as Babylon and Susa. We are also informed that he sailed through the Hellespont into the Black Sea, and visited all the countries situated on its shores. After his return, he appears to have resided for a time at Athens. He speaks of having seen the Pyrgai, that is, the entrance to the passage which were not finished till the outbreak of the Peloponnesian war (431 B.C.). He also interested himself warmly in the politics of his native city, was instrumental in delivering it from the tyranny of Lycurgus, vassal of Persia; but being what we should call 'a moderate liberal,' he had the misfortune to offend the extreme or popular party,
and in consequence withdrew to Thurii, in Italy, where a number of his fellow-citizens had previously preceded. Here, in all probability, he wrote his immortal work in the decline of his life. Lucian, an indifferent authority on such a subject, states that about the year 450 B.C., he read the nine books before the Greeks assembled at the Olympic games, but this is contradicted by the numerous allusions in the History to incidents of later occurrence—for example, the revolt of the Medes against Darius (499–486 B.C.). The statement of Pliny, that it was composed in his old age at Thurii, is the most probable, and it best agrees with the unfinished programme of the work, and its abrupt termination, as if the author were prevented by death from finishing it as he intended. According to Suidas, he died and was buried at Thurii about 408 B.C.

The purpose of H. in his History is to describe the war between the Persians and the Greeks—the struggle for supremacy between Europe and Asia, between civilisation and barbarism, between freedom and despotism. H., wishing to indicate that the antipathy between the two was not the result of geographical or racial differences, or of a root difference of character, traces it back to the mythical ages. This was the only way in which a man in his time could express what we mean when we speak of the differences of race. In the course of his History, he gives an account of the various countries which he had visited. Wherever he gives the results of his own observations and inquiries, he exhibits a wonderful accuracy and impartiality; and where he does not do this, he is generally careful to say so. He has been accused of credulity, and it is certain that he too readily accepted statements on the authority of others, but that he was personally a keen intelligent observer of what he saw is beyond all dispute. H. wrote in the Ionic dialect, but Attic, Doric, or Eolic forms occur in his work. The style is marked by an easy grace and lively vigour, and everywhere there is the presence of a reverent spirit, giving a certain air of moral dignity to the entire composition. The first edition (in Latin), by Laurentius Valla, appeared at Venice in 1474; the first in the original Greek at Venice in 1502. The chief modern editions are those of Schweighauser (6 vols. Strasb. and Paris, 1846), G. Garin (4 vols. Oxford, 1841), Bühr (Leip., 1830–1834), and Müller (Paris, 1844). The best school editions are those of Matthiæ (2 vols. Leip. 1829), Bokker (Berlin, 1833 and 1845); G. Long (Lond. 1830), and Negris (Edin. 1834). A variety of translations into the writings of H. have likewise been published, as well as of historical and geographical treatises calculated to facilitate the study of the celebrated historian.

HEROES were, in the Homeric period, the kings, princes, generals, leaders, all brave warriors, and men who excelled in strength, courage, wisdom, and experience. Many of these had, on account of such qualities, a fabled origin, half human, half divine, and were honoured, after their death, with a hero cult, a deified men, or an equivalent. The heroes and demi-gods were recognised as the special patrons or protectors of particular countries and cities, and to them were raised temples and altars. These exalted ideas of heroic character, held up constantly to the admiration and imitation of peoples, tended to strengthen their peculiar character, and to impress them with the greatness and glory of courage, contempt of danger, and nobility of purpose. Poetry exalted the heroic sentiment to sublimity; and poems which celebrated the deeds of heroes, are themselves termed heroic. The imaginary time when heroes and other semi-divine beings lived on earth was called the Heroic Age. See Ages.

HEROIC VERSE. See METRE, VERSE.

HERON (Ardea), a genus of birds, of the order Grallatorei, tribe Culicirrostræ, and family Ardeaee. This family includes also Bitterna, Night Herons, Spoonbills, Boatbills, Storks, Adjutants, Ibises, &c. The bill is long, compressed, and sharp; the tail short; the legs and the toes long and slender; the wings long. In the herons—in which genus are included the species commonly designated Eoans (q. v.), which differ only in unimportant particulars of plumage—the bill is slender, but strong, forming a compressed and lengthened cone; the plumage is beautiful, but seldom exhibits very gay colours; white, brown, black, and slate colour, finely blended, being generally predominant. The body is small in proportion to the length of the neck and limbs; the neck is long, and, except in flight, is usually held curved. In flight, the H. carries the neck, head, and long bill in a straight line before the body, and the long legs in like manner stretched out behind. Heroes feed mostly on fish, frogs, and other aquatic animals; and may be seen, particularly in very early in the morning and late in the evening, standing motionless in some shallow water, at the margin of a lake or stream, or on the sea-shore, waiting till prey come within reach. In default of their more common food, however, herons sometimes prey on young birds, reptiles, and the smaller mammals. They usually go forth singly in quest of prey, but are mostly gregarious in their nidification. The Common H. (Ardea cinerea) is about three feet in length from the point of the bill to the end of the tail. It is of a delicate gray colour on the upper parts, except the quill-feathers, which are black, and the tail, which is deep slate colour. The Common H. generally builds its nest in a high tree, and many nests are sometimes to be seen in a single tree. Pennant tells us that he counted 80 in one oak in Lincolnshire. In very northern parts of the world, the H. is known only as a summer bird of-passage, but it remains in Britain all the year. Its geographical range extends over most parts of Europe and Asia, and includes the north of Africa. The H. was formerly in great esteem for the table, although now disregarded; it was also the kind of game most of all pursued in falconry; and the English act.

Common Heron (Ardea cinerea).
19 Henry VII. c. 11, prohibited the killing or taking of herons, except by hawking, or with the long-bow. This act was not repealed till the game act of Geo. IV. — The Purple H. (A. purpurea) is a smaller and much rarer British species.—The Great White H., or Great Eger (A. alba), a more ancient visitor of Britain and of the western parts of Europe, is more common in Turkey, Greece, &c., and in some parts of Asia. It is an extremely beautiful bird, with perfectly white plumage, much of its legs and flowing. — The Little Eger (A. parveta) has also white flowing plumage. It is only about two feet in length.—America has many species of H., most numerous in its warmer regions. The most common species in the temperate parts of North America is the Green H. (A. viridis), the flesh of which is so much esteemed that it is often to be seen in the markets.

Heron and egret plumes, made of the long feathers, were in former times highly valued, being, in some countries, deemed an ornament fit for royal personages, or for the highest nobles.

HEROPHILUS, one of the greatest physicians of antiquity, was born at Chalcedon, in Bithynia, and flourished in the 4th and 3rd centuries, B.C. He settled at Alexandria, and distinguished himself in particular by his devotion to anatomy. In fact, he is said to have pursued this to such an extent as to have dissected corpses without license. Several names which he gave to different parts of the body are still in use, as the 'Torcular Herophil,' the 'Calamus scriptorius,' and the 'Ducutum.' He placed the seat of the soul in the ventricles of the brain. Of his writings, only a few fragments remain, which have been collected and published in a dissertation entitled De Herophil Celerberrimi Medici Vita, scriptis, atque in Medicina Meritis (Götts. 1640).

HERO'S FOUNTAIN, a pneumatic apparatus, through which a jet of water is supported by condensed air. A simple mode of constructing it by means of a glass tube and a glass blower's lamp is shown in the annexed figure. The column of water in the tube a, compresses the air in b; this presses on the surface of the water in c, and causes it to gush out at d.

HEROSTRATUS, an Ephesian, who, from a desire of future fame, set fire to the magnificent temple of Diana, in 356 B.C. He expiated the deed by a painful death; and, by a decree of the Ionians, capital punishment was to be inflicted upon any one who should mention his name; a decree which produced an effect directly the reverse of what had been intended. The temple is said to have been set on fire on the night that Alexander the Great was born.

HERPES, a variety of disease of the skin, characterized by vesicles, sometimes as large as a split pea, occurring in clusters on an inflamed base, and ending in desquamation, after a course of a few days or weeks. In herpes zoster, or zona, the largest and most marked variety of the disease is the additional peculiarity, that it extends in patches around one side of the body, usually passing sharply up to the middle line, but not beyond it either before or behind. Herpes phlyctenules, zoster, labiales, praepatellaris circumcision, are the varieties of this disease most commonly met with in practice. The treatment is by soothing and cooling applications; there is no danger; but the smarting during the eruptive period, and the itching afterwards, are often very distressing. In the cases of the phlyctenoid type, and in some cases of the zoster, relapses are common; and the disease is to be regarded, in such cases, as recurrent. The treatment during these, as well as in the primary attacks, should be soothing, and the application of cold cream, and other simple soothing external applications.

HERPETOLOGY (Gr. herpeton, a reptile, and logos, a discourse), that branch of natural history which treats of reptiles. The Batrachians or Amphibians having, till recently, been included by naturalists generally—as they still are by many—in the class of Reptiles, the science of herpetology may be regarded as including the study of them. This branch of natural history received a share of attention from the naturalists of antiquity and the earlier naturalists of modern times. The name most deserving of notice in connection with it before the time of Linnaeus is that of Ray. In the end of the 18th c. and beginning of the 19th, H. received special attention from Lacépède, Bronnignat, Latreille, and Daudin, all of whom, as well as Cuvier, contributed greatly to its progress. More recently, it has been much advanced by the labours of Schlegel, Fitzinger, J. Gray, Muller, and Reichenbach, and the work of Spix on the Reptiles of Brazil is one of the most important contributions to herpetology. Bell's History of British Reptiles (Lond. 1839) contains a very full account of all the British species, including the Batrachians. This branch of natural history derives great additional interest from the numerous fossil remains of reptiles of former geological periods, and from the great size and extraordinary characters of many of them.

HERRERA, Antonio, one of the most eminent historians of Spain, was born at Cuellar, in the year 1549, and died at Madrid, 1625. His principal work is the Historia general de los Hechos de las Castellana en las Islas y Tierra Firme del Mar Oceano 1492—1554 (4 vols. Madrid, 1601—1613), which was afterwards published with continuations by Andr. Gonzalez de Barcia (4 vols. Madrid, 1728—1730). His Descripcion de las Indias occidentales (Madrid, 1601 and 1613) forms an introduction to the above work. Of his other works, the least valuable, are the Historia del Mundo en el Reyno del Rey D. Felipe II. 1554—1598 (3 vols. Madrid, 1601—1612); Commentarios de los Hechos de los Siglos III y IV, Francos y Vascos en Italia, 1281—1559 (Madrid, 1624); and the Historia de Portugal y Campiata de las Islas de los Agores 1582 and 1583 (Madrid, 1591).

HERRERA, Fernando de, a Spanish poet, was born at Seville, in the beginning of the 16th century. When advanced in life, he took orders, and died in 1569. He was master of the Greek, Roman, and Italian literatures, and was a man of prodigious learning. As a poet, he ranked so high, in the opinion of his contemporaries, that they bestowed upon him the appellation of the divine. Among his poetical works still extant, many of his erotic poems are remarkable for tender feeling; while his odes frequently display a lofty enthusiasm, but the expression is cast in too classical a mould, and consequently wears a certain air of artificiality. His Obras en Verso were published by Pacheco (Seville, 1582), and subsequently under the title Versos (Seville, 1619). They were republished in the Coleccion de Ramon Fernandez (Madrid, 1786; new edit. 1808). His principal historical work is the Relacion de la Guerra de Chipre (Seville, 1572); and he also translated from the Latin of Stapleton a life of Sir Thomas More.

HERRERA, Francisco, el Viejo, i.e., the Elder, one of the most eminent Spanish painters of
the school of Seville, was born in that city about the year 1576. He was the first to lay aside that tenuity in the use of the brush which we observe in the works of the older Andalusian painters. His drawing was bold and spirited, for which reason he may justly be regarded as the founder of a new and more national school. His 'Last Judgment,' painted for the church of St. Bernard at Seville, is a master-piece of drawing and colouring. The 'Holy Family,' and 'Outpouring of the Holy Spirit,' in the church of Sta. Ines, in Seville, are also much esteemed. The cupola of the church of Sta. Bona-
ventura displays his skill in fresco-painting. He likewise worked in bronze, a circumstance which may have led to the imputation cast upon him of coining false money. He died at Madrid in the year 1656. His easel-paintings and easel-drawings fetch very high prices. Some of his best works are in the Louvre at Paris. His youngest son, Francesco Herrera, El Mozo (the Younger), was born at Seville in 1622. He studied under his father, and afterwards went to Madrid, where he became so celebrated for his fish-pieces, that he received the surname of 'Herrera de los Pescados.' After his father's death, he returned to Seville, and painted for the churches. He subsequently went to Madrid, where he painted the altar of the dome of the church of St. Felipe and the chapel of Our Lady of Atocha, and died in 1655. There have been several other artists of the same name, but of less note.

**HERRING (Clupea harengus)**, a fish of the mala-
copous family Clupeidae (q.v.), is the most important of all fishes of the genus *Clupea*. The distinguishing features of the genus *Clupea* are small and numerous, and are situated not only on the body, but on the fins. In the mouth, the upper jaw is at the corner of the palate and the tongue. The H., of which we think it unnecessary to give any description, is found in the seas of the northern parts of the world, but more abundantly in those of temperate than of arctic regions. The opinion, once entertained, that its proper home is within the Arctic Circle, and that its vast shoals issue thence at certain seasons, migrating southward, and spreading themselves along the British and other coasts, is now discarded as utterly without foundation; and the H. is believed to be an inhabitant of deep water, from which, at certain seasons, it approaches the shores, probably never migrating to any great distance. The young are abundant in the shallow water near the shores, and disappear when the parent fish are absent. The H. seems always to deposit its spawn in comparatively shallow water, and is said to be very indifferent whether the spawning-ground be sandy, rocky, or covered with submarine vegetation. Certain localities, however, have the reputation of being favourite spawning-grounds. When the great annual shoals of herrings appear on the coasts, they generally swim near the surface of the water, and are followed by multitudes of larger fishes, as hakes, dog-fishes, &c., which prey on them; great numbers also fall a ready prey to gulls and other sea-birds, which congregate for the occasion. The food of the H. is a chieftain of minute crustaceans and octopeds; but it feeds also on small fishes, not scrupling to devour even the young of its own species. Herrings are sometimes, though rarely, caught on lines set for other fishes, and by persons angling from the shore; they are readily caught by means of a lure made of a white feather, which swims at the depth of some yards, the point of the fishing-rod being kept a yard or two below the surface of the water, the angler being in a boat which is in motion. The immense multitudes of herrings annually taken by the net cause no apparent diminution of their abundance, the destruction being compensated for by prodigious fecundity; more than 68,000 eggs have been counted in the roe of a single female. But herrings, without any apparent cause, often desert parts of the coast where for a time they have been remarkably abundant, and returning again in a few years fill up the lapse of a number of years. Some instances of this kind, in the western parts of Scotland, were popularly ascribed to steam-boats, when these first began to ply. The magnitude of the shoals of herrings is often enormous, and they have sometimes been driven ashore in far greater quantities than the inhabitants of the neighbourhood could find means of curing. An instance of this kind occurred, before the days of railways, at Crail in Fife. The water, as the tide came in, was so full of herrings, that a whole dozen could be taken out at one dip of a basket. Finally, they were stranded and left by the retiring tide in such numbers, that when all the salt within reach of the inhabitants of the place offered a shilling a cart for their removal as a nuisance.

There is evidence that the herring-fishery has been prosecuted in England since the beginning of the 8th c., and in Normandy since the 11th. Nor is it probable that the Scotch have ever been without fish-pieces, and the H. has sometimes evi-
dated flavour. The seas of other parts of the world produce a number of other species of the genus *Clupea*, as now restricted by ichthyologists. The off British *Clupeidae* are now referred to other genera.

The fishes popularly called Freshwater *Herrings* are *Salmonidae* of the genus *Coregonus*, to which also belong the *Herring Salmon* of the North American lakes and rivers. All of them are esteemed for the table.

**HERRING-FISHERY.** The herring-fishery is carried on all the year round, there being both a winter and a summer fishery; but the largest quantities of fish are caught in the months of August and September. The British herring-fishery, although it has no doubt become general on all parts of the British coasts.

The common mode of capturing herrings is by a set of large nets joined together, and known among fishermen as a 'drift.' These nets, held together by a back-rop, are let into the water in a straight line, and are kept perpendicular by a number of bladders or cork floats, balanced by a few slight weights of lead. Each single net is composed of three pieces worked into meshes of an inch square, and is 50 yards long and 33 feet in depth. These nets, which are now woven by machinery, were formerly made by the fishermen's families; but so many are used now, that it would be impossible to make all that is required in one season. Each fish-net has a train that extends nearly a mile in length.

The herring-fishery in Scotland is regulated by acts of parliament, and watched over by the Com-
mis-sioners for the British Fisheries. This Board will allow of no other method of taking the fish than by a drift-net. Another mode of fishing, known as 'trawling,' but which is in reality carried on by means of a 'scene-net,' prevails on some parts of the British coasts, but in Scotland, 'fishing' is illegal, and subjects those who practise it to heavy penalties.

362
The boats required in the herring-fishery in Scotland, although open or undecked, require to be of considerable size, in order to contain the large quantity of nets which are used, as well as to bring home the fish that may be taken. The fishermen also believe that the open boats are more convenient for the manipulation of the nets. Most of the boats used in Scotland are obtained from the port of Leith, which has been long celebrated for the build of fast and stong vessels. Each vessel is manned by a crew of five or six persons, one to guide the boat, and the others to manoeuvre the sails, nets, &c. The boat usually belongs to one person, who hires his assistance only, as in many cases, any two or three relatives, who form themselves into a crew, and share in the proceeds of the capture. The boats of a district usually gather to a particular centre, for the convenience of the curers. Some fishermen will proceed a hundred miles or more to a favourite port, and many of the curers have curing-stations at five or six different places. The boats proceed to sea as to arrive at the place selected for casting the nets about sunset, when the sail is shortened, and they are then partly planked over the boat, which requires to be kept in motion during the process. The last portion of the nets is fixed to the boat by a long swing-rod, and when the whole train is ready, the men go to rest; the boats and nets being allowed to drift with the tide. The herrings are caught by striking against the nets, in which they entangle themselves by the head. The herring-fishery partakes greatly of the character of a lottery, and sometimes the men obtain a large quantity of herrings, and as frequently take only a few; sometimes the nets are shot twice in a night, if no fish are got on the first trial.

The commerce carried on in herrings is peculiar. The fish are worked on, or, in some cases, are bearded ungutted by the 'cran,' a vessel which contains 55 gallons, and handed over to the curer. A very large proportion of the herrings taken on the British coast are packed or cured by means of salt; owing to the facilities for speedy transport afforded by railways, however, great quantities are also disposed of fresh. At Yarmouth, and some other parts of England, and also at some places in Scotland, the herrings are, after being slightly salted, made into what are called 'boilers,' by means of smoking. A large portion of the total catch is likewise made into 'rolls' by a more complete smoking, and both kinds are in great demand. Smoking-houses are now more numerous in many parts of Scotland than ever before.

The chief buyers of the fresh fish are known as curers; they provide salt, barrels, and labour, for the curing and packing of the fish. The curer, who is usually a person of considerable capital, contracts with the owners of the boats for a certain quantity of fish, usually 200 crans, for which he pays at a rate which has been arranged for long before the commencement of the fishery. In addition to a specified price per cran, a sum of money is usually paid down by way of bounty, and various privileges, such as dye-stuffs and drying-ground for nets, a few gallons of whisky, &c., are agreed for as well. Some curers will have as many as 250 boats fishing for them on various parts of the coast. The herrings are cured (in Scotland) under the inspection of an officer, and each barrel, if cured according to the instructions laid down by the Fishery Board, is entitled to a payment of 4s. 6d. to be marked with the government brand, as a mark of its quality. A large number of women are employed to gut and pack the fish, which they do with astonishing dexterity. The excitement and bustle at a large landing port during the herring season are remarkable, large numbers of people being employed in the various manoeuvres incidental to the capture and cure of the herrings. Amsterdam is said to have been built on herring-bones; but the Dutch herring-fishery, once of great magnitude, has been exceeded by that of Scotland, which is the largest in the world, and from which cured herrings are exported to the continent of Europe and to Ireland, and other countries, in large quantities. The only official statistics of the herring-fishery in Great Britain are published in a Report of the Fishing-Craft of Scotland, which are issued annually by the Commissioners of the British Fisheries. No account is kept of the quantity of herrings caught on the English coast, and there are no authentic statistics of the number or value of the boats engaged in this branch of the fishery.

From the most recent returns, it appears that there are 92,000 people employed in the various departments of the Scottish herring and other fisheries, and that the number of herring-boats in use at the various stations in 1861 was 12,861, representing in value a sum of £306,224; the value of the nets in use for the same period being £415,057. The report of the Herring-Craft of Scotland does not afford information on these points, and the details of the English herring-fishery cannot be separated from those of other branches of the fishery business.

Herring-fisheries have always been the subject of legislative protection in the United Kingdom, being considered a valuable branch of public industry. In 1860, an act of parliament, 23 and 24 Vict. c. 22, passed to regulate the Scotch-herring fisheries. By that act, the Commissioners of the British-White-herring Fishery may appoint a close season in some parts of the Scotch coast, there being a close season also fixed from January to May inclusive, as to the principal parts of the coast. The kind of fishing-boats and nets employed in the fishery is subjected to regulation. A penalty is incurred by selling fresh herrings during close time, 24 and 25 Vict. c. 72. The following are the more recent acts for the encouragement and regulation of the British-White-herring Fishery, 48 Geo. III. c. 110, 51 Geo. III. c. 101, 52 Geo. III. c. 133, 54 Geo. III. c. 102, 55 Geo. III. c. 94, 1 Geo. IV. c. 103, and 2 Geo. IV. c. 79, 5 Geo. IV. c. 64, 7 Geo. IV. c. 34, 1 Will. IV. c. 54, 6 and 7 Vict. c. 79, 10 and 11 Vict. c. 91, 14 and 15 Vict. c. 26, 23 and 24 Vict. c. 92, 24 and 25 Vict. c. 72. See Fisheries.

HERRING SILVER, a composition in money, in lieu of supplying a religious house with a certain number of herrings.

HERRISON (Fr. hérison), in Herlady, the hedgehog, a charge allusively borne by families of the name of Harris.

HERRNHUT, a small town in the circle of Bautzen, kingdom of Saxony, about 30 miles east of Dresden. It is pleasantly situated on the southern slope of the Hinterberg, from which it takes its name, and is noted throughout Germany for its fine and durable manufactures, particularly linen, japanned wares, and leather. H. is also remarkable for the regularity of its architecture, and the inhabitants for their cleanliness, freed from all ostentation, and quiet deportment. Pop. about 1100. H. was founded in 1722 by a colony of persecuted Moravians, who were1804, and the old Bohemian and Moravian Brethren. On coming into Saxony, they were sheltered and protected by the pious Count Zinzendorf, to whom H. belonged. From this place the United Brethren, better known as Moravians, have spread themselves over all parts of the world.
HERSCHEL, Sir William, born at Hanover, November 15, 1738, was the son of a musician, and was educated specially as a professional musician. In 1757 he went to England, where he became a teacher of music in the town of Leeds, from which he went to Halifax as organist, and subsequently (1766) in the same capacity to Bath. Here he would seem to have first turned his attention to astronomy. Wanting a telescope, and unable to afford a reflector, he made one himself, using a Newtonian, of five feet focal length, and with this applied himself to study the heavens. In 1780, he made his first discovery (Philo. Trans. 1780—1781), being a new planet, which at first of all for a comet. It was detected by an exhaustive process of surveying the heavens, which H. was the first to follow, taking the stars in regular series, and examining them all in their groups through the same instrument. The result of his diasyn mind was his appointment to be private astronomer to George III., with a salary of £400 a year. He then went to live at Slough, near Windsor, where, assisted by his sister Caroline (q.v.), he continued his researches. H. in 1761 married Mary Pitt, left one son, John (q.v.). Little is known of his private life. He was knighted by George III., and made a D.C.L. by the university of Oxford; he became, however, first to his wife's joy, and partly through selling mirrors for reflecting telescopes. He died at Slough, 23d August 1822.

H. contributed 69 papers to the Philos. Trans. between the years 1780 and 1815; and to the 1st vol. of Mem. of the Astron. Society, he contributed a paper, 'On the Places of 145 New Double Stars.' He greatly added to our knowledge of the solar system; he discovered Uranus and its six satellites, and two satellites of Saturn. Besides this, he detected the first of the many satellites of Saturn itself and that of Venus, the existence of the motions of binary stars, the first revelation of systems besides our own. He threw new light on the Milky Way and the constitution of nebulae, and, in fact, was the first to give the human mind any conception of the immensity of the universe. His catalogue of double stars, nebula, &c., and tables of the comparative brightness of stars, and his research in regard to light and heat, would of themselves entitle him to the first rank as an astronomer and natural philosopher. For a notice of H.'s telescope, see TELESCOPES. He erected one magnificent telescope, as it was then considered, of 40 feet aperture; it was begun in 1767, and finished 1787, on the 28th August of which year he by means of it detected the sixth satellite of Saturn.

HERSCHEL, Caroline Lucretia, sister of the astronomer, Sir William Herschel (q. v.), born March 1750, lived in Hanover till 1772, when she came to England to live with her brother at Bath. When William turned astronomer, she became his constant helper; and on his being appointed private astronomer to George III., she acted as his assistant, doing all the duties of an assistant astronomer, and in that character receiving a small salary from the king. While discharging her duties in this position, she found time for a series of independent observations with a small Newtonian telescope, made for her brother. Her special business was to sweep the heavens for comets, seven of which she discovered, in regard to five of which she has the credit of priority of discovery; and several remarkable nebulae and clusters of stars discovered in William's catalogues were described from her original observations. In 1798, she published, with an introduction by her brother, A Catalogue of Stars taken from Mr. Flamsteed's Observations, &c. This valuable work was published at the expense of the Royal Society, and contained 551 stars omitted in the British catalogue. She lived with her brother during the whole of his career, sharing his labours and distinctions, and on his death she returned to her native country. She was then 72 years of age, but she lived to be 98, retaining all her faculties to the last. In her last days, she was not idle. In 1828, the Royal Society conferred on her their gold medal for completing the catalogue of the binary stars observed by her brother. She was afterwards chosen an honorary member of the Royal Society. Miss H. died in 1848, after an uncommonly long life, distinguished by most useful scientific labours.

HERSCHEL, Sir John Frederick William, Bart., only son of the astronomer, William Herschel (q. v.), born at Slough, 1790, educated at St John's, Cambridge, where, in 1813, he became senior wrangler and first Smith's prize man. His first publication was A Collection of Examples on the Application of the Calculus of Finite Differences (1820). In 1822, he applied himself especially to astronomy, using his father's methods and instruments in observing the heavens. For a time, he worked with his wife and threw her his wife's journals and partly through selling mirrors for reflecting telescopes. He died at Slough, 23d August 1822.

H. contributed 69 papers to the Philos. Trans. between the years 1780 and 1815; and to the 1st vol. of Mem. of the Astron. Society, he contributed a paper, 'On the Places of 145 New Double Stars.' He greatly added to our knowledge of the solar system; he discovered Uranus and its six satellites, and two satellites of Saturn. Besides this, he detected the first of the many satellites of Saturn itself and that of Venus, the existence of the motions of binary stars, the first revelation of systems besides our own. He threw new light on the Milky Way and the constitution of nebulae, and, in fact, was the first to give the human mind any conception of the immensity of the universe. His catalogue of double stars, nebulae, &c., and tables of the comparative brightness of stars, and his research in regard to light and heat, would of themselves entitle him to the first rank as an astronomer and natural philosopher. For a notice of H.'s telescope, see TELESCOPES. He erected one magnificent telescope, as it was then considered, of 40 feet aperture; it was begun in 1767, and finished 1787, on the 28th August of which year he by means of it detected the sixth satellite of Saturn.
tackling and recording such observations in Southern Africa.

On his return to England in 1838, honours were showered on him. He had got the Royal Society's gold medal in 1836; he now was made a D.C.L. of Oxford; on Queen Victoria's coronation, he was created a baronet; he now succeeded the Duke of Sussex as President of the Royal Society; in 1848, he became President of the Royal Astronomical Society. In 1849, he published his Outlines of Astronomy, an enlargement of the publication in Lardner's Cycle. In 1850, he was appointed Master of the Mint. This office, on account of ill health, he resigned in 1855. The distinguished astronomer and mathematician is still alive (1863).

HERSE, or HEARSE (Play a move, a narrow; hence a frame for setting candles in), had originally quite a different meaning from that in which it is now used. The term was applied to a bier or framework with upright spikes for the reception of candles, and was used at the cere- monies of burial, and at funeral services. It was originally very simple in form, but in the 15th and 16th centuries an octagonal, and very splendid one came into use, and were erected in the churches over the bodies of distinguished personages. The framework was of iron or brass, sometimes of beautiful workmanship, square, octagonal, &c., in plan, with pillars at the angles, and arched framework above forming a canopy. The whole was hung over with rich cloths and embroidery, and lighted up with hundreds of wax candles, and decorated with wax images. From this the transition to the modern funeral hearse (see FUNERAL RITES) can be easily traced. In Catholic churches of the present day, the hearse still exists as a triangle with spikes, on which candles are placed.

HERSFELD, an old town of Hesse-Cassel, in the province of Hildesheim, situated on the left bank of the river Fulda, which here becomes an arm of 22 miles south-east from the city of Cassel. The cathedral, built in the beginning of the 12th c., on the site of an older cathedral that had been destroyed by fire, was itself set fire to by the French in 1761. It remains form a picturesque ruin. Pop. 7000, who carry on extensive manufactures of woollen cloth and serge.

HERSHIP, an old Scotch law term, denoting the offence of carrying or keeping cattle in common.

HERTFORD, a parliamentary and municipal borough, market-town, and capital of the county of the same name, is situated on the Lea, 26 miles north of London by rail. It contains few buildings of any architectural importance, but there is a branch of Christ's Hospital, a grammar-school, and several charity schools. H. carries on no manufac- tures; there are, however, lined-cake mills and several melting and corn-mills in the town and vicinity. There are here a fairly attended corn-market on Saturdays, and three cattle-marts during the week; the town returns two members to parliament. Pop. (1861) 6799.

The old castle of H. (nearly a fragment of which now remains) was built about 900. It was strengthened and repaired about the Conquest. The present castle is of the time of James I.; in the early part of the century, it was used as a college for the students of the East India Company's civil service. It now belongs to the Marquis of Salisbury, and is a private residence.

HERTFORDSHIRE, or HERST, an inland county of England, is bounded on the E. by Essex, on the S. by Middlesex, on the W. by Buckingham and Bedford, and on the N. by Cambridge. Area, 391,141; pop. (1861), 173,294. The surface presents a pleasing undulating country, largely wooded, with fertile valleys. The chief elevations are those of the chalk downs, a branch of the Chiltern Hills, which skirt the north of the county. The principal rivers are the Lea and the Colne, both afflants of the Thames. Chalk, at a greater or less depth below the surface, forms the basis of the soil, which is various, much of it being, however, a mixture of gravel and loam, with a tract of rich loam on the borders of Essex. Climate, mild and healthy. The agriculture of the county has improved very much of late years. Immense quantities of hay and straw are sold off the land, and sent to London. Throughout the county there are numerous gardens and orchards, the fruit of which is sent to the London market. Great quantities of malt are made in the county. Ware is the chief seat of the malting trade in the kingdom. Papier and straw-plait are extensively manufactured in the west and south. Three members are returned to parliament for the county.

HERTOGENBOSCH, or HERZOGENBOSCH. See Bois-le-Duc.

HERTZ, HENRIK, one of the most distinguished living Danish poets, was born in Copenhagen in 1798, of Jewish parents. In 1832, he rjured Judaism, and joined the Protestant Church. His first appearance as an author was in 1827, when he produced several clever vaudevilles and comedies, as Kjærlighed og Politl, Hr Burchardt og hans Familie, Jyskdragen, &c.; while three years later, appeared his Gjengangerlære eller poetiske Episoder fra Paradis, which exhibited such wonderful powers of imitating the style and spirit of other writers, more especially those of his countryman Baggesen, that public attention was at once arrested. Hertz, who had written anonymously, but the masterly manner in which he had moudiised the affectations and puerilities which had perverted the literature and criticism of the Danish press, produced a perfect ferment in the literary circles of Copenhagen, and before long to the discovery of the unknown writer. From this time his works followed one another in rapid succession; and striking out in an entirely different path from the one on which he had first entered, he produced, in 1837, a dramatic poem, Iren Dyrings Huis, founded on an old heroic saga, which, in the opinion of his countrymen, constitutes his masterpiece; among Germans, however, his lyrical drama of Kong Henning's Datter (1854) is the best known and most popular of his numerous works.

HERZEGOVINA is the name of a province belonging to European Turkey, and situated between Croatia, Bosnia Proper, Montenegro, and Dalmatia.

Under the Venetians, the H. was called the Dukedom of St Saviour; but in the later period, it was under the name of the county of Chlum; and in 1326, was annexed to the rank of a dukedom by the Emperor Frederic III. As early as 1406, the H. fell into the hands of the Turks, and has remained nearly more than two centuries afterwards the battle-field between Christians and Mohammedans. By the treaty of Carlowitz (1697), the H. was definitely annexed to the Turkish empire, with the exception of the town Castelmovo.
HERZEN—HESSE.

and its outkirts, which up to this day belong to Austria. In the early history of Hungary, the H. plays a prominent part, as Bosnia and Bulgaria were for a considerable period under the sway of the Hungarian crown. According to the present organiza-
tion of Turkey, the H. bears the name of the Sanjak Hasek, and belongs to the Evulet of Bosnia. Its physical aspect, as also its political and ethnographical character, coincide with those of Bosnia (q. v.).

HERZEN, ALEXANDER, a Russian author, was born in Moscow in 1812. Before he had concluded his university studies, he was seized, along with some of his fellow-students, on the pretext of maintaining sentiments hostile to the government; and after an imprisonment of about ten months, he was banished, in 1833, to Perm, not far from Siberia, and subsequently to Viatka and Novgorod. After 1842, he was permitted to reside at Moscow, under the strict surveillance of the police, and for some years devoted himself exclusively to literary works. In 1837, he left Russia, to visit other parts of Europe, and since 1852, has resided in London. In his own country, H.'s life was one long petty persecution. He was despoiled of his property, his works were subjected to the rigid censorship of the Russian censors during his travels, discovered to his extreme disgust, that he was 'attended' by Russian spies. H.'s literary performances are Dilet-
tention in Science (1842), Letters on the Study of Nature (1845—1846), Whose Fault is it? and Doctor Kroupof (both in 1847), Recollections of My Travels (1848), From the Other Shore, and Letters from France and Italy (1850). Since his residence in London, H. has published a variety of important works, among which may be mentioned, On the Development of Revolutionary Ideas in Russia (1851), Biographical Property (1853), or 'Serfism,' Prison and Exile (1854), My Exile (1855), Interrupted Tales (1856), France or England (1858), a pamphlet warning Russia against an alliance with Napoleon, and Memoirs of Catherine II. (1859).

HESIOD, next to Homer the earliest Greek poet of whom we have any knowledge, was born probably in the 8th c. a. C., at Ascra, in Brieotia, whither his father had emigrated from the Eolian Kyrene, in Asia Minor. He seems to have been at the same time a shepherd or herdsman, and from humble circumstances—in his Works and Days, he speaks of himself as atimilos, 'unhonoured,' 'noted.' He afterwards left Ascra, and went north to Orchomenos, on Lake Copais, where he dwelt during the remainder of his life, and where in later times his tomb was shown. This is really all we know about H., for the marvellous stories of the Neo-Platonists afford us no intelligible clue to his personal history; and in the opinion of some critics, even throw grave doubts on his historical reality altogether. This, however, is probably too extreme a view. While it may not be necessary to reject the personality of H., it may still be allowed that he was a 'representative man,' the founder and head of a school of poets— the Breetian or Prician—who stand in striking contrast with the older Ionic or Homerice school. Their original region was at the foot of Mount Helicon, whence they spread over Beotia, Phocis, and Euboea. Their language and versification were nearly the same as those of the Homerice school, but in all other respects they appear to have been different, and even antagonistic, ignoring the grand themes, and the character of the heroic age, and preferring to sing of rural quietude and peaceful pursuits, the simple sanctities of household life, the homely duties of thrift, the education of children, and the prosaic details of commerce and politics. Hence the Spartan Cleomenes, scornfully termed H. the 'poet of helots,' while Homer was the poet of warriors. In fine, it may be said that the poetry of the Hesiodic school presents an advanced civilization, morality, and thought, on the Homerice school.—The works either written by or ascribed to H. are seven in number, of which the following are the more important: 1. Erga kai Hermerai ( 'Works and Days'), in the time of the latter Emperor, the only one ever to be truly H.'s by the people about Mount Helicon; 2. Theogonia ( 'Generation of the Gods'), not considered genuine by H.'s countrymen, nor by most modern critics; 3. Enoi or Eoini Megaloi, called also Katafogoi Genikai (Catalogues of Women). Of these the first two are entire; while the well-known Aesis Heraleos ( 'Shield of Hercules') is supposed by some to be a relic of the third. The Hesiodic poetry was, in ancient times, if not warmly admired, at least held in great veneration. Both the priesthood and the philosophers considered the Theogony a great, in fact, the greatest authority, on the subjects of which it discourses, and almost all the Alexandrine critics earnestly devoted themselves to its elucidation, but their commentaries have unhappily perished. Only here and there among the School of the later Neo-Platonists some of their ancient commentaries have been preserved. The best collection of these is to be found in Gaisford's Poeta Graeci Minoris. The first edition of the Hesiodic poems appeared at Milan in 1493; subsequent editions are those of Hennan (Amsterdam, 1667), of Robinson (Oxford, 1737), of Gaisford (1817), of Gaisford (vol. i. of his Poet. Gr. Min.), and of Gottling (Gotha and Erfurt, 1831; 2d ed. 1843).

HESPERIDES, the name of the famous sisters who, assisted by the dragon Ladon, guarded the golden apples which Hera had received, on her marriage with Zeus, from Go. Their genealogy, as well as their number, are variously given by mythologists. The locality of the gardens was also a matter of controversy, the two favourite opinions placing them westward of Mount Atlas, and north of the Cauccasus. The apples were stolen by Heracles (q. v.), but were afterwards restored by Athena.

HESSE (Ger. Hessen), a territory of Germany, occupied, in ancient times, by the Catti or Chatti, who first became known to the Romans in the year 15 a. d., when Germanicus destroyed their principal settlement of Mattium, the site of the present villages of Gross and Klein Maden, near Gotzen-
berg. In the course of time, the Catti, who were settled in the districts now known as Upper and Lower Hesse, gradually merged in the Frankish tribes, with whom they took part in the great emigration into Belgium and Gaul, after which the territories which they had evacuated were occupied by Saxons, who thenceforth kept possession of the land known in after-ages as SAXON Hesse. The power of the old chieftains had, in the meanwhile, become so firmly established under the Frankish empire, that on the fall of the Carolingians, in 911, Conrad I., Duke of Franconia and Hesse, was elected to the vacant throne of Germany, as being the most powerful of the old Hessian chieftains. The two branches of the Hessian family still extant are descended from Heinrich I., surnamed the Child (died 1306), son of Sophia Duchess of Brabant. Although he himself exercised little real power owing to the dismemberment of Hesse into semi-independent principalities, his descendants gradually reunited these disjointed domains, and added many valuable territories on the Rhine to
HESSE—HESSE-CASSEL.

their old patrimony. Philip I., the Magunimoons, who succeeded his father, Wilhelm II., as a minor, in 1599, introduced the Reformation into H., and founded the university of Marburg, with the revenues of the secularised convents and monasteries. This prince took an active part in the peasant and religious civil wars of his day; and by a will made in 1562, divided his territories among his four sons, who succeeded to their allotted possessions on his death in 1567. The eldest, Wilhelm IV., obtained the southern portion of the land, which he founded for his residence; Ludwig, a fourth part, with Marburg; Philip, an eighth part, with Rheinfels; and George, an eighth part, with Darmstadt. The death of Philip and Ludwig left all the Hessian dominions in the two main lines of Hesse-Cassel and Hesse-Darmstadt (q. v.).

HESSE-CASSEL (Ger. Hessen-Kassel, Kurhessen, or Electoral Hesse) consists of one large and five smaller districts—the former extending in an irregular form from 50° 3' to 51° 40' N. lat., and from 8° 35' to 16° 12' E. long.; while the latter, which comprise the countship of Schaumburg and Schmallkald, a part of Henneberg and Barciaith, and various townships, are impacted within the territories of other states. H.-C. is bounded by Prussian Westphalia, Wabken, Hesse-Darmstadt, Nassau, Frankfurt-on-the-Maine, Lower Franconia, Prussian Saxony, and the principality of Göttingen.

Hesse is divided into the following provinces or circles:

Giving for the whole electoral duchy a square area of 3047.7 miles, and a pop. of 272,686.

Physical Character.—The country is generally hilly, and in some places even mountainous, forming a part of the great central elevated plateau of Hanau, and the most considerable of the ranges are the Halberstädter Wald, the Thuringerwald, of which the greatest elevation is the Iedelsberg (2500 feet), the Mosel (2000 feet), the Hainbrück, Kellermars, and Reinhardswald.

The principal rivers are the Werra, with its numerous small affluents, but which only belongs in part to H.-C.; the Fulda, whose course appertains almost exclusively to this duchy; the Eder; and as boundary rivers, the Weser, Maine, and Lahn.

Climate, Soi, Products.—The climate is generally mild, but in some of the mountainous districts, as the Rhöngebirge, it is at times very severe. The mean annual temperature is 48° 5 Fahrenheit.

The soil is almost exceptionally fruitful and well adapted to agriculture. Cereals of all kinds yield good returns. The most cultivated districts are in the south-west of Hanau, where much fruit and some good wines are produced. Flax is grown in Schaumburg and Lower Hesse, and tobacco in the valleys of the Werra. It is estimated that for every hundred the land is distributed nearly in the following ratio: woods, 40; arable land, 37; meadow land, 11; miscellaneous, 12.

The mineral products comprise copper, lead, coal, salt, and salt, the last three of which are the property of the state. The mountain districts have many good mineral springs, the most important of which are those at Schwalm, Wilhelmsbad, Hungenmar, Rodenberg, and Nenneldorf.

Industry, Imports, and Exports.—Trade.—In addition to agriculture and the rearing of cattle and other animals, the chief branches of industry are the weaving of linen and yarn, which, although everywhere practised, is prosecuted with most vigour about Fulda and Marburg. There are good steel and iron works at Schmallkald, and manufacturies of guns at Cassel, and porcelain, glass, paper, and gold and silver wire-works in Hanau and other parts of the electorate. The exports consist principally of yarn, flax, lineas, iron and steel wire, fine clay, wool, leather, grain, dried fruits, and mineral waters. The transit trade is considerable, and is principally conducted by way of Hanau, Carlshafen, and Eschwege. The internal commerce centres more in Cassel and Hanau, where, as well as at Spangenberg and Schmallkald, annual commercial fairs are held. H.-C. has between 900 and 1000 miles of good public roads, and upwards of 200 miles of railways, in addition to which it possesses great facilities for internal trade in its numerous navigable rivers.

Receipts, Expenditure.—According to the budget of 1835—1860, the annual receipts of the electorate are about 3,700,000 thalers, and the expenditure so much less as to leave an annual surplus of about 95,000 thalers. The national debt in 1861 represented a capital of 3,700,000 thalers, but this was exclusive of 81 million thalers raised for the construction of railways, and 14 million thalers extraordinary loans.

Army.—The army, since 1848, has been kept at 12,000 men, of whom 5000 are on the reserve list. Military service is compulsory between the ages of 20 and 30 years.

Education.—There are about 1300 national schools, ten gymnasias, six normal, and various polytechnic, theological, military, and other schools. H.-C. has one university at Marburg, memorable as being the first which was founded (in 1527) after the Reformation and without papal authority.

Religion.—The majority of the population belong to the Reformed or Calvinist faith, which is also the profession of the electors, but other creeds present the following numbers: Lutherans, 134,000; United Protestants, 100,000; Catholics, 100,700, half of whom belong to Fulda; Jews, 16,000. All the churches recognised by the state enjoy equal rights.

Law.—The supreme court of appeal is at Cassel, with two high courts of justice at Cassel and Fulda, under whose jurisdiction are various criminal, and 87 magisterial courts.

The electorate of H.-C. has a limited monarchical government. The ruler bears the title of Electoral Prince and Landgraf of Hesse, Grand Duke of Fulda, Prince of Hersfeld, Hanau, Fritzlar, and Isernburg, Count of Katzenellenbogen, Dietz, &c.

The dignity, which is hereditary in the male line only, is, at present held by the Elector Frederick Wilhelm I. The elector is assisted in the government by a council of ministers, who are partially responsible. A new constitution, based on the federal decision of 1857, was promulgated in 1860. There are two representative chambers, the higher of which comprises the princes of the electoral family, several Miscellaneous Princes (q. v.), state, and large landed noble proprietors; while the lower chamber comprises 48 members, one-third of whom represent the landed proprietors, and the remainder the civic and rural districts. The chambers must be convened at least once every three years. Each parish is presided over by a burgomaster (Bürgermeister) or magistrate, each circle by a government official, and each province by a special governor.
HESSE-CASSEL—HESSE-DARMSTADT.

H.-C. occupies the eighth place in the German Confederation. It has three votes in the Plenum or general council of the diet, and supplies a contingent of 6626, and a reserve of 2940 men to the federal army.

History.—Hesse-Cassel is the elder line of the House of Hesse, founded by Landgraf Wilhelm IV., or the Wise, son of Philip the Magnanimous, who reigned in 1720, and continued on his court at Cassel. Wilhelm was succeeded by his son Maurice, who joined the Protestant Church, and five years before his death resigned the government in 1627 to his son Wilhelm V. The latter fought on the side of Sweden during the Thirty Years' War, for which he was put under the ban of the empire. His two brothers, Hermann and Ernest, respectively founded the lines of Hesse-Rotenburg and Hesse-Rheinfels; and on his death in 1637, his widow assumed the regency for their young son, Wilhelm VI., and by her ability, secured for him, as an indemnification for the losses which the country had sustained during the war, the greater part of Schaumburg and the principality of Waldeck. The successor of Wilhelm V. pursued the practice he had begun of hiring out Hessian soldiers to fight in the service of foreign princes, a practice by which the finances of the state were considerably augmented. The expense of the war raised the expense of the poor, and the morality of the people; while, in some instances, it led to the formation of important alliances on the part of the reigning House. The landgraf, Friedrich I., who succeeded his father in 1730, had no immediate son of his own, and his wife, the Princess Ulrike Eleanor, sister of Charles XII. His brother, Wilhelm VIII., to whom he had resigned his Hessian territories, fought under the British and Hanoverian flag in the Seven Years' War, and gained considerable results for himself and his troops during the course of the war, which was especially disastrous to the welfare of his states. Wilhelm's son, Friedrich II., persevered in the same course, and kept up a splendid court on the proceeds of the pay, amounting to £3,000,000, which the British government gave him for the services of the 22,000 Hessians who fought against the Americans in the war of independence. Friedrich, who had become a convert to the Roman Church, died in 1756, and was succeeded by his son, Wilhelm IX., who reigned as Wilhelm I., after his elevation to the rank of an elector in 1806. This prince frequently shifted sides and parties during the French revolution and imperial war, and was with his Hessian mercenaries first under British colours, then in conjunction with Prussia, and in 1806 as the ally of Napoleon, who in return for his aid promised to respect the neutrality of the electorate. After the battle of Jena, the French emperor, suspecting the motives which had actuated the elector in augmenting his army, threw troops into the Hessian territory, and at the peace of Tilsit incorporated the electorate in the newly formed kingdom of Westphalia. In 1813, Wilhelm returned to his dominions after the overthrow of French power in Germany, and at once began to restore the old order of things as far as he could; while he entered upon a course of painful legislation to recover the state lands that had been sold during his exile, and appealed to the diet with such importunate sincerity for indemnification, that he obtained various important concessions at the congress of Vienna. Although he failed in his wish to secure the title of king, of which he was especially ambitious. In accordance with the promise which he had made his subjects on his restoration to power, he summoned a body of jurists to construct a constitution, but no sooner was a draft of this new scheme completed, than he refused to fulfill his promises. His death in 1821 was regarded as a fortunate event for the electorate; but his son and successor, Wilhelm II., by his narrow policy, increased the rapidly growing disorders of the state, while his relations to his mistress, the obnoxious Countess of Reichenbach, rendered him peculiarly unpopular with his subjects. These disorders were partially arrested by the retirement of Wilhelm in 1831, in the formation of the electoral prince to the rank of regent. But the history of the 16 years' regency of Prince Friedrich Wilhelm exhibits only a series of intrigues at court, dissensions between the government and the representatives of the people, and a retrogressive policy, which left H. far behind other German states in material prosperity. The death of the old elector at Frankfurt, whither he had retired on his abdication, raised the regent in 1847 to the rank of sovereign elector. The revolution of Paris, in 1848, extorted from the terrified prince many liberal promises of reform, some of which were redeemed; but in 1850, after revoking many of his pledges, he made an agreement with the Vogelsberg and Hessen-Darmstadt and Haynau to govern the country. Haaschpling's measures at length drew upon him a public charge of maladministration and treason; and he having surrendered himself to the authority of the emperor, should he would be endangered if he remained longer among his subjects, the prince and his minister fled by night from Cassel to Wilhelmshaid. On the 17th September 1850, an ordinance proclaimed that the seat of government had been transferred to the latter place. Haaschpling appealed to the Confederation for its intervention, and H. became the rendezvous of troops; the Austrian and Bavarian contingents occupying the south, and the Prussians, appointed for the north, leaving the elector, taking their position in the north. The threatened war was principally limited to angry protocols, but the result of the intervention was the restoration of the elector, who returned to Cassel. In 1852, a new constitution was promulgated, which in no way satisfied the people, whose conduct throughout the trying crisis had been marked by forbearance and moderation. The policy of the government remained unchanged notwithstanding all that had occurred; arrests were frequent, and many of the best of the civil and military officials tendered their resignation, rather than continue in the service of the elector. Various constitutions have been proposed to the people, but rejected by the Chambers; and that now in force may be regarded as merely provisional.

HESSE-DARMSTADT, a grand duchy of Germany, extending (exclusive of small outlying portions) between 49° 24' and 51° 7' N. lat., and 7° 50' and 9° 40' E. long., consists of two nearly equal parts, which are separated by a strip of land belonging to Hesse-Cassel and Frankfurt-on-the-Maine. The northern district, which is bounded by Hesse-Cassel, Nassau, and Prussia, is mountainous, being intersected by the Vogelsberg, and the rivers the Taunus and Westerfeld; while the southern district, which is bounded by Hesse-Cassel, Bavaria, Baden, Prussia, and Nassau, is level, except in the east, which is occupied by the mountain-range of the Odenwald. H.-D. is divided into the following provinces:

325
HESSE-DARMSTADT.

Giving an area of 3206.7 square miles, and a population of 845,571 for the entire duchy.

Physical Character.—H.-D., which presents a succession of fruitful valleys and rich mountain slopes, is well watered, being traversed by the Rhine and Maine, Neckar, Nahe, Lahn, Nidda, Eder, Nalter, and Wetter. The climate of the northern districts of H.-D. is very much more severe than that of the southern. The latter is in the Rhine-Homburg district, which shares the climate of South Germany.

Agriculture is in a very flourishing condition, nearly half of the soil being occupied by arable lands. Corn is grown in sufficient quantity for exportation, chiefly to Upper Hesse, where Indian corn, or maize, and flax are also largely cultivated, while hemp, tobacco, and poppies are raised in Rhenish Hesse. The southern districts, in which a great variety of fruit is grown, including figs, almonds, chestnuts, &c., are specially noted for the excellence of their wines, the choicest of which are the Niesterlein, Lahnbach, Bodenheimer, and red Ingeheim, grown in the vicinity of Mainz, the Schlachberger near Bingen, and the Liebfraumilch in the districts of Wurttemberg.

The mineral products, which are inconsiderable, include copper, cobalt, iron, salt, and coal, the three latter of which are most abundant in the Wetterau district.

Industry.—The principal branches of industry are, besides agriculture, the making of wine, which in good years yields a return of upwards of four million thalers; the manufacture of cottons, linens, and stockings, and the weaving of straw for Upper Hesse; the preparation of oils and leather; and the manufacture of paper, snuff, paper-mâché goods, &c. H.-D. has 1100 miles of post-roads, and about 1290 miles of railway; while the steam-navigation of the Rhine, the Lahn, and the Oder—besides the navigable canal—the system of canals in the vicinity of Giessen, and the new river-railway line, extending from Mainz through the Sieg and Lahn, and limited by the lower Rhine, are all in existence. The Rhine offers abundant water power and the best system of canals in the world.

Revenue.—The budget for the years 1860—1862 gives the following estimate of the financial condition of the grand duchy: annual receipts, 9,096,664 florins; annual expenditure, 9,066,796 florins, leaving a surplus of 29,868 florins. The public debt, exclusive of the loans made for the construction of railways, amounted in 1860 to 6,470,000 florins.

Army.—The army comprises in all 10,618 men, the term of service is for six years, the latter two of which include the reserve service. There is a military college at Darmstadt.

Education.—In 1829, there were 1756 national schools, 9 normal, and 1 higher burgher school, while the educational wants of the higher classes are well supplied by the university of Giessen (q.v.), with its noble library, and the 24 scientific institutions connected with it; by 6 gymnasia, and by polytechnic, military, and theological schools. The chief towns support various scientific and literary societies, and the duchy generally is favourably distinguished in respect to the diffusion of knowledge.

Religion.—In regard to religion, the population may be divided as follows: Lutherans, 400,000; Reformed Calvinists, 29,000; Catholics, 218,000; Unitarians, 165,000; Jews, 29,000; various sects, 30,000. The Lutherans have a consistory at Darmstadt, with three minor courts under its jurisdiction, while the Roman Catholic churches are under the supervision of a bishop, who has his seat at Mainz. There is a supreme tribunal of law at Darmstadt, with lesser courts at Darmstadt, Giessen, and Mainz, and numerous local courts in the country districts, in some of which trial by jury prevails.

Political Constitution, &c.—H.-D. supplies a contingent of 7227 men, with a reserve of 3098 to the federal army, occupies the ninth place in the German Confederation (q.v.), and has three votes in the Plenun or full council, and one vote in the limited council. It is a limited monarchical state. Its ruler, who must be a Lutheran, bears the title of Royal Highness, and ranks as Grand Duke of Hesse, and as a Rhineland grand duke. The succession is hereditary in the female line, and in case of male issue. In accordance with the law of 1856, there are two legislative chambers of representatives, which must be convoked at least once in every three years, but the real power of the government rests with the council of state and the five ministers, into which the several branches of the administration are divided.

History.—The line of H.-D., the second main branch of the House, is derived from the Hessian count, George I., who, on the death of his father, Philip the Magnanimous, in 1567, obtained the upper countship of Katzenellenbogen, with the town of Darmstadt for his residence; and succeeded in 1583, on the death of his brother without issue, to the grand-ducal title. He was succeeded in 1596 by his eldest son, Ludwig V., who, in 1633, married, in accordance with the marriage contract of 1596, Louise, daughter and heir to Philip, Elector of Hesse, and thus became the founder of the Hesse-Homburg line (q.v.). Ludwig V., who acquired a portion of Upper Hesse, was the founder of the university of Giessen. Although H.-D., like every other part of Germany, suffered considerably during the French revolutionary wars, it finally acquired a great addition to its territories through the agency of Napoleon. Ludwig X., who had succeeded his father as landgraf in 1791, joined the Confederation of the Rhine, and after having acted against Austria in 1809, and in concert with the French in 1813, offered, after the battle of Leipsic, to waste his wealth in support of the allies against France on condition of being allowed to retain his various acquisitions of territory. He had assumed the title of grand duke in 1806, and on that occasion he promulgated various legislative edicts, and annulled the pre-existing union of the H.-D. and the Hesse-Cassel duchies. In 1814, he joined the German Confederation, and made large cessions of territory to Prussia, Bavaria, and Hesse-Cassel, receiving by way of indemnification a portion of the French department of Donnersberg, or Mainz, extending to the Lahn, and the greater part of the principality of Isenburg, in right of which he assumed the additional title of a Rhineland grand duke. In accordance with the decree of the federal diet, Ludwig X. gave up his succession as a grand-ducal house, and entered into a treaty with France, by which he gained for his son, Ludwig II., a free and sovereign state, the plan of which was, however, so obnoxious to the assembled states, that the grand duke and his advisers were compelled to withdraw it, and to substitute another in its place. The task of framing this constitution occupied several diets in succession, and gave rise to much angry discussion within and without the chambers. The death, in 1830, of the grand duke, who from various causes was endeared to his subjects, widened these differences, and angry discussions soon arose in regard to the civil list to be accorded to the new grand duke, Ludwig II. In the course of the next few years, one diet after another was convoked and dissolved, but no material change was effected in the relative position of the chambers and the government. The death of the grand duke, Ludwig II., in 1848, and the accession of his son, Ludwig III., who, in 1854, took the title of a grand duke, was attended by little change for the better. In the meantime it must, however, be admitted that, notwithstanding frequent dissensions in church and state, the duchy made considerable progress in matters of internal education. The railways were opened, and new roads formed;
monopolies and other commercial restrictions removed; greater freedom permitted in the curri-
culum of the university, and a more liberal spirit infused into the system of the education imparted in the national schools. Although these and many other improvements were gradually yielded, they have been permanent, but the character of the grand ducal policy has neither been liberal nor in accordance with the wishes and views of the majority of the people.

The little town of HOMBURG, a German landgravie, consists of the provinces of Homburg and Meisen-
heim; the former of which is bounded by Hesse-
Darmstadt, Hesse-Cassel, and Nassau, and the latter by Rheinish Franconia and the Bavarian palatinate.

</table>

Giving 105-94 square miles for the superficial area, and 25,746 for the population of the entire land-
gravie.

The former of these provinces is a fruitful district lying on the slopes of the Taunus Mountains, which produces grain, wine, and timber; while the latter is mountainous, and yields large quantities of coal and iron, and some excellent wine.

ESTABLISHMENTS. - The budget for 1860—1861 gives the following amounts: viz., receipts, 4,099,964 florins; expenditure, 3,755,566 florins, leaving a surplus of 34,440 florins. The debt was, in 1861, 1,920,861 florins.

The troops of the landgravie are 333 men, including a reserve of 100, which comprise the contingent of H.-H. to the federal army. H.-H. is represented by Hesse-Darmstadt in the limited council of the diet, but it holds one independent vote in the Plenum or full council. The estab-
lished religion is Protestant, to which 19,600 of the inhabitants belong, the great majority of whom are attached to the Reformierte Kirche, while there are 4109 Catholics, and about 1000 Jews. H.-H. has a legislative representative chamber, and the government is divided into the three departments of Justice, the Interior, and Finances.

The landgravie was an integral part of Hesse-
Darmstadt (to which it will revert on the failure of the direct line), till it was transferred, on the death of the landgraf, in 1596, to his younger son, Friedrich I., in whose family it has since remained as an independent state. Little change was effected in the province till the congress of Vienna, when it was augmented by the addition of Meissenberg.

In 1817, H.-H. was admitted into the German Cong-
federation. In 1850, disturbances broke out in Meissenberg; but although they were soon quelled, in consequence of the powers accorded to the landgraf by the diet, several severe edicts were published in 1832 against the liberals, which excited considerable disaffection. The opening of the springs and baths at Homburg in 1855 proved an unex-
pected source of wealth to the state, and since the addition of gambling saloons, the establishment has constituted a very important branch of the revenue. Attempts have more than once been made by the diet to put down the gambling-salons; but since the pressure of federal intervention has been removed, gambling has been resumed with fresh spirit; it is understood, however, that the land-
graf has pledged himself to the final closing of the gambling salons after a limited term. Since their first opening, play has, with only temporary abatement, been prosecuted at all hours and seasons by all ranks, from peasants to princes and princesses, and almost at all ages, excepting among the subjects of H.-H., who are stringently forbidden to participate in it.

In 1835, H.-H. joined the Zollverein (q. v.). The reigning landgraf, Ferdinand I., Brother Friedricli, and his successor, Philip August, in 1844, so far yielded to the wishes of his subjects for a constitutional government, as to convocate a diet to deliberate on its nature; but when the scheme of government was completed, he withdrew his promised consent, and the course of public affairs resumed the old track. See Von Klöden's Ent-
kunde; Steidle's Atlas; Ritter; Almanach de Goba, 1862; Germanic Empire in Lardner's Cyclopaedia.

HESSIAN FLY (Cecidomyia destructor; see CECDOMYIA), a dipterous insect, the larva of which has often proved extremely destructive to wheat in North America. Its ravages have occasionally even led to the abandonment of wheat culture for a time in considerable districts.

It is black, with dusky wings, darker at the base, pale-brown legs, black feet, and antennae. There are two broods in the year.

The maggots of the one brood live at the roots of the plants throughout the winter; those of the other are found in the lower joints of the straw, in the early part of spring and beginning of summer.

HESYCHASTS (Gr. Hespheko, to be quiet), a mystic and contemplative sect of the Greek church, who renewed in the 14th c. the errors and practices of the older Euchites, and who may be described as the Quietists of the East. There is reason to believe that the principles of the ancient mystics never entirely died out among the Oriental monastic bodies; but they attracted an unusual share of public attention not only at home, but in the western church in the earlier half of the 14th century. A Basilian monk, named Barlaam, a native of Calabria, the ancient Magna Graecia, and himself of Greek origin, in the course of a visit to the monasteries of Greece, observed among the monks several practices and doctrines which he considered objectionable, and was particularly struck by the doctrinal abuses of the monks of Mount Athos, the 'holy mountain,' the great strong-
hold of monasticism in Greece. In common with the mystics of all times, these monks placed all per-
fec tion in contemplation, and in the elevation and sublimation of the soul which contemplation produces. But among many practices which he considered objectionable, there was one which especially provoked his reproval, and, indeed, his ridicule. Believing that in the soul lay hidden a certain divine light, which it was the office of contempla-
tion to evoke, they withdrew at stated times to a retired place, seated themselves on the earth, and fixed their eyes as it were on the centre of the stomach (whence the sobriquet by which they were known, amphalopaych, navel-soul); and they averred that, after the allotted time of contempla-
tion, a kind of heavenly light beamed forth upon their soul (where so they held, was in that region), and filled them with ecstasy and supernatural delight. They declared that this light was the glory of God himself, and they connected it in some unexplained way with the light which is beheld in the transfiguration of our Lord upon Tabor. Barlaam denounced these notions as fanatical and superstitious. On the other hand, they were explained and warmly defended by Gregory I Alaman,
the Archbishop of Thessalonica; and in order to settle the controversy, a council was held in Constantineple in 1341, which terminated in the triumph of Palamists and the monks. The controversy afterwards turned upon a point of doctrine—namely, on the nature of the soul. The monks of Curier, with which are ranked the 'zoophytes,' of the division Polypoda or Bryozoa. The nervous centres or ganglia are not arranged in a longitudinal series of symmetrical pairs, but are variously distributed in different parts of the body; one principal ganglionic mass, however, occupies a position above the gullet, with which all the nerves of the special senses which exist are connected. With it, also, all the other ganglia communicate. Whether or not the new name heteroganglial, may ultimately come into general use among systematic zoologists, it certainly indicates a most important character in the organisation of the annals to which it is applied.

HEYMANN, or ATAMAN, the title of the head or general of the Cossacks, now retained only among the Cossacks of the Don. From the earliest times the H. was elected by the voice of the assembled people; the mode of election being by throwing their fur-caps at the candidate they preferred, and the one who had the largest number of caps was declared duly elected. The power of the H. was very great, and extended over life and death. When the Cossacks, in 1634, submitted to the Russians, the H. was permitted to retain his rights as formerly. The Empress Catherine entirely abolished the dignity of the H. of the Ukraine, and substituted a government consisting of eight members. The Don Cossacks have, indeed, retained their H., but even he possesses but the shadow of his former power. The last elective H. was Count Platoff, who played a prominent part in the wars with France (1812–1814). After his death, the H. was appointed by the czar, and ultimately the title was made hereditary in the grand duke, the heir to the throne.

HEYELEIUS (known also as HEYEL or HÖVELKE), JOHANN, one of the most celebrated astronomers of the 17th c., was born at Danzig in 1611, and died in that city in 1677. He belonged to an honourable and wealthy family; and in 1641 he erected an observatory in his own house, and furnished it with large telescopes constructed by himself. He published numerous astronomical works. H. was the first astronomer, with the exception of James Bradley, to observe a transit of Mercury (Gassendi's observation was made in 1631, that of H. in 1661); and it is now generally conceded that he ranks next to Flamsteed amongst the astronomers of his day. Delambre devotes ten pages to the notice of his labours in his Histoire de l'Astron. Mod., and his life has been written by J. H. Wenshal (Königsh. 1820).

HEYES, a small town of Hungary, in the county of the same name, is situated in the midst of a productive flatland, 60 miles east-north-east of Pest. Pop. 5700.

HEXACHORD, a name given by the ancient Greeks, in their music, to the great sixth. In modern music, hexachord denotes the six diatonic degrees of which Guido formed his scale, better known by the six syllables, Ut, re, mi, fa, sol, la, to which the scale was sung.

HEXAGON (Gr. hex, six, and gōnin, angle), a figure of six sides and six angles; when the sides and angles are equal, it is called a regular hexagon. If a regular hexagon be inscribed in a circle, the radius of the circle is equal in length to each side of it, and by joining the centre with the angular points, six equilateral triangles will be formed. This property of the hexagon furnishes a very simple...
method of dividing a circle into six equal parts, and at the same time constructing the hexagon, by merely laying off round the circle lines equal to the radius of the circle. Of which there are complete existing hexagons, of which the hexagon contains the greatest area within a given perimeter, the proportions between the three different figures being nearly as the numbers 4, 5, 6. It is thus that bees, by making their cells of a hexagonal form, enclose the greatest space with the least expenditure of wax.

**HEXAHEDRON** (Gr. 

**HEXAMETER** (Gr. 

HEXHAM, a small market-town of England, in the county of Northumberland, is agreeably situated on the right bank of the Tyne, 20 miles west of Newcastle. The Tyne is here crossed by a bridge of nine arches. The priory church, an old cruciform structure of the 12th c. is now used as the parish church. It has a lofty central tower, and at its western end are remains of the magnificent monastic buildings of the 7th c. by St Wilfred. The chief manufacturers of the town are glovers and Tis. Pop. (1861) 5270.

**HEYLIN, Dr Peter,** an English divine, of considerable note in his own day, was descended from an ancient Welsh family belonging to Montgomeryshire, and was born at Burford, in Oxfordshire, November 29, 1600. He studied at Oxford, where he took the degree of D.D. Through the interest of Laud, in whose theory of church and king he devoutly believed, H. was appointed chaplain-in-ordinary to King Charles in 1629. Subsequently, he held a variety of livings, but was deprived of them during the period of the commonwealth. At the restoration, he was made sub-dean of Westminster, an office which many of his friends thought an utterly inadequate reward of his literary services to the royal cause. He died May 8, 1662. H. was a very voluminous controversial writer, but his works are of no value now, except as illustrative of the age in which he lived, and the ecclesiastical party to which he belonged. Of some of these works may be mentioned, *History of the Sabbath;* *Ecclesia Vindicata,* or the Church of England Justified; *Theologia Veterum;* and *Examen Historicum,* continuing, among other things, a violent attack on Fuller's *Orthodox Remains.*
or a defence of Arminianism; History of the Reformation of the Church of England; and Erius Redivivus, or the History of the Presbyterians.

HEYE, CHRISTIAN GOTTLOB, a German scholar of great celebrity, was born at Chemnitz, in Upper Saxony, 5th September 1729. He was a poor weaver. The pastor of Chemnitz, himself very poor, got H. educated at a school in the suburbs, and afterwards sent him to Leipzig university, but forgot to give him money for his support; he suffered, as were some of his contemporaries, but his endurance was heroic. In 1753, he obtained the situation of under-clerk in the Brühl library at Dresden. While in this humble office, he prepared an edition of Tibullus, which saw the light in 1755, and happening to fall into the hands of Rhunken of Leyden, excited the admiration of that scholar. In 1756, unfortunately for H., the Seven Years' War broke out. Frederick the Great marched against the French, and burned, among other things, the Brühl library, but not before his agent had copied some works, from a codex there, the Enchiridion of Epictetus. For some time he led a precarious life, being often without employment, and without bread. In 1761, he renewed, and supposed it would be best he could by writing for the booksellers; and in 1763, on the death of Gessner, professor of rhetoric at Göttingen, he was appointed his successor on the recommendation of Rhunken of Leyden (who had not forgotten his editions of Tibullus and Epictetus). This closed his period of misfortune. The rest of his long life was spent in peace and comfort and professorial activity. He died 12th July 1812.

The principal works of H. Besides those mentioned, are his editions of Virgil (1767, 6th ed. 1803), Pindar (1774), Apollonius (1787), Phily (1790), Conon and Parthenius (1798), and Homer (6 vols. 1802; 2d ed. 1804). He also executed 'almost a cart-load of translations,' besides 'some ten or twelve thick volumes of Prologues, Epilogues, and Essays,' of which six volumes were published separately under the title of Opera Academica (Göttingen, 1785-1812); and finally, about 7500 volumes of books in the Göttingen Collection of Authors, of which he was director from 1770. In addition to this herculean work, he had a private class or Seminum for the advanced study of philology and classical antiquity, from which he sent forth, in the course of his life, no less than thirty graduates.

Compare the Life of Heyne by his son-in-law, Ludwig Heeren (Göttingen, 1813), and Carlyle's essay on the same.

HEZEKIAH (Heb. Hiskiah, Yehshikaya, 'May Jehovah strengthen him'), king of Judah, son and successor of Ahaz, reigned from 728 [727] to 696 [697] B.C. 'There was none like him among all the kings of Judah,' is the praise bestowed upon him in 2 Kings xxviii. 5, and scarcely less flattering is the account preserved of this monarch in 2 Chron. xxix. From the moment that, at the early age of twenty, he mounted the throne, his efforts seemed chiefly to have been directed towards the abolition of the idolatry which reigned paramount in the land, and the restoration of the worship of Jehovah to its pristine purity and glory. The temple was reopened, the Priests and Levites whose genealogies had proved correct had their ancient revenues assigned to them, and recommended the daily service; and the first passover which fell in H.'s reign, was, albeit a month after the appointed season, celebrated with almost unparalleled pomp for full fourteen days, amidst a vast concourse of people, not only of Judah, but even of Israel. Victorious in the wars he waged with the Philistines, and relying on an Egyptian alliance, into which he had entered against the advice of Isaiah. H. dared also to withhold the annual tribute imposed by Shalmanasar in the days of his father: whereupon, as would appear from cuneiform records, Sargon, Shalmanasar's successor, invaded Judah, but without success. When, however, Sargon's successor, Sennacherib, on his way to Egypt and Ethiopia, had already seized Lachish, or, according to Chron. and Isaiah, 'all the fortresses of Judah, nothing remained for H. but to ask for a year's reprieve, and offer a bull and a talent of gold; Sennacherib might deem fit to impose. Sennacherib took an enormous sum in silver and gold, for which the sacred treasury and the very doors of the temple were laid open; and the ancient historians have been led to attribute to him alone a stratagem to convince the conqueror of the poverty of the royal coffers. It is a moot-point whether Sennacherib, after having received the money intended to procure the peace, treacherously marched upon Jerusalem at once, or whether he continued his march to Egypt, and being beaten there before Pelusium, besieged Jerusalem on his return—which would be equal to a second invasion. H.'s efforts to render his capital impregnable were futile. Suddenly, however, the Angel of the Lord appeared, and there was an earthquake, a sudden attack by Tirhaka, or the Simojew slaughter during one single night 180,000 men in the Assyrian camp; and Sennacherib, it appears, was dragged to his death. Whether H.'s illness—'Shecin,' his sufferings, according to some, or the plague, as others understand—stood what—took place before or after Sennacherib's invasion, is not fully established as yet; certain it is, that after his miraculous recovery indicated to him by the retrograde movements of the dawn, he, among other visits of congratulation, also received that of the ambassadors of Merodach Baladon (Mardouknapades), king of Babylon. The latter—as would seem to be contribution—perhaps only a flattery—was at that time likewise tributary to Assyria, and sent the embassy with a view to securing H.'s co-operation against the common enemy. H., imprudently enough, made a great display of his treasures, his machine, and army, but so far from impressing the messengers with his greatness, he only kindled in Merodach Baladon the desire to possess himself of all these things; and the latter Babylonian invasion ending in the fall of the captivity, is undoubtedly to be traced back to this act of vanity on the part of Hezekiah.

The remainder of H.'s life was passed in profound peace and prosperity, so that he was enabled to turn his attention to the internal development of the resources of the country, and the fortification of its towns. He collected great treasures and executed many highly useful works, among which the architecture of Jerusalem take a foremost place. His was also the golden age of prophetic poetry. Besides Isaiah, there lived in his time the prophets Micah and Nahum. From a passage in Prov. xxv. 1, it would also appear that he founded a society of writers, who collected and arranged the ancient documents of Hebrew literature, more especially the Proverbs attributed to Solomon. H. himself was a poet of no mean order; witness the hymn he composed after his recovery. H. died at the age of 54 years, in the 28th year of his reign, and was succeeded by his son Manasseh.

The Mishna (Pes. 4, 9) enumerates three things for which H. is to be praised, and three things for which he is to be blamed. The unmerited blessings of his father, on account of his wickedness; the breaking of the brass serpent of Moses, which had become an object of idolatry; and the hiding of a book of medicines—some superstitious work. These are the threats of God, which were issued from the mouth of the temple, to pay the tribute to Sennacherib;
HIBERNATION—HIBISCUS.

The storage up of the upper Giloh during the siege of Jerusalem; and his postponing the first Persian month (see above), are his three Wick words.

HIBERNATION (from hibernare, to pass the winter) is the term applied by naturalists to express a peculiar condition of sleep in which certain animals—especially bears and rodents—pass the winter or other season. It is not very clearly known to what extent hibernation prevails in the animal kingdom. The bats, the hedgehog, and the dormouse are the animals which in this country present the most striking examples of this phenomenon.

The term hibernation is not a good one, because summer heat produces in some animals a very similar condition to that which winter cold produces in others; and hence the Germans use the words Winterschlauf (winter sleep) and Sommerschlauf (summer sleep) to express the two similar if not identical conditions.

The following are the most marked peculiarities presented by bats, hedgehogs, and dormice, when in a state of perfect hibernation:—The respiration is very nearly suspended, as is shewn (1), by the absence of all detectable respiratory acts; (2), by the almost entire absence of any change in the air in the place in which the animal is placed during the investigation; (3), by the subsidence of the temperature to that of the atmosphere; and (4), by the capability of supporting, for a great length of time, the entire privation of air. The circulation is reduced to an extreme degree of slowness. In an observation made by Dr Marshall Hall, the heart of a bat was observed to beat only twenty-eight times in the minute. The excreta are very scanty. The bat is observed to have scarcely any excretor during its continued lethargy.

In regard to the nervous system, sensation and volition are quiescent, but reflex or exoto-motory actions are very readily produced. The slightest touch applied to one of the spines of a hedgehog, or the merest shake given to a bat, induces one or two inspiratory movements. Dr Marshall Hall made the important discovery that, while the respiration is almost totally suspended, the muscular irritability is proportionally augmented. All hibernating animals instinctively adopt various measures to secure themselves, during the lethargic period, from sources of disturbance and excitement. They choose slighted and sheltered situations, burrows, crevices, or nests. Some form themselves nests; others congregate together in large numbers. The hedgehog and dormouse roll themselves up into a ball; the bats group together in clusters, with the head downwards, and in some species the wings are spread, so that each individual embraces and shelters its neighbour. Revivescence is due partly to the return of warmth, but mainly in all probability, to the calls of hunger. The return of the respiration and animal heat to the normal standard is very gradual.

The physiological use of hibernation is doubtless to enable certain animals to avoid the consequences of severe winter cold, and (especially in the case of the insectivorous animals) the deprivation of food. Before the period of hibernation, a large amount of fat is accumulated in the organism, and this fat constitutes the fuel on which the animal lives and supports its comparatively trifling heat during the winter. The other tissues suffer to a less extent, and the total loss of weight is sometimes nearly 40 per cent.—a proportion fully as great as that which is usually sustained in death by starvation. The extent of this phenomena of hibernation, the reader is referred to Barkow, Der Winterschlauf nach seiner Erscheinungen im Tierreich dargestellt (Berlin, 1846).

HIBERNIA, IBERNA, IVERNIA, also IERNE, names by which Ireland is designated in the classical writers. The first mention of Ireland in ancient times occurs in a poem on the Argonautic expedition, attributed to the mythical Orpheus, and perhaps as early as the time of the first Iarini. Aristotle speaks of two

HIBISCUS, a genus of plants of the natural order Malvaceae, the type of a tribe or sub-order in the classical writers. H. cannabinum, constitutes a native of Asia and Europe, and the few others almost wholly cultivated in the temperate and tropical climates. It is a native of Syria, and Carmola, has long been in cultivation as an ornamental shrub, and proves sufficiently hardy in many parts of the present hothouse plants. The characteristic mucilaginous and fibrous properties of the Malvaceae are very strongly developed in this tribe. The fruit of H. cannabinum (or Abelmoschus esculentus) so abunds in mucilage, that it is much used in the north-west of India for clarifying sugar. The fruit of H. esculentus (or Abelmoschus esculentus) is in general use both in the East and West Indies for thickening soups, and otherwise as an article of food. It is called Gombo, Gombo, and Ocho in the West Indian; Bandakai, Kam-turai, and Denroos in different parts of India; and Bamba in the west of Africa; if indeed the East Indian H. lonyfolius, or the species of our own Indies, is not the true H. cannabinum, as some suppose. It is a native of the south of Europe, and is used in an unripe state. It is generally much esteemed, but is disdained by some on account of its viscidity. It enters, as an important ingredient, into the pepper-pot of the West Indies. The ripe seeds are sometimes used in soups as barley. The bark of H. thoconus—a tree of twenty feet high, with a very thick bole—so abounds in mucilage, that by chewing it the natives of the South Sea Islands obtain nourishment in times of scarcity. This tree, the Bola of Bengal—supposed to be the same with the Molok or Molot of the West Indies (H. arborea)—is one of the most abundant trees of the South Sea Islands; and the wood, being light, tough, and durable, is much used for may purposes. The bark is very fibrous, and cordage and matting are made of the fibre in various tropical countries. Many other species yield fibres, some of them of inferior quality, to which are used in different countries; but the most important in this respect is H. cannabinus, the American Hemp and Deckeane Hemp of W. Veren India,
HICCUP.—HICORUM.

called Pauwadong at Madras, and Malwa Paut in Bengal; a plant very generally cultivated in all parts of India, although nowhere to a great extent. It is an annual herbaceous plant, having a straight or branching stem, 3 to 7 feet high. The fibre is not so strong as hemp, and is useful only for ropes and coarse fabrics. It has been suggested that man of this species of H. might be found valuable for the manufacture of paper.—H. Subolaris is very generally cultivated in warm countries, on account of its calyx, which, when the fruit ripens, becomes fleshy, and acquires a very pleasant acidity. It is much used for making tarts and jelly, and a decoction of it, sweetened and fermented, affords a refreshing beverage, well known in the West Indies as Sorrel Cordial, the plant being called Red Sorrel. H. Actinophora (or Abietinaria moxchatia), sometimes called Mox Seed, another plant common in widely separated tropical countries, is cultivated for its seeds, which have a fragrance between that of musk and that of amber. They are much used by perfumers, and are called Ambret or Graines d’Abret. In Egypt and Arabia they are mixed with coffee, and stimulant and stomachic qualities are ascribed to them. The petals of the flowers are astringent, and are used by the Chinese to stain their eyebrows and their shoes black.

HICCUP, or HICCOUGH, consists of sudden short convulsive inspirations, attended with a peculiar sound produced in the larynx, and immediately followed by expiration. The movements concerned in the production of hiccup are a spasmodic contraction of the diaphragm, and a certain degree of constriction in the glottis, which occasions the peculiar sound, and limits the amount of air inspired. These convulsive inspirations commonly occur in paroxysms, and succeed each other at intervals of a few seconds. The paroxysm may last only a few minutes, or may extend to hours or days; in the last-named case, it may be dangerous to life, from the exhaustion which it causes, but usually it merely excites a feeling of uneasiness or slight pain about the region of the diaphragm.

A debilitated state of the system predisposes to hiccup. In those predisposed to it, any gastric derangement, as emesis, or over-dissipation of the stomach, the ingestion of cold water, excessive acidity, &c., will provoke it. Certain diseases are frequently attended by hiccup. When this state is slight, it may often be stopped by making a very full inspiration, and then holding the breath as long as possible, the diaphragm being thus held in a state of voluntary contraction. Strong pressure, as a belt tightly drawn round the waist, will sometimes give relief. In more obstinate cases, aromatic spirit of ammonia, camphor, musk, &c., may be resorted to. A combination of camphor and chloroform, and the frequent swallowing of small rounded pieces of ice, are perhaps the most efficient remedies.

HICKES, George, D.D., an eminent English divine and philologist, was born at Newsham, Yorkshire, June 26, 1642. He studied at Oxford, and in 1664 was elected fellow of Lincoln College. In 1665 he passed M.A., and in 1666 was admitted to orders. In 1676 he became chaplain to John, Duke of Lauderdale, whom, in 1677, he accompanied to Edinburgh. In 1678 he received the degree of D.D. from the University of Glasgow, and in 1679 from that of Oxford. In 1682 he was appointed to the king’s chaplaincy, and the following year made dean of Worcester. Refusing at the revolution to take the oaths to King William III., he was deprived of all his benefices. In 1693 he was sent with a list of the nonjurors clergy to the exiled king at St. Germain, and in 1694 was consecrated by a prelate of his own party suffragan bishop of Thetford. His publications in controversial and practical divinity are numerous. His greatest work, entitled Theaurus Grammatico-Theologicus et Archæologicus Linguarum Veterum Septemdecim, was published in 1705, 3 vols. fol. He died December 15, 1715.

HICKORY (Carya), a genus of trees formerly included among Walnuts (Juglans). The Hickories are exclusively North American. They are large and beautiful trees, attaining a height of 70 to 80 feet, with pinnate leaves. The timber of all of them is very heavy, strong, and tenacious, but decays speedily when exposed to heat and moisture, and is said to be peculiarly liable to injury from worms. Great quantities of H. are used to make hoops for casks. It is much used for handspikes. Musket-stocks, shafts of carriages, handles of whips, large screws, &c., are made of it. It is greatly esteemed for fuel. The nuts of some of the species are excellent eating, and much resemble walnuts. —C. alba, the SHELL-BARK or SHAG-BARK H., so called from its shaggy outer bark peeling off in long narrow plates; yields the common hickory-nut of the northern parts of the United States; also known as the Kisky Thomas Nut. It abounds on Lake Erie, and in some parts of New Jersey and Pennsylvania. The trunk is slender. The leaves are often 20 inches long. The nuts are in considerable request, and are sometimes exported. The shell is thin but hard, the kernel sweet. An oil, which is used by the Indians as an article of food, is obtained from it by pounding and boiling. —C. sylvestris, the THICK SHELL-BARK H., a very similar tree, abounding in the fertile valleys of the Alleghany mountains, has a nut with a thick yelloskell shell, which is often brought to market in America, under the names of Springfield Nut and Gloucester Nut. —C. oligomeris, yields the PECAN or PECAN NUT, sometimes called the Illinois Nut. —Other species yield the MOCKER NUT, PIG NUT, and BITTER NUT.

HICKS, Elias, a celebrated American preacher of the Society of Friends, was born at Hempstead, Long Island, March 19, 1748. His gifts were early recognized by the society, and at the age of 27 he had become a well known preacher, and for many years travelled through the States and Canada. His unitarianism, or denial of the divinity of Christ and a vicarious atonement, brought him into disfavour with orthodox Friends; but he preached his own views with perseverance, and at the age of 80 still travelled and preached. The result of his labours was a schism of the society into two divisions, popularly known as Orthodox and Hicksite Quakers. He died at Jericho, Long Island, February 27, 1830. See Elias H.’s Journal of his Life and Labours (Philadelphia, 1828).

HIDALGO (Spanish, in Portuguese, Fidalgo; a word derived from fido del gozo, ‘son of a Goth,’ implying purity of descent, and by others from hijo de alguno, ‘son of somebody’) is the title of a class of the lower nobility in Spain.

HIERA PICRA, or HOLY BITTER, once a highly popular remedy, and still much employed in domestic medicine, and in veterinary practice, is composed of four parts of powdered aloe and one part of canella. It is identical with the official preparation known as Pulvis Aloes cum Canellid. The principal objection to its use as a purgative medicine is, that the nauseous taste of the aloe is not concealed by the canella; and that, like aloetic preparations generally, it is liable to cause irritation of the lower part of the intestinal canal.

HIERACIUM. See HAWKWEED.
HIERARCHY—HIEROCLES.

HIERARCHY (Gr. hieros, sacred, and arko, to govern), the name used by theological writers to designate the whole sacred governing and ministering body in the church, distributed according to its several gradations. The word, in its strict acceptance, is, of course, only applicable to the Roman Catholic Church, and to those Christian communities which retain the prelatical form of church government, or at least the distinctions of ecclesiastical order and gradation. In considering the hierarchy of the Catholic Church, it is necessary to bear in mind the well-known distinction of order and of jurisdiction. I. Considered under the head of order, the hierarchy embraces all the various orders or classes of sacred ministers to whom has been assigned the duty of directing the public worship, administering the sacraments, and discharging the various other offices connected with the preaching of the gospel; and these are of two kinds—the orders directly instituted by divine authority, and those established by ecclesiastical ordinance. Theologians commonly distinguish a hierarchy of divine right, and a hierarchy of ecclesiastical right. (1.) The first includes the three ranks of bishops, priests, and deacons. The hierarchy of right, as understood by the apostles, to have inherited the integrity of the Christian priesthood. The order of episcopate, however, is not believed to be a distinct order from that of priesthood, but only a fuller and entirely unrestriced exercise of the power of the order of the apostles, that regards what Catholics believe to be the Christian sacrifice of the eucharist, they hold that the priest possesses the same powers of order with the bishop; but he cannot consecrate the sacrament of orders, nor can he validly exercise the power of absolving in the sacrament of penance without the approbation of the bishop. The office of deacons is, to serve as helpmates of the priests and bishops, especially in the administration of the eucharist and baptism, and in the relief of the material as well as the spiritual necessities of the faithful (Acts vi. 1, and foll.). (2.) To the three ranks thus primitively instituted, several others have been added by ecclesiastical ordinance. See Orders, Minor. II. The hierarchy of jurisdiction directly regards, and is founded upon, the government of the church, and it comprises not only all the successive degrees of ecclesiastical authority derived from the greater or lesser government of the several bodies within which such governing authority is limited—beginning with the pope as primate of the universal church, and extending to the patriarchs as ruling their several patriarchates, the primates in the several kingdoms as national churches, and the metropolitan or archbishops within their respective provinces—but also, although less properly, the ecclesiastical grades which, although ecclesiastical jurisdiction may be attached to them, are more directly honorary in their nature, as those of the cardinalate, the archipresbyterate, and the archdiaconate.

In the Anglican Church, with the office of the episcopate, the theory of a hierarchical gradation of rank and of authority has been retained. The Anglican hierarchy comprises bishops, priests, and deacons. In the Scottish Church it is of course unknown, as it is in the greater number of the foreign Protestant churches; while those Lutheran communities which have retained or have revived the title of bishop, concede little to the office which can be considered as imparting to the distincting of grades in the ministry which it imports a strict hierarchic character. The Lutheran bishop is little beyond his brother-ministers, except the right to bear certain insignia, and the first place in the consistories.

In the well-known work, The Celestial Hierarchy, falsely ascribed to Dionysius the Areopagite, the hierarchy includes Christ as its head, and the various orders of angels as his ministering spirits.

HIERATIC WRITING. See Hieroglyphics.

HIERO I., king of Syracuse, succeeded his brother Gelon in the year 478 B.C. The most important event of his reign was the naval victory gained by his fleet and that of the Cumans over the Etruscans in 474, which deprived the latter of their supremacy in the Tyrhenian Sea. In the year 472, Thrasaenus, who had meanwhile become tyrant of the country, in Cosyrii, was conquered by Hiero. H. himself was violent and rapacious, far inferior in character to his brother Gelon. His love of poetry, and the manner in which he entertained poets like Simonides, Echylus, Bacchylides, and Pindar at his court, have perhaps caused him to be overestimated.

HIERO II., king of Syracuse (269—214 B.C.), was the son of a noble Syracusan named Hierocles. During the troubles which prevailed in Sicily, after the retreat of King Pyrrhus, 275 B.C., H. greatly distinguished himself, and was first appointed eleventh, and then twelfth, of the ten Carthaginians in besieging Messana, which had surrendered to the Romans, but he was beaten by Appius Claudius the Roman consul, and obliged to retire to Syracuse, where he lived; a place of security. In 263, seeing himself threatened by a large army under Manius Valerius Maximus, he concluded a peace with the Romans for fifteen years, during which he proved so faithful to his engagement that in 248 peace was permanently established. H. himself visited Rome in 237, on which occasion he presented the Roman people with 200,000 bushels of corn. In the second Punic War he likewise proved himself the faithful ally of the Romans, and supported them with money and troops, especially after their defeat at the lake of Trasimene, when the golden statues of the goddess of Victory, weighing 320 pounds, which he sent to Rome, were welcomed as a good omen. He died about the year 216, in the 92nd year of his age. His son Gelon having died before him, he was succeeded by his grandson Hieronymus. H., by his clemency, wisdom, and simplicity, had gained the affections of the Syracusans, who refused on several occasions to accept his resignation of the kingly office. He devoted great attention to the improvement of agriculture, and his laws respecting the tithe of corn, &c. (Leyes Hieron), were still in force in Cicero's time. He was afterwards to be considered a patron of the arts, particularly architecture. In these pursuits, as well as in the construction of war-like machines, he was assisted by his friend and relative Archimedes.

HIEROCLES, a common name among the Greeks. The most celebrated of this name was H., the Neo-Platonist, who lived at Alexandria about the middle of the 5th c., and enjoyed a great reputation. He is usually reckoned the author of a commentary on the golden verses of Pythagoras, of which the best edition is that by Warren (London, 1742). Of H.'s history we know nothing. His most celebrated works are—On Providence, Fate, and the Harmony between the Divine Government and Man's Free Will; of which there remain preserved by Photius, and published by Morelli (Paris, 1593 and 1597). Another ethical work of his, On Justice, Reverence of the Gods, and the Domestic and Social Virtues, is known to us from a number of extracts in Stobaeus. There is also a work called Astrod (a collection of jests and ludicrous stories) attributed to him, but it is now believed to belong to a much later age than that of Hierocles. The and the previous works are contained in Pearson and
HIEROGLYPHICS

Needham's Commentary on Pythagoras (Cambridge, 1709).

HIEROGLYPHICS (literally meaning sacred sculptures), a term applied to those representations of natural or artificial objects used to express language, especially those which the ancient Egyptians and Mexicans employed for that purpose.

The term hieroglyph, would, however, be more correctly applied to these figures. The number of those used by the Egyptians is not exactly known; it is about 7500, probably about 5000, and by their means they were enabled to express all the ideas required with correctness, clearness, and facility. They consist of representations of celestial bodies, the human form and its parts in various attitudes, animals, fishes, reptiles, works of art and attire, and fantastic forms. These were either engraved in relief, or sunk below the surface on the public monuments and objects of hard materials suited for the glyptic art, or else traced in outline with a reed pen on papyrus, wood, slices of stone, and other objects. The scribe, indeed, wrote from a palette or can one called pes, with pens, kahh, from two little ink-holes in the palette, containing a little opaque white or black ink. The hieroglyphs on the monuments are sometimes sculptured and plain; at others, decorated with colours, either one simple tone for all the hieroglyphs, which are then called monochrome; or else ornamented with a variety of colours, and then called polychrome; and those painted on coffins and other objects are often first traced out, and then coloured in. In the papyrus and some few inferior materials, they are simply sketched in outline, and are called linear hieroglyphs. The hieroglyphs are arranged in perpendicular columns, separated by lines, or in horizontal, or distributed in a spindled manner in the area of the picture to which they refer. Sometimes all these modes of arrangement are found together. One peculiarity is at once discernible, that all the animals and representations face in the same direction when they are combined into a text; and when mixed up with reliefs and scenes, they usually face in the direction of the figures to which they are attached. When thus arranged, the reliefs and hieroglyphs resemble a MS., every letter of which should also be an illumination, and they produce a gay and agreeable impression on the spectator. They are written very square, the spaces are neatly and carefully packed, so as to leave no naked appearance of background. Generally, they are to be read from the direction in which they face, and are allowed to succeed in the same succession, but many exceptions occur, in which they follow the reverse order, whether written horizontally or vertically, and this at all periods.

The hieroglyphs, in their nature, are divided into two great classes—ideographs, or those which represent ideas; and phonetics, or those which express sounds. No doubt, at the first commencement of the language, ideographs only were employed; but the earliest known monuments, which ascend to the 3rd dynasty above 2000 years B.C., are filled with phonetic hieroglyphs, showing that at that early period the principle of writing sounds had been completely developed. These hieroglyphs, at the most developed period of the language, comprised about one-third of the texts.

The ideographs are divided into two classes—the simple ideographs, or those which express one idea; and the ink of animal claws, and also, to a still greater extent, many. In all instances, these ideographs are occasionally found preceded by phonetic groups, which give the sound of the idea they are intended to express in the written language; the simple ideographs being found only preceded by one group; while the determinatives are preceded by many. The pure ideographs are of various classes: first, those representing the object directly, as ﬀ, a dog, ubur, to express the idea dog; secondly, those metaphorically conveying the required meaning, as ﬀ, a woman beating a tambourine to indicate 'joy,' in which the action indicates the effect produced; thirdly, that in which the attribute is expressed by the figure of some object possessing it, as ﬀ, a jallak, to indicate 'cunning' or 'craft'; a ﬀ, a flaming censor, to signify 'incense.' Or the direct action was often represented; as a bird fishing ﬀ, to express the idea of fishing in general. Such a mode of depicting ideas in detail was only suited for elaborate monuments; and the number of ideographs required to express all ideas, would have been so many as to have overwhelmed the memory of the lexicographer, and to have obscured the comprehension of the reader. In order, therefore, to reduce the number of ideographs, a certain number of these hieroglyphs were used to express more ideas than one in the principal classes of thought. Thus, ﬀ, a seated man, originally employed to signify man, was applied to all relationships, functions, and offices of men, as, isf, father; ass, brother; mer, governor; hentuer, priest; lath, governor; the special meaning of each conveyed being shown by the phonetic groups which preceded it. In the same way, all beasts or objects made of leather were expressed by a skin, ﬀ; all precious stones or objects made of the same by a ring, ﬀ; all actions of locomotion by ﬀ, two legs in the act of walking; and all actions in which the arms were used by ﬀ, an arm holding a stick. The number of these signs may be computed at about 175, and they resemble in their use those of the Assyrian cuneiform, in which, although to a more limited extent, the leading classes of thought were determined by a character prefixed to the phonetic group giving the particular idea. Thus, in the Assyrian, all names of men are preceded by ﬀ, a single upright wedge; all countries by ﬀ, three wedges disposed obliquely; and names of horned cattle by the group of five wedges ﬀ.

In the Egyptian system, however, the determinatives are always placed after the phonetic groups, and are more numerous. The Chinese system of writing approaches still more closely to the Egyptian, 242 radicals, as they are called, but really determinatives, being placed after other groups and symbols, which indicate the special idea intended. In this last language, the radicals are generally placed to the left, as ﬀ, hau, 'good,' in which the radical is ﬀ, neu, 'a woman,' except in those instances in which they enclose the phonetic or special groups. In the Egyptian hieroglyphs, every word not expressing an abstract idea, as the verb to be, or the grammatical forms, and pronouns, is accompanied by its determinative, and is incomplete without it. The genius of the writing is that the phonetics and ideographs mutually explain each other. Sometimes, indeed, by a kind of redundant pleasure, the use determined by the ideograph, after the special ideographs, as ﬀ, the three rings of metal after the cape used to express gold and silver; ﬀ, the three flowers after the lily, to signify
HEROGLYPHICS.

lily, and, skin, the skin after the goat, to mean goat. The phonetic portion of the hieroglyphs consists, at the best period of writing, of a limited number of signs, about 130, employed as a syllabarium; and although the term alphabet has been often used in speaking of the phonetic hieroglyphs, nothing of the nature of a pure alphabet existed till a later period, when the Phenicians invented a purely alphabetic system, suppressing the vowels, which the Greeks still further improved by reintroducing them into their graphic system, and so brought to perfection the invaluable invention of alphabetic writing, at once concise, comprehensive, and complete. But the Egyptian hieroglyphs comprise two classes of syllables—those ending with vowels, or the so-called alphabetic, and those ending with consonants; or, in other words, of monosyllables and polysyllables. As the monosyllables enter into the composition of the polysyllabic groups, it is evident that they are older than the bilateral or dissyllabic hieroglyphs. The spoken language seems, in fact, to have originally consisted of monosyllables, which were subsequently enriched by agglomeration, and combined into bilateral and triliteral roots. Several of these monosyllabic words have descended from the ancient language to the Coptic, as ak, a lamb; ou, a cow; man, a lion; ru, the sun; pt, the heaven. Numerous words of this class may still be traced as the roots of the more ancient language, but it is obvious that only a few of the most manageable could be selected for the combined purposes of sound and writing. In some instances, two or more seem to have been selected for the same sounds, in order to suit the style of writing, horizontal or vertical signs being required for the careful packing of the groups in the texts. Now, it will be necessary to bear in mind that each of these hieroglyphs of the first phonetic division represents a monosyllable, of which it represents the whole by itself considered as the initial, but that it was always capable of having the vowel hieroglyph which followed the initial placed after it, and that in the hieratic or cursive Egyptian writing, this was generally the case, in order to distinguish the signs. This final vowel is, however, generally omitted in hieroglyphic texts, and is said to be inherent, or ought to be pronounced in the first hieroglyph. The alphabetic syllabarium is as follows:

This comprises all the signs which may be considered alphabetic in their nature, at the best period, or from the 4th to the 21st dynasty, when a revolution took place in the mode of writing, and about 90 additional signs, taken from the ideographs and syllables, were added to the preceding alphabetic, and used indiscriminately—not, indeed, at once, but by gradual introductions, from the 21st dynasty till the 21st c. a. D. Nor are all the signs of the preceding alphabet of equal antiquity, or as much used as others. As to the inherent nature of the vowels, it may be observed that A, the commonest, is often written with its complement sa after it, as and that U is indifferently expressed with a, as Ah, Ha. Of the three forms of the A, the first expresses the aspirate, the second the nasal, and the third the soft breathing. Besides, too, their final complement, the initial sound, especially of consounds, probably of those newly introduced into the system, was placed before them, to explain their use. Thus was often written Nu, preceded by N, and followed by x, as others in the like manner. The consideration of the signs that precede and follow after, indeed determines the sonal value of certain hieroglyphics which are thus encased and explained by other phonetics. The syllables are constructed on the same plan. They consist of an initial hieroglyph, which is capable of expressing by itself the whole syllable, as Am, Her, but which take after them their inherent consonant or complement, as Ha.
Hieroglyphics.

AM, \(\text{H} \text{E} \text{R} \), and are sometimes preceded by their initial complement, as \( \text{H} \text{E} \text{R} \text{AM} \), \( \text{H} \text{E} \text{R} \text{AM} \text{O} \text{N} \), \( \text{H} \text{E} \text{R} \text{AM} \text{O} \text{N} \text{O} \text{S} \). These are more numerous than the alphabetic-syllabic class, and are as commonly used in the texts. The language, or rather the literature of this time, consisted of a certain ideographic character, which it retained, certain words being only written by certain syllables, and the use of the two syllabaries was by no means promiscuous, the examples of different modes of grouping the same word being abnormal, and referable only to long intervals of time. For although several hundred papyri exist in the museums of Europe, and no two are written precisely alike, yet the greatest differences will be observable in those which are similar texts, written at long intervals of time from each other. Nevertheless, some latitude prevails in the writing of certain words and proper names, and those hieroglyphs which appear in the corresponding places of others are called homophones. Sometimes the same proper name is represented by six different groups of hieroglyphics, yet they could only have been pronounced in one way, as they represent the same name, and the different hieroglyphs are consequently only interchangeable to express the same sounds.

The language of the hieroglyphics is nearest to the Coptic, the form which it assumed about the 3d c. B.C., when the Greek alphabet, reinforced by letters borrowed from the demotic or popular cursive hand of the period, superseded the demotic and hieroglyphic mode of writing. This language, extinct only as spoken about a century and a half ago (see Coptic), differs considerably from the monumental texts, having been corrupted by the introduction of Greek, Latin, and Arabic words, but this contains, as its base, the old language of the country—a tongue analogous in some respects to the Semitic dialects, but in others of a construction which may be called Hamitic, or allied to the African. The great peculiarity of the hieroglyphic language is, that the verbal root both of the nouns, adjectival, and verbal remains unchanged, and that the dual and plural are made by postixes, the cases of the nouns formed by prepositions, and the tenses of the verbs by the prefixing of the declined abstract auxiliary verbs, \( \text{H} \text{E} \text{N} \), \( \text{H} \text{E} \text{N} \text{O} \text{N} \), \( \text{H} \text{E} \text{N} \text{O} \text{N} \text{O} \text{S} \), \( \text{H} \text{E} \text{N} \text{O} \text{N} \text{O} \text{S} \text{O} \text{N} \), \( \text{H} \text{E} \text{N} \text{O} \text{N} \text{O} \text{S} \text{O} \text{N} \text{O} \text{S} \), \( \text{H} \text{E} \text{N} \text{O} \text{N} \text{O} \text{S} \text{O} \text{N} \text{O} \text{S} \text{O} \text{N} \), \( \text{H} \text{E} \text{N} \text{O} \text{N} \text{O} \text{S} \text{O} \text{N} \text{O} \text{S} \text{O} \text{N} \text{O} \text{S} \), \( \text{H} \text{E} \text{N} \text{O} \text{N} \text{O} \text{S} \text{O} \text{N} \text{O} \text{S} \text{O} \text{N} \text{O} \text{S} \text{O} \text{N} \text{O} \text{S} \). The prepositions are either detached and prefixed or affixed, and the prepositions are either simple or compound; many remarkable forms of the last class existing in the language. There is a great vagueness in their employment, and their meaning is often abnormal, and only defined by the context.

Considered as the most ancient written language, the hieroglyphs throw great light upon comparative philology, the relative antiquity of various words and locations, the general construction of language itself, and the development of picture-writing into the abstract ciphers of sound, called letters. A great portion of the words are similar to the Semitic, either directly or indirectly: thus \( \text{H} \text{E} \text{R} \text{E} \text{M} \), the sea, is like the Hebrew \( \text{Y} \text{E} \text{M} \); \( \text{K} \text{E} \text{F} \), an ape, like \( \text{O} \text{F} \). The majority are, of course, purely Coptic; but at the period of the 19th dynasty, or about 1300 B.C., many Hebrew, Syriac, and Aramaic words were introduced into the language by the progress of the Egyptian arms to the East, and such words as \( \text{B} \text{O} \text{T} \text{H} \), \( \text{B} \text{O} \text{T} \text{H} \text{E} \text{M} \), \( \text{T} \text{O} \text{R} \text{O} \text{M} \), \( \text{T} \text{O} \text{R} \text{O} \text{M} \text{O} \text{N} \), \( \text{T} \text{O} \text{R} \text{O} \text{M} \text{O} \text{N} \text{O} \text{S} \), \( \text{T} \text{O} \text{R} \text{O} \text{M} \text{O} \text{N} \text{O} \text{S} \text{O} \text{N} \text{O} \text{S} \), \( \text{T} \text{O} \text{R} \text{O} \text{M} \text{O} \text{N} \text{O} \text{S} \text{O} \text{N} \text{O} \text{S} \text{O} \text{N} \text{O} \text{S} \). These are, however, rare and few in number compared to the body of the language. Many other words appear to be Indo-Germanic. The literature will be found under the word Papyrus.

The invention of hieroglyphs, called \( \text{N} \text{E} \text{T} \text{E} \text{R} \text{K} \text{A} \text{R} \), or \'divine words,' was attributed to the god Thoth, the Egyptian Logos, who is repeatedly called the scribe of the gods, and lord of the hieroglyphs. Pliny attributes their invention to Memnon. The Egyptian hieroglyphs, or hieratic, or Hermic or Hermetic, on account of its supposed divine origin, and the knowledge of hieroglyphs was, to a certain extent, a mystery to the ignorant, although considerably employed by the semicircular and instructed classes. To foreign nations, the hieroglyphs always remained so, although Moses is supposed to have been versed in the knowledge of them (Philo, Vita Mosis); but Joseph is described as conversing with his brethren through interpreters, and does not appear to allude to hieroglyphic writing. The Greeks, who had settled on the coast as early as the 6th c. B.C., do not appear to have possessed more than a colloquial knowledge of the language, and although Solon, 538 B.C., is said to have studied Egyptian doctrines at Sebennytus and Heliopolis, and the doctrines of Pythagoras are said to have been derived from Egypt, these could only have been derived from hieroglyphic knowledge from interpretations of hieroglyphic writings. Heracleides (521 B.C.) and Herodotus (456 B.C.), who visited Egypt in their travels, obtained from similar sources the information they have given in their works. The Greeks did not put much stock in hieroglyphs, and began to pay attention to the language and history of their subjects, and Eratosthenes, the keeper of the museum at Alexandria, and Manetho, the high-priest of Sebennytus, had drawn up accounts of the national chronology and history from hieroglyphic sources. Under the Roman empire, in the reign of Augustus, one Chremonem, the keeper of the library at the Serapeum, had drawn up a dictionary of the hieroglyphics; and both theodorus and Strabo mention them, and describe their nature. Tacitus, later under the empire, gives the account of the monuments of Thebes translated by the Egyptian priests to Germanicus; but after his time, the knowledge of them beyond the works of Herodotus, was exceedingly lost, and does not reappear till the 3d and subsequent centuries A.D., when they are mentioned by Ammianus Marcellinus, who cites the translation of one of the obelisks at Rome by one Hermapiam, and by Julius Valerius, the author of the apocryphal life of Alexander, who gives that of another. Heliodorus, a novelist who flourished 400 A.D., describes a hieroglyphic letter written by Queen Candace (v. 8). The first positive information on the subject is by Clement of Alexandria (211 A.D.), who mentions the symbolical and phonetic, or, as he calls it, etiologic nature of hieroglyphics. Porphyry (304 A.D.) divides them also into etiologic or phonetic, and etiologic or symbolic. Herapolis or Horus-Apollos, who is supposed to have flourished about 500 A.D., wrote two books explanatory of the hieroglyphs, a rude, ill-assorted confusion of truth and fiction, in which are given the interpretation of many hieroglyphs, and their etiologic meaning. After this writer, all knowledge of them disappeared till the revival of letters. At the beginning of the 16th c., 1529 A.D., these symbols first attracted attention, and soon after by Kircher, a learned Jesuit, pretended to deduce them by vague etiologic notions derived from his own fancy, on the supposition that the hieroglyphs were ideographic, a theory which has been all progress, 363.
and was held in its full extent by the learned, till Zoega, at the close of the 18th c., 1787 A. D., first enumerated that the oval or cartouches contained royal names, and that the hieroglyphs, or some of them, were used to express sounds. More monuments were known, and juster ideas had begun to dawn on the European mind; and the discovery by the French, in 1799, of the so-called Rosetta Stone, and its inscription, having impressed, first, on the ideographs, secondly in demotic or choucerial (a cursive form of writing extant at the period), and thirdly in Greek, a decree of the priests of Egypt assembled in synod at Memphis, in honour of Ptolemy V., gave the first clue to the decipherment. The first attempts, indeed, were made upon the demotic text by Silvestre de Sacy with some success, but it was soon discovered that the demotic was not purely alphabetic. Under notions of the ideographic nature of the hieroglyphs prevailed till Dr Young, in 1818, first gave out the hypothesis, that the hieroglyphs were used as sounds in royal proper names. He was led to this conclusion by tracing the hieroglyphs through the cursive hieratic to the more cursive demotic; and as this last was known to be alphabetic, he deduced that the corresponding hieroglyphic signs were so. In this manner, he came to the conclusion that the first hieroglyph in the name of Ptolemy \( \left( \frac{\text{h}}{5} \text{L} 0 \text{L} \text{m} \right) \) in the Rosetta Stone (a mat) represented a P; the second (\( \text{h} \)) a T; the third (\( \text{h} \)) supposed to be superfluous; the fourth (\( \text{h} \)) a lion; the fifth and sixth, the syllable M; and seventh, the back of the seat, an S. Unaided by bicultural monuments, he essayed to decipher the names of Berenice, and altogether established the value of five hieroglyphs as letters out of two names, but was unable to proceed further. Champollion, in 1822, by means of an inscription found on an obelisk at Philae, which had at the base a Greek inscription, recognised the name of Cleopatra, and by comparison with that of Ptolemy, at once proved the purely alphabetic, not syllabic-alphabetic nature of the signs. Extending the principle, he read by its means the names of the Greek and Roman, and finally those of the native monarchs. It was soon seen that the same hieroglyphs as those used in these names were extensively used in the texts for words, and these words turned out, in most instances, to be alphabetical, or Coptic. Although the decipherment of Champollion were received by many of the learned in Europe with distrust, yet his method of research was slowly adopted by Rosellini and Salvadini in 1832, and subsequently extended methodically by Lepsius in 1837, and by Bunsen, Hincks, De Rouge, Birch, Goodwin, Chabas, and others.

The method of interpretation adopted has been strictly inductive, the value of the characters being deduced from the equation of sounds, or homophones of similar groups. The meaning of the groups or words has been determined by examining all known instances in which they occur in passages capable of being interpreted, that of the ideographs by observing the form of the symbols; many of them have been made out from the pictures which they explain, or the phonetic groups which accompany them. A careful comparison has been instituted with the written Coptic and Hebrew roots when they exist. In short, a careful principle of induction has been applied to the study of the hieroglyphs.

An attack upon the principles of hieroglyphical interpretation has recently been made by Sir G. Caucas, in his History of Ancient Egypt. This writer demurs to the premises on which the interpretation is based, and does not consider the first steps sufficiently proved, but holds that the results have been obtained by a series of vicious hypotheses, and that the Coptic by no means is the language of the ancient Egyptians. He also refutes the fact of the phonetic nature of the symbols, nor having been mentioned by the Greek writers. The inductive method of interpretation he considers unsound. The objections brought forward have, however, been incisively and uproot, fortified by linguists; the basis is considered sure from the bilingual monuments of the Rosetta Stone, obelisk of Philae, contracts, rituals, and other documents; the truth of the phonetic value of the symbols is also thought to be proved beyond a doubt, by the fact of the sounds obtained from the first sources enabling the names of Roman emperors, Ptolemies, and even many Pharaohs, to be read with facility; while the fact of the Coptic being the remains of the ancient language of the country, is proved by its corresponding with the names of Egyptian objects and persons mentioned by Herodoto and other Greek authors. The truth of the interpretation is also defended by the recent research, and the fact that these results enable the hierogists to read with ease documents and monuments newly discovered. Whatever doubt, in fact, may exist as to the minor details and more delicate shades of language, the labours of the last few years have been fully successful in establishing the principal grammatical forms, and three-fourths of the words of the old Egyptian language. The study of the hieroglyphs has been formally recognised by the local academies of Europe as a branch of Oriental learning.

The hieroglyphs stand in the same relation to the two other forms of writing the character, called hieratic and demotic, as type does to handwriting. Their use was chiefly for official inscriptions on public or private monuments, religious formulae and prayers, and rituals or hermetic books (see PAPYRUS). The most remarkable hieroglyphic inscriptions are—those in honour of Khnumheb at Beni Hassan, recording the investment of his high office; the campaigns of Ahmes against the Hyksos at El-Kab; the annals of Thothmes III. at Karnak, the campaigns of Rameses II. against the Khita, and the turn of the account of the tank for gold-washings in the reign of Seti I. and Rameses II. at Khourmis and Redeschie; the star-rising on the tomb of Rameses V.; the journey of the ark of Khons to Bakhat, in the reign of Rameses X.; the account of Cambyses and Darius, and their Moso (see PAPYRUS). In connection with the hieroglyphs are two modes of writing them, first the hieratic writing, consisting of a kind of abridged hieroglyphs. The number of these written characters is fewer than that of the hieroglyphs, the generic determination of being more employed, and the vocalic complements of the consonants being constantly written, in order to distinguish similar forms. This writing was more extensively used than the hieroglyphic, being employed for state papers, legal documents, memoranda, accounts, religious books, rituals, and all the purposes of private and public life. Books were generally written in hieratic. It commences as early as the 4th or 5th dynasty, and terminates about the 3d or 4th c. of our era. At the earliest period, it is occasionally written perpendicularly, but it was afterwards only written horizontally, and has generally portions in red ink, corresponding to our modern punctuation marks. The cursive characters and initial contents of these rolls, see PAPYRUS. Some, indeed, have supposed that the hieratic alphabet gave rise to the Phoenician, and have endeavoured to trace the latter in ancient Egyptian. Although much ingenuity has been expended in this inquiry, the precise source of Phoenician writing...
Hieronymites—High Places.

remains involved in obscurity, the principal fact being, that a syllabary existed long prior to the Phoenician alphabet, which did not reach the perfection of the Greeks, owing to the suppression of vowels. The second kind of hieroglyphic handwriting was the demotic, or so-called cursive. It was a still further reduction of the hieratic, simpler forms being used, while the complements are not used, and it approaches still nearer the alphabetic system, which retains an alphabet of 48 characters, and is less rich in the number of determinatives and ideographs than the hieratic. It is, like all cursive hands, more difficult to decipher than the hieratic. It was introduced into the Egyptian graphic system along with the demotic writing, and was used in the 26th dynasty, or the 6th c. B.C., and continued in use till the 3d c. A.D. This was the last native form of writing in Egypt, the early Christians having introduced the Greek alphabet, with a few characters borrowed from the demotic. This is very rare used for public monuments, although it appears on the Rosetta Stone; but it was universally employed for contracts, public documents, and occasionally for religious formulæ, owing to the decreasing knowledge of hieroglyphics when the last learned by beginners. With it the Greek language began to appear in public use.

Besides the Egyptian hieroglyphics, there are those of the Aztecs or Mexican, which were a kind of pure picture-writing, the names of monarchs, towns, and other things being painted by the objects which corresponded to their names. While in the hieroglyphic handwriting the events were portrayed, the number of the years of the reign of the king was indicated by placing in a line en potense in the picture the symbols of the years of the Aztec cycle, which were named after plants and animals. The Mexican hieroglyphics, in fact, consisted of conventional pictures, and they had no means of expressing grammatical form or any structural parts of a language. This mode of pure picture-writing prevailed not only in Mexico, but amongst the nations of Central America. The knowledge of these symbols has unfortunately been almost lost since the Spanish conquest, the meaning of only a few having been rescued from oblivion in the 18th c. when the great work of the Aztec Monastery was undertaken by Brugsch, and subsequently by Young, who regarded them as their founder, and the first Hierophant. The H. was required to be a man of ripe years, without any physical defect, endowed with a fine voice, and of spotless character. He was forbidden to marry, but it is not improbable that married men were likewise appointed H., and were merely prohibited from forming a second marriage. In the mysteries, the H. represented the Demiurge or creator of the universe. He alone was authorised to preserve and explain the unwritten laws, to introduce candidates into the temple at Eleusis, and gradually initiate them into the lesser and greater mysteries. On this account, he was likewise styled Mystagoigus and prophes, and no one was allowed to utter his name in the presence of an uninstructed person. At public solemnities he carried the image of the goddess, adorned with magnificent robes.

High Bailiff, is a term applied to some officers in England, who discharge ministerial duties, such as serving writs, &c., in certain liberties or franchises, exempt from the ordinary supervision of the sheriff. The term is used in contradistinction to the ordinary name of bailiff, which is now almost confined to a term of reproach, and confined chiefly to the lowest class of officers, who execute writs against debtors.

High Commission Court, a tyrannical court established by Queen Elizabeth to reform the church, abolished by 16 Ch. 1. c. 11.

High Constable. See Constable.

High Miser: See Scurr.

High Places (Heb. Bethoth), the name given in Scripture to certain places where idolatry worship was performed by the people of Israel. The practice of erecting altars on elevated situations was common in ancient times, and originated in the belief that hilltops were nearer heaven, and, therefore, the most favourable places for prayer and incense. The fathers of the Jewish nation acted in this respect just like their neighbours. Abraham, we are told, built an altar to the Lord on a mountain near Bethel. The Mosaic law, however, true to its grand aim of securing national strength and purity by a vigorous system of isolation, prohibited the practice for the future, on the ground that hilltops were nearer heaven, and, therefore, the most favourable places for prayer and incense. In spite of the remonstrance with which the high places are again and again denounced in the Pentateuch, the prohibition seems to have been
a long time in producing the desired effect—if, indeed, it ever really accomplished it. During the whole eventful period of the Judges, it was not only practically obsolete, but we actually find that both Gideon and Manoah built altars on high places by divine command (Judges, vi. 25; xii. 16—23). It also occasions much surprise to read of the violations of the injunction—among others by Samuel at Mizpeh and Bethelhem, by Saul at Gilgal, by David, by Elijah on Mount Carmel. The explanations given by the rabbis of these contradictions between the conduct of the prophets and kings of the Hebrew people, and the commands of their great lawgiver, are too absurd for mention. Whatever may be the true explanation, it is quite certain that worship in high places was almost universal in Judea, both during and after the time of Solomon. The results were such as might have been anticipated. The people erected altars not only to Jehovah but to Baal, and from worshipping in idolatrous places, proceeded to worship holes themselves. At a later period (see Books of Kings and Chronicles) a series of vigorous efforts was made by the more pious monarchs to suppress the practice, and after the time of Josiah, it seems to have been finally abandoned.

HIGH PRIEST (Hebr. Kohen haggodol, or emph. Kohen, Gr. archierous, Lat. primus pontifex, &c.), the chief of the Jewish Priesthood. His dignity was hereditary in the line of Eleazar, the son of Aaron, and many more restrictions attended it than belonged to the ordinary office of a Priest. He was only allowed to marry an intact virgin, and one of his own tribe; every impure contact even of the dead bodies of his own parents he was strictly forbidden, besides having to abstain from many other things that might cause any defilement whatever. His functions consisted principally in the general administration of the sanctuary and all that belonged to the sacred service. He alone was allowed to enter the Holy of Holies on the day of atonement, and to consult the Urim and Thummim (q. v.). No less was his costume of surpassing costliness and splendour, comprising numerous vestments in addition to those of the High-Priest. This magnificent costume, however, was laid aside by the High-Priest when, on the day of atonement, he went to perform the most awful service in the Holy of Holies: a simple garb of white linen—the funeral dress of the Hebrew people—is all he wore on that occasion. The revenues of the High-Priest were in the main the same as those of the other priests; but, according to the Talmud, he was to be richer than these; and if his own means were insufficient, he was to be provided with copulent means by his brethren, in virtue of his exalted position; the other priests never addressed the High-Priest but by Tahi Kohen Gadol, 'My Lord High-Priest.' Before the Law, however, the High-Priest was equal to any other Israelite. It is doubtful at what time the office of Segan, or vice-High-Priest, was created. The Talmud, moreover, speaks of a Mashiach Midbamah, 'Anointed for the war,' an officer who seems to have shared the dignity of the High-Priest and whose special duty it appears to have been to read the proclamation prescribed in Deut. xx. 3, in the time of war, and who may have accompanied the troops for the purposes of celebrating the service in the camp. For further historical and theological points connected with this subject, see PRIESTS, AARON, and JEWS.

HIGH SEAS, i.e., the open sea, including the whole extent of sea so far as it is not the exclusive property of any particular country. The rule of international law is, that every country bordering on the sea has the exclusive sovereignty over such sea to the extent of three miles from its shore, but all beyond, and which is not within three miles of some other country, is open or common to all countries. The part of sea within three mile distance is generally called the territorial sea of the particular country, or mare clausum. The distinction has little effect on the right of navigation, but as regards fishing it is otherwise. Thus, for example, foreign fishermen have no right to fish within three miles of the British coast without a licence from the crown, or unless some special treaty—as, for example, the French and English treaty—has laid down other arrangements.

HIGH STEWARD, a judge now always a legal peer, who is specially appointed by the crown for the trial of peers indicted for treason or felony. He is a kind of speaker or chairman of the peers, and votes with the rest. It is one of the privileges of the British peerage to be tried by the court of the high steward.

HIGH TREASON. See TREASON.

HIGHGATE, a village of England, in the county of Middlesex, is situated in the suburbs of London, five miles north-west of St. Paul's. It comprises many elegant villas, and some important beneficent institutions. On the slope of a hill below the church of H. is the North London Cemetery. The chapelery, or ecclesiastical district, has a pop. of 4,002.

HIGHLAND REGIMENTS. The origin of the first of these regiments, the 42d, has been given under the head BLACK WATCH (q. v.). The valuable services of this regiment encouraged the government to augment the force; and accordingly seven other Highland regiments have been raised from time to time—viz., the 71st, in 1777; the 72d, or Duke of Albany's Own, in the same year; the 74th, in 1787; the 78th, or Ross-shire Buffs, in 1793; the 79th; or Cameron Highlanders, in 1805; the 92d, or Gordon Highlanders, in 1766; and the 93d, or Sutherland Highlanders, in 1800. The uniform of each of these corps is the Highland dress, including a distinctive tartan. The soldier wears a coatee of scarlet, a kilt (in most, but not all, of the regiments), a plaid across the shoulders, a plaid and the other attributes of the Gaelic costume. He is an army where officers are appointed by purchase, nationality is necessarily disregarded; but these corps are those to which Scotch gentlemen most frequently attach themselves, and about one-half the officers are Scotch. Of the men, about 79 per cent. are Scotch, 11 per cent. English, and 10 per cent. Irish. The regiments are recruited in the Highlands, the depots being stationed (1862) at Stirling and Aberdeen.

HIGHLANDS, a term generally applied to the higher parts of a country, as, for example, Highlands of the Hudson, as defining a certain high and picturesque region on the river Hudson, in the state of New York; but the term has a more special application, to a particular district in Scotland. This district has no political or civil boundary. Separated by only a vague line of demarcation from the division called the Lowlands, the Scottish H. may be briefly described as that portion of the north and north-west of Scotland in which the Celtic language and manners have less or more lingered until modern times. The Highland line, as it is usually called, extends diagonally across the county of the Moray Firth from Dumbarton on the Clyde; but the mountainous part of the counties of Banff, Moray, Aberdeenshire, Kincardine, and Perth are also understood to be
HIGHNESS—HIGHWAY.

included in the designation Highlanda. Caithness might be excluded as being a generally level country; but throughout the Herbrides (q. v.) or Western Isles are included in the H., but the isles of Orkney and Shetland, though being level traversed none being more so than the eastern division of Ross-shire. The Hebrides (q. v.) or Western Isles are included in the H., but the isles of Orkney and Shetland, though being level traversed, are distinctly excluded, by reason of the Norwegian origin of the inhabitants.

The H. are full of lofty hills, some green and pastoral with tracts of heath, and others rugged and bare, varying in height from 1000 to 4000 feet, and having generally narrow valleys between, or else lakes and arms of the sea, called lochs. Besides the greater features, there are impetuous mountain torrents, picturesque ravines, and valleys or glens, in which, and on the sides of the hills, are seen the huts of the aborigines. Perhaps the most remarkable feature in the country is the line of valleys from Inverness to Fort-William, in which lies a series of navigable lochs, united by artificial channels to form the Caledonian Canal, rising up under a system of clanship, the state of society in the H. was antiquated and unsatisfactory, in a national point of view; while the country was too small for the number of inhabitants. The most striking species of traffic. The first great attempt to reform this state of affairs was the opening up of the country by roads in different directions, under the superintendence of General Wade, about 1725—1730. The next great act of improvement was the abolition of Heritable Jurisdictions (q. v.), including the ancient privileges of the heads of clan, about 1748. And lastly, not to speak of the planting of schools and churches, much was done to improve the condition of the people, and this will be evident from which a jury may infer that the owner meant to make a present to the public of the right of way, and he cannot after wards exclude the public, for the maxim holds, 'once a highway, always a highway.' The mode in which a grant of a way was made, was that by shewing that the public have, from time immemorial, or for at least forty years, or in some cases for twenty years, enjoyed the right of way; for if that is proved, then the law presumes that the right was given by some lost grant. There are also rights of way limited to a particular purpose, which may be proved by immemorial custom, as a way for the inhabitants of a village to or from the parish church. One of the incidents of a highway is, that if it is foundrous, or out of repair, the passenger is entitled to go over the adjacent land, whoever may be the owner of it, so as to avoid the foundrous part of the road. Another incident of the use of a highway is, that the owner may be assessed on it, whether in the nature of a gate, or a wall, or even if a house be built too near so as to encroach on the highway, any passenger has a right to alate the nuisance—i.e., he may himself, without any ceremony, remove the obstruction or demolish the wall, but he must take care not to do more damage than is necessary for the purpose of clearing the road, otherwise he will subject himself to an action. Another incident of the use of a highway is, that the public have an absolute right to use every part of it, and to pass to and fro in all directions. Of course, each must comply with certain well known rules, such as that of giving and taking the road, otherwise, if an accident were to occur, he would be liable for the negligence, if it arose from a neglect of such rules, for these constitute, as it were, the law of the road. It results from this principle, that no person, or body of persons, is entitled to convert part of the highway into a by-road, however useful, other than a highway. Thus in London, and other parts of the country, some vestries and surveyors lately presumed to give leave to a contractor to lay down a tramway in the streets, which was alleged to be a great public improvement. It is, nevertheless, as it practically resulted in giving a monopoly to some persons, and moreover was an

HIGHWAY, in English law, is the place over which a right is enjoyed by the public, of walking,  
riding, or driving. It is often called the Queen's

highway; not because the Queen has any greater or better right than any of the public, but because the imparting of equality with all the subjects enjoy the right of way without distinction. Highways are distinguished into several kinds. 1. A footway, where the public have no right except to walk on foot; 2. A foot and horse way, where the public have the right of walking or riding on horseback; 3. A pack, and drift way—a way used for driving cattle and pack-horses; 4. A foot, horse, and cart way, where the public can walk or ride, or use vehicles of all ordinary dimensions. Navigable rivers are also called highways, but this is rather in a figurative sense. Where the right of way belongs not to the public generally, but to the owner of one or two houses and their tenants, this is called a private way, and is classed among easements.

It has often been disputed, and cannot be said to be yet thoroughly settled, whether a highway must be a thoroughfare—in other words, whether a road which does not lead to any public place can be a highway. The preponderence of authority seems rather to be in favour of the proposition, that it is essential that the highway be a thoroughfare. The modern practice is, in many cases, to include the highway, or some part of it, in the estate. This is generally done by will, or by the dedication, or by grant of the owner, or by the necessity of things or act of parliament. Thus, if a person allow the public for four or five years to pass through his fields without stopping them, the path is, in this case, evidently a highway. It has been shown that it is, in a great many cases, a highway by shewing that the public have, from time immemorial, or for at least forty years, or in some cases for twenty years, enjoyed the right of way; for if that is proved, then the law presumes that the right was given by some lost grant. There are also rights of way limited to a particular purpose, which may be proved by immemorial custom, as a way for the inhabitants of a village to or from the parish church. One of the incidents of a highway is, that if it is foundrous, or out of repair, the passenger is entitled to go over the adjacent land, whoever may be the owner of it, so as to avoid the foundrous part of the road. Another incident of the use of a highway is, that the owner may be assessed on it, whether in the nature of a gate, or a wall, or even if a house be built too near so as to encroach on the highway, any passenger has a right to alate the nuisance—i.e., he may himself, without any ceremony, remove the obstruction or demolish the wall, but he must take care not to do more damage than is necessary for the purpose of clearing the road, otherwise he will subject himself to an action. Another incident of the use of a highway is, that the public have an absolute right to use every part of it, and to pass to and fro in all directions. Of course, each must comply with certain well known rules, such as that of giving and taking the road, otherwise, if an accident were to occur, he would be liable for the negligence, if it arose from a neglect of such rules, for these constitute, as it were, the law of the road. It results from this principle, that no person, or body of persons, is entitled to convert part of the highway into a by-road, however useful, other than a highway. Thus in London, and other parts of the country, some vestries and surveyors lately presumed to give leave to a contractor to lay down a tramway in the streets, which was alleged to be a great public improvement. It is, nevertheless, as it practically resulted in giving a monopoly to some persons, and moreover was an

287
obstruction to others, this was held to be a nuisance, and the parties who took part in it were indicted for the obstruction. And on the same principle, it has been held an indictable nuisance for an electric telegraph company to place their telegraph poles on the strips of land at the side of the road; for though it might be thought for the benefit of the public, instead of the reverse, yet as it practically obstructed the public in the free passage from every part of the highway to every other, it was held to be a nuisance. Nothing but an act of parliament can legalise such uses of a highway, and no person or body now existing has authority to restrict the free use of the Queen's highways, for such a purpose.

The soil of the highway, or rather the right to the ground beneath the highway, is presumed to be (not, as it is said to be in Scotland, in the crown, but) in the adjoining owners. Thus, if the land on both sides of a highway belong to the same owner, then the right to the ground beneath the road belongs to him also; and if the land on one side belongs to a different owner from the land on the other side, then each is presumed to have the right to the ground beneath the highway up to the middle line. This rule is more than a mere theory, for though neither of the adjoining owners can ever interfere with the passage of the public, who have an absolute right for ever to use it if for every lawful purpose, yet the adjoining owner has all the rights incidental to the property which do not interfere with this public right of passage. Thus, if a mine were discovered under the road, the adjoining owner would have the sole right to dig it up, and keep the contents; all that he would require to attend to would be, to leave sufficient support to the surface of the road. So, in like manner, where there are strips of land at the side of the road on which the public are presumed to be solely to the adjoining owner, and the public have no right to their use. Another remarkable consequence follows, that if, for example, a gas company or a water company were to presume to take up the highway in order to lay their pipes under the surface, this is not only an indictable nuisance as regards the public, insomuch as it obstructs the use of the road for the time being, but it subjects the company to an action of trespass at the suit of the adjacent owner, whose property consists of all that lies under the surface of the highway. Another consequence of the same rule is, that if a person is loitering on a highway, not with the intention of using it qua highway, but for the purpose of poaching at night, the courts have held that such may be punished under the right of poaching act, for trespassing on the land of the adjoining owners in search of game.

The repair of a highway, in general, is a burden which falls upon the occupiers of the lands in the parish. Probably the reason is, that they use those highways most, and somebody or other must keep them in repair. Sometimes, however, the burden of repair now falls on the owner of the adjoining land, if it can be proved that he has always, from time immemorial, been in the habit of repairing it, being then presumed there was some good reason for this. The general rule is, however, that the inhabitants of the parish must repair the highways within their bounds, and so incapable of this obligation that no agreement they can enter into will relieve them of such a liability. But though bound to repair, they cannot be called on to widen the road. The common remedy, accordingly, when the road is out of repair, is to indict the parish, when, if guilty, the surveyor will be bound to make a rate, and pay the expenses.

Owing to the defects of the common law, which did not sufficiently give power to widen, shut up, and improve highways, so as to keep pace with the wants of the time, a general act of parliament was passed in 1833, called the General Highway Act, 5 and 6 Will. IV, c. 50, which still regulates the subject. Many minute details are laid down by this act, but substantially the foregoing principles of the common law still govern the subject, the chief alterations being merely in the machinery by which these principles are carried out. The highways are kept in repair in two ways: levying a toll on the highway, and, a person annually appointed by the ratepayers in each parish, and who is vested with the control of the surface of the highway to a limited extent for the purpose of repairing it in due manner.

HIGHWAYMAN—HILL

4 Geo. IV. c. 49, and 1 and 2 Will. IV. c. 43, and 3 and 4 Will. IV. c. 33, were passed for the regulation of highways, which impose various rules, in detail, upon the conduct of the public in the use of turnpike roads. Parish roads are maintained still on the old system of statute labour. Most of the roads are regulated by special acts of parliament, which are to be taken in conjunction with the general acts. When a public-road is obstructed in Scotland, the party is not indictable; but any one of the public may raise an action of declarator, and so establish the right of the public.

HIGHWAYMAN is not a technical legal term, the offence of robbing or assaulting on the highway being included under LARCENY, ROBBERY, or ASSAULT, respectively.

HIGLER. See HAWKERS.

HILARY, St, Bishop of Poitiers, and doctor of the church, although by no means among the most voluminous of the Latin Fathers, yet, from the nature of the subjects on which he was principally connected with the Arian controversy, occupies an important place in the patristic literature of the Western Church. He was born of pagan parents at Lemomum (Poitiers) in the early part of the 4th century. His conversion to Christianity was probably the result of his own study of the prophecies, and did not take place till he was advanced in life. About the year 350 he was elected bishop of his native city, and immediately rose to the first place in the Christian communion of the parts of Gaul in that controversy. Having provoked the displeasure of the court party, he was imprisoned, and sent into exile in Phrygia; but he appears again in the council of Sclencia in 359, and soon afterwards was permitted to resume possession of his see, where he died, 367. The church holds his day on the 13th January. His most important work is that on the Trinity, but his three addresses to the Emperor Constantius, by their vivacity, and by the boldness of their language, have most attracted the notice of critics. His theological writings are especially valuable for the history of the Arian party, and particularly for the doctrinal variations of that sect, and the successive phases through which it passed between the council of Nice and the first council of Constantinople. The best edition of the works of St. H. is that of the Benedictine Dom. Constant (Paris, 1863), or the republication of the 4th additional matter by Maffei (Verona, 1730).—There is a second bishop of the same name who occupies a conspicuous place in the history of the 5th c., HILARY OF ARLES, born in 401, educated at the celebrated monastic school of Lerins, and made bishop of his native city in 429. As metropolitan of Arles, he presided at several synods, and especially at Orange in 441, the proceedings of which involved him in a serious controversy with the pope, Leo the Great. A deposed bishop, named Chlodhion, having carried an appeal to Rome, a council was summoned by Pope Leo, at which H. was present, and in which the condemnation of Chlodhion, as well as that of another bishop, Prolectus, was reversed. H. was again refused to submit to the decision, and soon afterwards quitted Rome—a proceeding which drew upon himself a very severe animadversion. He did not question the authority in itself, but he maintained that it was uncanonically exercised. In the end, however, he sought a reconciliation with Pope Leo, and the dispute was brought to an amicable termination. H. died in his 84th year at Arles in 449.

HILARY TERM, one of the English legal terms dars, from which the courts of law sat at Westminster in banc. The term is appointed by statute to commence on the 11th and to end on 31st January. The name is said to be borrowed from St. Hilary, Bishop of Poitiers.

HILDEBRAND. See GREGORY VII.

HILDESHEIM, an old town of Hanover, capital of the principality of the same name, administratively situated in the river Innerste, in a pleasant valley surrounded by hills, 24 miles south-east of Hanover. It is a very quiet town, with very old houses, the upper stories of which are furnished with balconies. It has been a bishop's seat since 792, and taken in 1157, dating from the beginning of the 11th c., has bronze gates (date, 1015) 16 feet high, and covered with bas-reliefs. There are also in the cathedral beautiful paintings on glass, and many art and other treasures. The church of St. Goelcher, considered a master-piece of architecture, dates from 1133 (restored in 1852), and is surmounted with three pyramidal towers. St. Michael's Church, nearly an unaltered basilica, dates from 1116. It has no manufactures; the inhabitants being employed chiefly in the professions, and in the active trade in corn, yarn, and linen. Agriculture flourishes abundantly in the vicinity. Pop. 16,300.

HILL, SIR ROWLAND, K.C.B., post-office reformer, was born at Kidderminster, December 26, 1793. His father conducted a school near Birmingham, which was celebrated in connection with the 'Hazelwood system of education' (afterwards removed to Bruce Castle, Tottenham), and in which H. was engaged as a teacher when he was 15 years old. He afterwards formed an association which obtained an act for establishing the colony of South Australia, with the design of reducing to practice Mr. Gibson Wakefield's scheme of colonisation. H. became secretary to the Royal Commissioners, who at first managed the affairs of South Australia. He was also a member of the committee of the Society for the Diffusion of Useful Knowledge. The high rate of postage had for many years engaged his attention, and in 1837 he published a pamphlet recommending a low and uniform rate of postage throughout the British Isles. Petitions were poured into the House of Commons in favour of H.'s plan, and in 1837 the House appointed a committee to investigate the merits of penny-postage. In 1840, the principle of a uniform rate of postage was adopted, and an experimental charge of 4d. per letter was levied. This was shortly afterwards followed by the present uniform penny-postage. H. was also in the treasury, and was working out his measure when the Tory government succeeded to power, and dismissed him. A subscription was got up at once to reward a public benefactor, and mark the public sense of his dismissal, and the sum of £15,000 was presented to H. In 1846, when the Whigs returned to office, H. was appointed secretary to the Post-master General. In 1854, he succeeded Colonel Malby as secretary to the Post-office, an appointment which he still (1862) holds. In 1869, he was made K.C.B., avowedly as a recognition of his great public services. The vast and rapid development of the postal system under the penny-postage is mostly described elsewhere (Post-office). The Money-order Office is one of the offshoots of penny-postage, and parliament, in the session of 1861, enacted a system of Post-office Savings-banks upon the post-service, which has been carried out by H. with his usual administrative ability and success. — His eldest brother, MATTHEW DAVENPORT HILL, the recorder of Birmingham, has distinguished himself by his labours for the education of the people, and the reformation of criminals. One of his brothers, Mr. Edwin Hill, the
HILL-HIMALAYA.

HILL, Viscount (Rowland Hill), British general and commander-in-chief, a scion of the ancient and distinguished family of the Hills of Shropshire, was second son of Sir John Hill, Bart., of Hawkstone. He was born on 19th June 1772, entered the army at the age of fifteen, and obtained a captaincy before he was twenty. He took part in the disastrous campaign in which Sir John Moore lost his life. In 1810, under the Duke of Wellington, and displayed conspicuous gallantry, as well as great talents as a commander. In the Peninsular engagements, he was usually intrusted with the most important duties next to those which devolved upon the Duke of Wellington; and when the army returned home, the fame of H. was second only to that of the great commander. He was created Baron Hill of Almarez and Hawkstone, received a parliament seat, and both title and annuity were granted to his nephew in remainder. He was also made G.C.B. He commanded a division at Waterloo, and remained with the army of occupation, as second in command, until it evacuated the French territory. He succeeded the Duke of Wellington in 1825 as commander-in-chief of the army, and dispensed the patronage which he possessed with great impartiality. In 1842, his health declined, and the Duke of Wellington once more took the command of the army. After his resignation, H. was created a viscount. He died unmarried at Hardwicke Grange, county of Salop, December 10, 1842, in his seventy-first year. He was succeeded in his titles and estates by his nephew, Sir R. Hill, Bart.

HILL MUSTARD. See BUNIAS.

HILL STATES, a number of small principalities of India on the left or east side of the Upper Sutlej, comprise about 10,000 square miles, and about 500,000 inhabitants. With the exception of this aggregate name, they have but little in common with each other. Perhaps twenty may be reckoned which have a distinct existence—those best known being Bhagul, Bussahur, and Gurwhal.

HILLAH, or HILLA, a town of Turkey in Asia, in the pashalic of Bagdad, and 60 miles south of the city of that name, is situated on both banks of the Euphrates, and is built on the ruins of ancient Babylon (q. v.). Here the Euphrates is 450 feet in width, and is crossed by a floating bridge. H. is a fortified town, contains a citadel, a mosque, and several well-stocked bazaars. Dyeing, tanning, and manufactures of silk are here carried on. The population, which is fluctuating, may be stated at between 7000 and 10,000.

HILLEG, Hababli (the Babylonian), or Hazaken (the Elder), one of the most eminent and influential doctors of the Jewish law, was born about 112 B.C. in Babylonia, of poor parents, but in the female line of royal (Davidian) descent. Forty years old—so the legend runs—he migrated into Palestine for the sake of studying the law; and of the small sum he earned by hard manual labour, he gave half to the door-keeper of the academy where Shemajah and Abtalian, the great masters of the period, expounded the Halacha (q. v.); and before long, he became one of the favourite and foremost pupils of Abtalian. Five or six years (Sabb. 15 a.) after Herod had mounted the throne, H. was elected Nasi, or president of the sanhedrim. The range of his acquisitions is said to have been immense; embracing not only Scripture and tradition, but nearly all branches of human and 'supernatural' knowledge. Yet he was one of the meekest, most modest, kind, and simple-hearted men. 'Be of the pupils of Aaron, a friend of peace, a promoter of peace, loving mankind, and bringing to the earth the Divine law' (Aboth, ii. 9). 'Do not judge thyself, until the day of thy death' (Aboth, ii. 3). "Do not judge thy neighbour, until thou hast been in his place thyself" (Aboth, iii. 5). Such were some of his most favourite sayings. Still of great character, and highly prudent, if compared with Matt. vii. 12, is the answer he gave to a heathen who, in a spirit of mockery, requested him to teach him "all the law of Moses" while he could stand on one leg. "Do not unto others as thou wouldst not have others do unto thee," H. replied; 'that is all the law; the rest is mere comment' (Babyl. Talm. Shabb. 31 a.). H. was also the first who collected the numberless traditions of the oral law, and arranged them under six heads (Mishnah). The often cited and highly exaggerated dispute between H. and his school and Shammui (q. v.), the contemporary supreme judge of the Sanhedrim (Ab-Beth-Din), and his school, is reduced by itself into a mere theoretical one: the decisions themselves are, with a very few and unimportant exceptions, identical. H., however, was the more popular of the two, and the majority was, on account of the better authorities he was able to quote in his support, generally on his side.

The time of H.'s death is uncertain. He is said to have lived, like Moses, 120 years: 40 years in ignorance of the Law, 40 years as the humblest prophet, and 40 years as the master of the Law. A verse of the dirge composed at his death has survived: 'Woe for the pious, the modest, the disciple of Ezra' (Sanh. 11 a.). For the further influence of his house and school, see GAMILIEL and TALMUD.

HILTED, a term used in Heraldry, to indicate the tincture of the handle of a sword.

HIMALAYA (the abode of snow), from the Sanscrit, hima, snow, and dya, abode, in south central Asia, is the most elevated and stupendous mountain system on the globe. It is not, as sometimes represented, a single chain, but a range of ranges, depending on the gradient of the land with reference to the plateau of Tibet, and separated by deep gorges, the outlets of the streams originating in the melted snow and ice of the interior. The mass of the H. proper extends from the great bend of the Indus in the west, to the junction of the Sampa with the Brahmaputra in the east, or from long. 73° 23' to 93° 40', a distance of nearly 1500 miles, following the curve from south-east to north-west. The mean elevation of the range is from 16,000 to 18,000 feet, but 45 of its peaks are now known to exceed 23,000 feet in height. Of these there are, in Kumaon, Nanda Devi, 25,749 feet; in Nepal, Dhaulagire, 26,826 feet; Mount Everest, 29,028 (the highest known point on the globe); and Kanchanjunga, 25,166 feet; in Bhutan, Chumalari is 23,946 feet above the sea. The southern surface of the H. comprises three distinct regions—first, adjoining the plains of Hindustan, the Tarai, a great belt, extending from the Akhunista, next, the great belt of Saiul Woold, stretching along a great part of the range; and beyond it the Daha, a belt of detritus, extending to the foot of the true mountains. Above these regions, which are extremely unhealthy, are placed the Sanitaries for troops.
Darjeeling, Simla, Murree. There are no plains and but few lakes in the H.; the chief of the latter are Nainital, in Kumaon, 6520 feet, and the lake of Casimir, 5126 feet above the sea.

Snow falls in rare intervals on the mountains as low as 2500 feet, but at 5000 feet it snows regularly every winter. The limit of perennial snow in the H. is 16,200 feet on the south, and 17,400 feet on the north side; an anomaly probably owing to the inhalation of the colder air. The showers of rain and snow that falls there. The high range of the H. forms a vast screen which intercepts and condenses nearly all the moisture carried by the winds from the Indian Ocean, and deposits it on the southern face of the mountains; hence at Churia Punji, 4320 feet above the sea, as much as 600 inches of rain has been known to fall in one year.

Glaciers are found in every part of the range above the snow line, one of these, that of Deotal in Garwhal, is 17,345 feet above the sea. The mean height of the passes in the H. is 17,800 feet, the highest known is Tii Gamin Pass into Garwhal, 29,457 feet, and the highest used for traffic is the Pass of St. Spiuti, 19,560 feet above the sea. All the passes below 19,000 feet are closed with snow from November till May. Trees and cultivated grains attain their highest limits in the mountains at 11,800 and shrubs at 15,200 feet above the sea. The tea-plant can be cultivated along the entire southern face of the H. to an elevation of 8000 feet; but the best is produced at from 2000 to 3500 feet above the sea. Tigers and apes are found at an elevation of 11,000, and the leopard at 13,000 feet, which are the limits of these animals. These same rivers, with their magnificient tributaries, derive their chief supplies from the melting of the snows in the Himalayas, and consequently are in flood at the hottest season of the year when the moisture they supply is most needed.

On account of the majestic height of this mountain-range, and the apparent impossibility of reaching its summit, the imagination of the ancient Hindus invested it with the most mysterious properties, and connected it with the history of some of their deities. In the Puranas, the H. is placed to the south of the fabulous mountain Meru, which stands in the centre of the world (see Meru), and described as the king of the mountains, who was inaugurated as such when Pritha was installed in the government of the earth. As the abode of Siva, he is the goal of penitent pilgrims, who repair to his summit in order to win the favours of this terrific god. His wife was Menah, whose name is applied to demigods Vakrjas engendered by the mere power of their thought.

DINCKLEY, a manufacturing and market town of England, in the county of Leicester, 13 miles south-west of the town of that name, and 99 miles north-west of London. Its parish church, with a beautiful old oak roof, is supposed to have been erected during the reign of Edward III. H. has manufactures of cotton hosiery. Pop. (1861) 6448.

The conduct of H. is also historically interesting in relation to the temporal power of the medieval papacy (see Papacy). Under the successor of Nicholas, Adrian II., a question arose as to the succession to the sovereignty of Lorraine on the death of King Lothaire, the pope favouring the pretensions of the Emperor Lewis in opposition to those of Charles the Bold of France. To the mandate which Adrian addressed to the archbishop of Charles and to the nobles of Lorraine, accompanied by a menace of the censures of the church, H. offered a firm and persistent opposition. He was equally firm in resisting the undue extension of the royal prerogative in ecclesiastical affairs. When the Emperor Lewis III., in opposition to the solemn judgment of the council of Vienne, sought to obtrude an unworthy favourite, Odacer, upon the see of Beauvais, H. boldly renounced, and fearlessly denounced the unjustifiable usurpation. H. died in the year 882. His works were collected in two volis, folio by Pere Sirmont, S. J. (Paris, 1645). Several other pieces of his are found in the 8th vol. of Labbe's Collection de colomies and in the 5th vol. of that of Hardouin; as also in Pere Cellot's Concil. Diumac. (Paris, 1658). Many others of his works, still in MS., are enumerated in Wetser's Kirchen-Lexicon, v. 308.

HIND, the female of the Stag (q.v.) or Red Deer. The term is also sometimes used to designate the female of some other species of deer—never being so applied, however, to any other British or European species; and is sometimes even extended to female antelopes. In the strictest use of the term hind, according to the ancient laws and customs of 'veneric,' it did not become the designation of a female red deer until the third year of its age.

HIND, JOHN RUSSELL, an English astronomer, was born at Nottingham, May 12, 1823. At an early period he became an enthusiast in the study of astronomy, and in 1840 obtained, through the influence of Professor Whewell, a situation in the Royal Observatory at Greenwich; which he remained till June 1844. H. was then sent as one of the commission appointed to determine the exact longitude of Valentia, and on his return was appointed to a
post in Mr Bishop’s Observatory, Regent’s Park, London. Here he made those observations, the results of which have rendered his name renowned in the whole world. He calculated the orbits and declination of more than seventy planets and comets, noted sixteen new movable stars, and three nebulae, and discovered ten new planets, viz., Iris and Flora in 1847, Victoria in 1850, Irene in 1851, Melanome, Fortuna, Callipso, and Thalia in 1852, Euterpe in 1853, and Urania in 1854. In 1851, H. obtained from the Academy of Sciences, Paris, the Lalande Medal, and was elected a corresponding member. In 1852, he obtained the Astronomical Society of London’s gold medal, and a pension of 2000 a year from the British government. He also superintended the publication of the Nautical Almanac. H.’s scientific papers have generally been published in the Transactions of the Astronomical Society, in the Comptes Rendus of Paris, and the Astronomische Nachrichten of Altona. H.’s popular works are—Recent Comets and the Elements of their Orbits (published in the Athenaeum, August 1844); Astronomical Vocabulary (Bano, 1852); The Comets (12mo, 1852); The Solar System (Svo, 1852); Illustrated London Astronomy (Svo, 1853). Elements of Algebra (Lond. 1855), &c. These works, though cheap, are all valuable and entertaining.

HINDU KUSH, or INDIAN CAUCASUS, forms the western continuation of the Himalaya, being sometimes reckoned a part of that colossal range. It extends from the Upper Indus on the E. to the Bamian Pass (q.v.) on the W., stretching in N. lat. between 34° and 36°, and in E. long. between 65° and 75°. Separating Afghanistan on the S. from Turkestan on the N., it sends off the Oxus through the latter, and the Helmund through the former, to two salt lakes—the Oxus to Aral, and the Helmund to Hamûn. The loftiest summit is Hindo Koh, situated about 80 miles to the north of the city of Cabul, and estimated to be more than 20,000 feet above the sea. Unlike the Himalaya Proper, the chain is a water-shed, and is also remarkably destitute of timber; while, like the ridge in question, it presents an appearance of much greater height towards the south than towards the north.

HINDU LAW, RELIGION, &c. See INDIA.

HINDUSTAN, meaning The Land of the Hindus, is a term of the same class as Turkestan, Afghanistan, Parseistan, Belochistan, or Frangistan (the old name of Western Europe). See INDIA.

HINGE, the pivots or joints on which doors, shutters, &c. revolve. The simplest form of hinge is a projection cut upon the substance of which the door is made, and fitted into a hole. This is sometimes done with wooden shutters, and there are examples extant of stone shutters hinged in this manner. The cathedral of Torcello, near Venice, which dates from the 11th c., still has the windows protected with shutters formed of large slabs of stone, hinged on stone pivot. During the middle ages, hinges, as well as very other useful article, were made subjects of ornamentation. The earliest ornamental hinges date from about the 10th century. The first examples are cramped and stiff, and the scrolls are frequently terminated with animal heads. In the early English and decorated styles, the hinges and other metal-work were very elaborate and beautiful in design, and frequently extended over the whole of the doors. In the perpendicular style, hinges were usually very simple in form, the flat paneling of the wood-work not admitting of much ornamental iron-work. In modern times, hinges have almost entirely lost their ornamental character. They are chiefly made of brass and iron, and fitted in the edges of the doors and shutters, where they are concealed. ‘Double-jointed edge-hinges’ are those now most in use. The revival of medieval architecture has, however, given an impulse to the manufacture of ornamental metal-work, and hinges of varied and good design are now generally used in connection with Gothic architecture.

HINNOM, VALLEY OF. See GEBENNA.

HINNY, the hybrid produced between a horse and a female ass. It is smaller than a mule, but the body is more bulky in proportion to the legs, and its strength is inferior. It is less valuable than the mule, although it is more docile. The hinny is rare. It was described by some of the earlier naturalists as a hybrid between the ox and the ass, and even Buffon seems to have entertained the notion.

HINOJOSA DEL-DUQUE, a town of Spain, in the province of Cordova, and 45 miles north-west of the city of that name, consists of spacious streets, with neat white-washed houses, each with a garden or court attached. It has several convents and hospitals, and linen and woollen manufactures. Pop., between 7000 and 8000.

HIOUEN-THSANG, a celebrated Chinese traveller, professing the Buddhist creed, who visited 110 countries and places of India in the first half of the 7th c. (692—645), and gave a very detailed and interesting account of the condition of Buddhism as it prevailed at that period in India. His inquiries having been chiefly devoted to the objects of his veneration, he did not enter so much into details concerning the social and political condition of India as might be desired; but considering the many curious notices he gives on other matters which, besides those of Buddhist interest, came under his observation, and the high degree of trustworthiness which his narrative possesses, his memoirs must be looked upon as one of the most important works on the history of India in general, and of Buddhism in particular, during the period stated. Apparently, he travelled alone, or with a few occasional companions; and wearing the garb of a religious mendicant, with nothing but a staff, wallet, and water-pot, he does not seem to have been exposed to any dangerous adventures on his journey from China to India. It is more remarkable, however, that he incurred no impediment on his way home, when he travelled with 500 packages of books, besides images of Buddha and various sacred relics; and his immunity from danger affords a remarkable proof of the civilised condition of the countries which he described. It does not appear...
HIP—HIP-JOINT.

that the account of his travels was written by himself, for of the two works relating to them neither is the performance of Hioen-Thasang. The first is a bibliographical notice of him, in which his travels form a principal feature; it was composed by two of his pupils, Hoel-li and Yen-Thasong. The latter bears the title of Ta-thang-as-yu-ki, or ‘Memoirs of the Countries of the West, published under the Thang,’ and was edited by Fien-ki, since H. himself, who during 17 years had spoken none but foreign languages, had perhaps lost the facility of writing elegant Chinese. According to a remark added to the title of his work in the imperial Chinese edition, it would follow that it had been translated from Sanscrit into Chinese; but this statement, as Professor Stanislas Julien observes, can only mean that the fundamental part of the work relating to history, legends, &c., was taken from Hindu sources, since it is obvious that the indication of distances and numerous personal observations must have come from H. himself. Both works have been published in a French translation by the distinguished Chinese scholar, M. Stanislas Julien, who has acquitted himself of the great and peculiar difficulties of his task in so creditable a manner, that his Histoire de la Vie de Hioen-Thasang (Paris, 1853), and his Mémoires sur les Contrées Occidentales, par Hioen-Thasang (2 vols, Paris, 1857—1858), have not only become indispensable to the student of Chinese and Sanscrit literature, but will be a lasting honour to M. Julien’s industry and scholarship. An abstract of both works, by the late Professor H. H. Wilson, appeared in the 17th volume of the Journal of the Royal Asiatic Society, pp. 106—137.

HIP, or HIP, the fruit of the rose. It is almost always red, and consists of the enlarged fleshy tube of the calyx filled with hard seed-like actinidia which are surrounded with bristly hairs (setae). The fleshy covering contains mucilage, sugar, gum, malic and citric acids, tannin, resin, and a number of sets. The setae excite itching in the skin. The fleshy part of hips, beaten to a pulp, and preserved with sugar, finds a place in the pharmacopoeia.

HIP-JOINT, is a ball-and-socket joint formed by the reception of the globular head of the thigh-bone (or femur) into the deep pit or cup in the acetabulum, which is known as the acetabulum (so called from its resemblance to the vinegar cups used by the Romans). If the variety of the movements of this joint—viz., flexion, extension, abduction, adduction, and rotation inwards and outwards, and at the same time its great strength are considered, it may well claim to be regarded as the most perfect joint in the whole body.

The reader will form a tolerably clear conception of the relative forms of the acetabulum and the head of the thigh-bone from a glance at the figure, in which the surrounding parts are cut away, and the thigh-bone is drawn out of its socket. The ligaments are usually described as five in number—viz.: 1. The capsular; 2. The ilio-femoral; 3. The teres or round; 4. The cotyloidal; and 5. The transverse. Of these, the capsular ligament, supposed to be removed in the figure, is the most important, and extends from the edge of the cup to the circumference of the neck upon which the ball is carried, enclosing the bony parts in a strong sheath. The ilio-femoral is merely an accessory band of fibres which give increased thickness to the capsular ligament in front, where strength is specially required. The great use of the capsular ligament is to limit the extension of the hip-joint, and thus to give steadiness to the erect posture. The only other ligament requiring notice is the L. teres, or round ligament, which is in reality triangular rather than round, and has its apex attached to the head

the irritating setae. The hips of different species of rose are almost indiscriminately used. In some parts of Europe, hips are preserved in sugar as an article of food, or are dried and used in soups and stews, the ascaridea and setae being removed. For this purpose, the large soft hips of the Apple Rose (Rosa pomifera) are preferred.

HIP-JOINT:

1, 2, 3. pelvic ligaments; 4, 5, the greater and lesser sacro-iliac foramina; 6. the cotyloidal ligament; 7, the round ligament; 8. the cut edge of the lower part of the capsular ligament.

under the name of Conserve of Hips (Conserves Rosea Fruicta, Confectio Rosea Canina, &c.). It is slightly refrigerant and astringent, and is often used as a vehicle or basis for other medicines. Hips eaten entire are a popular remedy for ascariides, on which their action is purely mechanical, and is owing to

(a) Hip opened, showing position of seeds; (b) a seed.
HIP-KNOB—HI PPCampus.

of the thigh-bone, while its base is connected with the cavity of the acetabulum. Its use is not very clearly known, but probably is to limit movement in one direction. It is sometimes absent in cases in which no special weakness of the joint was observed during life, and is of by no means constant occurrence in mammals. The joint is much strengthened by a large number of surrounding muscles, some of which are of considerable power.

In such a joint as this, although the ligaments must at all times assist in preventing dislocation, it is obvious that the articular surfaces cannot, un der ordinary circumstances, be kept in apposition by them, inasmuch as they must be loose in their whole circumference, to permit of the general movements of the joint. The experiments of Weier show that atmospheric pressure is the real power by which the head of the femur is retained in the acetabulum when the muscles are at rest. 'One convincing experiment is easily repeated—that, namely, of holding up a side of the pelvis with its pelvis and lower extremity, the joint not having been opened, and then boring a hole through the acetabulum, so as to admit air into the joint, when the weight of the limb will cause it to drop from half an inch to an inch, the head of the thigh-bone being pulled out of the acetabulum as soon as the air is permitted to pass between the articular surfaces.'—Humphry On the Human Skeleton, p. 74.

HIP-JOINT. Hip-disease differs in so many points of importance from other joint-diseases, and is so serious an affection, that it requires a special notice. Its connection with scrofula is more distinctly marked than that of most other joint-diseases, and it almost always occurs before the age of puberty. It comes on, in children or young persons of a scrofulous constitution, from very slight causes; thus, it is often traced to over-exertion in a long walk, a sprint in jumping, or a fall; and in many cases no apparent cause can be assigned.

In the early stage of the disease, the whole of the structures of the joint are inflamed, and by proper treatment at this period, the morbid action may be sometimes subdued with all its worst consequences than a more or less rigid joint. Usually, however, abscesses form around the joint, and often communicate with its interior; and the acetabulum, and the head and neck of the thigh-bone, become disintegrated, softened, and gritty. In a still more advanced stage, dislocation of the head of the thigh-bone commonly occurs, either from the capsular ligament becoming more or less destroyed, and the head of the bone being drawn out of its cavity by the action of the surrounding muscles, or from a fungous mass sprouting up from the bottom of the cavity, and pushing the head of the bone before it.

It is of extreme importance that the symptoms should be detected in an early stage of the disease; and on the least suspicion of this joint being affected, surgical aid should at once be sought.

As the disease advances, abscesses (as already mentioned) occur around the joint, which sometimes, from the tension they exert on the obturator nerve, occasion extreme pain in the inside of the thigh. True shortening of the limb now takes place, which at the same time becomes adducted and inverted. From this state, if the health is pretty good, and the lungs are sound, the patient may be so fortunate as to recover with an aichylous (or immovable) hip-joint; but the probability is that exhaustion and hectic will come on, and that death will supervene, from the wasting influence of the purulent discharges occasioned by the diseased bone.

The duration of the disease may vary from two or three months to ten or more years.

As the treatment must be left entirely in the hands of the surgeon, it is unnecessary to say more than that the most important points are perfect rest to the affected part, which may be secured by a strong leather splint, or by a starch bandage, the internal administration of cool-hiver oil and tonics, and the application of counter-irritation by means of an issue behind the great trochanter.

HIP-KNOB, an ornament carved in stone or wood, set on the apex of a gable or hipped roof, and forming a kind of Finial (q. v.).

HIPPARCHUS, the first systematic astronomer on record, was born, according to Strabo, at Nicaea, in Bithynia, about the beginning of the 2d c. B.C. Of his personal history, nothing is known. According to Fabricius, H. wrote nine separate works, of which only the last and least important, A Commentary on Aratus, has come down to us. Of the other works treated of astronomy and geography, the only authority we have regarding the discoveries made by H. is the Synthetis of Ptolemy, and from it we learn that H. discovered the 'procession of the equinoxes,' determined the place of the equinox among the stars, established the solar and lunar theories, invented the Astrolabe (q. v.), and drew up a catalogue of upwards of 1000 stars, determining the longitude and latitude of each. As Ptolemy was also an astronomer, there is some difficulty in allotting to each his share of praise for the discoveries mentioned in the Synthetis, which difficulty has given rise to much discussion, resulting inupport of the claims of Hipparchus. See Delambre's Histoire de L'Astronomie Ancienne (Paris, 1817).

HIPPOROSCIDE. See FOREST FLY and SPIDER FLY.

HI PPCampus, a genus of Osseous Fishes of the order Lophocharacina (q. v.), and of the family Synaptidae (see Pipe-Fish), by some naturalists made the type of a separate family, Hippocampus, remarkably distinguished by the prehensile tail, which is tapering, and quite destitute of fin. The species, which are not very numerous, but some of which are found in the seas of all parts of the world, are fishes of very extraordinary form and habits. They have the jaws united and tubular, as in the pipe-fishes; the body compressed, short, and deep; the whole length of the body and tail divided by vertical and transverse ridges, with tubercles at their intersections. The scales are ganoid, clothing the whole body in a kind of armour. The males have pouches on the tail, in
which the eggs are carried till they are hatched. From their appearance, these fishes have received the name of Sea-horses. They swim in a vertical position, and are always ready to cutwine their tails around sea-weeds, or even with one another. They are very interesting objects in an aquarium. One species, H. brevirostris, is occasionally found on the shores of Britain, and in some parts of H. gavialis, in the Grecian mythology was a sea-horse—half fish, half horse—which served Poseidon (Neptune).

**HIPPOCRAS,** an aromatic medicated wine, formerly much used in this country, and still employed on some parts of the continent. The following was the method of preparing it: Twelve parts of Lisbon were mixed with an equal quantity of Canary wine. Brusied spices of various kinds were digested in the wine for three or four days, after which it was strained, and two pinnas and a half of lump-sugar were added. It was doubtless an admirable cordial.

**HIPPOCRATES,** the most celebrated physician of antiquity, was the son of Heracleus, who was also a physician, and belonged to the family of the Aesopidae, the subject of the present notice being either the 19th or the 17th in descent from Aesop. His line of descent was traced in Latin by a writer named Albinus, who was said to have been descended from Hercules. He was born in the island of Cos, probably about the year 460 B.C. He is said to have been instructed in medicine by his father and by Herophilus, and in philosophy by Gorgias of Locrinum, the celebrated sophist, and Democritus of Abdera, whose views, when affected by madness, he afterwards adopted. After spending some time in travelling through different parts of Greece, he settled and practised his profession at Cos, and finally died at Larissa, in Thessaly. His age at the time of his death is uncertain, and is stated by different ancient authors to have been 85, 90, 104, and 109 years.

**Class II.**—Works perhaps written by Hippocrates. These are eleven in number, and one of them is the well-known *Oath of Hippocrates,* or *Hippocratic Oath.* The others consist of works written before Hippocrates, whose author is conjectured. These are by quite unknown authors; and willful forgeries. For anything like a full account of his views, we must refer to the various writers who have treated of the history of medicine. We can here only mention that he divides the causes of disease into two principal classes: the first consisting of the influence of seasons, climates, water, situation, &c.; and the second of more personal causes, such as the food and exercise of the individual patient. His belief in the influence which different climates exert on the human constitution is very strongly expressed. He attributes this influence both to the conformation of the body and the disposition of the mind, and hence accounts for the difference between the hardy Greek and the Asiatic. The four fluids or humours of the body (blood, phlegm, yellow bile, and black bile) were hence called *seats of disease; health was the result of the due combination (or crisis) of these,* and illness was the consequence of a disturbance of this crisis. When a disease was proceeding favourably, these humours were in a state of change, which were hence called *critical.* His treatment of diseases was cautious, and what we now term expectant; it consisted chiefly and often solely in attention to diet and regimen; and he was sometimes reproached with letting his patients die by doing nothing to keep them alive.

The works of Hippocrates were translated at an early period into Arabic. They were first printed in a Latin translation in 1529 at Rome. The first Greek edition (the Ahline) appeared the following year at Venice; an edition by Mercourialis appeared in 1588, one by Focinius in 1595, and one by Van der Linden (still much esteemed) in 1665. Other editions have appeared under the editorship of Chartier, Kuhn, &c., the latest, and incomparably the best edition, is that of Litteri, in 10 volumes, the first of which appeared in 1839, and the last in 1861. An edition by Erasmus, with a Latin translation, is now in course of publication at Utrecht, at the expense of the University of Amsterdam. The Latin title runs as follows: *Hippocritis et aliorum Medecorum veterum Reliquiae. Editidus Franciscus Zacharias Ermerinus,* 4to. The first volume appeared in 1859, and another in 1862. An excellent English translation of The Genuine Works of Hippocrates was published in 1849, in 2 vols., by the late Dr Adams, under the auspices of the Sydenham Society.

**HIPPOCRENE** (derived from 'hippos, a horse, and kretē, a fountain) is a fountain on Mount Helicon, about 20 stadia above the grove of the Muses, and, according to the mythical account, was produced by a stroke from the hoof of the horse Pegasus (q.v.). It was sacred to the Muses. In modern times, some have attempted to identify it with a fine spring at Makriastas, and this opinion is most probably correct. See Helicon.

**HIPPODAMIA,** the beautiful daughter of Cene- manos, king of Pisæ, in Elis, and the Pleiad Asterope. It had been predicted to her father that he should be slain by his future son-in-law; he therefore stipulated that every suitor of his daughter should run a chariot-race with him; this was to be the consequence of defeat. Thirteen, or, as some say, seventeen suitors had already been conquered and slain, when Pelops came to Lydia. Pelops
bribed Myrtillus, the king's charioteer, and thus succeeded in reaching the goal before Gnooas, who had kept himself. He then was killed by the wife of Pelops, and the mother of Atreus and Thyestes. She afterwards destroyed herself from grief, at being reproached with having led her sons to murder each other.

HIPPODROME (Gr. hippos, a horse, and dromos, a race-course), the Greek name for the place set apart for horse and chariot races. Its dimensions were, according to the common opinion, half a mile in length, and one-eighth of a mile in breadth. In construction and all important points of arrangement, it was the counterpart of the Roman Circus (q. v.), with the exception of the arrangement of the chariots at the starting-place.

In the hippodrome, the chariots were arranged so as to form two sides of an isosceles triangle, with the apex towards the goal and a little to the right side. But as this would have given the chariots on the left side a longer course than those on the right, the hippodrome was constructed with the right side longer than the other (see figure of Circus). The start was effected by setting free the chariots on the extreme right and left, and when they came opposite the next two, by setting them free also, and so on. The motion in the hippodrome was also much wider than the Roman circus, to allow room for the greater number of chariots, for though we have no precise information as to the number that usually started in one race, we know that Alcibiades on one occasion sent seven; Sophocles mentions ten chariots as competing at the Pythian games; and the number at the Olympic games must have been considerably greater. There is a beautiful description of a chariot-race in Homer (Iiad, xxii. 282—500). The golden age of the hippodrome was during the Lower Greek Empire. The Blue and Green factions in the hippodrome carried their animosity into all departments of the public service, and laid the foundation of that perpetual disunion which rendered the Byzantine empire a prey to every aggressor.—The term Hippodrome has been given to a circus constructed in 1845 at Paris, and also to a large field in the plain of Longchamp, near Boulogne, used as a race-course.

HIPPOGRIFF, or HIPPOGRYPH (Gr. hippoc, a horse, and grifh, a griffin), a fabulous animal, which has been represented as a winged horse, with the head of a griffin. The hippogriff figures largely in the Orlando Furioso of Ariosto.

HIPPOLYTUS, the name of several saints and martyrs of the early church, among whom the chief interest is concentrated upon one who is believed to have flourished in the early part of the 3d c., to have been Bishop of Portus, near Rome, and to have suffered martyrdom under Alexander Severus. All the facts connected with the history of this saint have long been the subject of much doubt and controversy; and the interest of the discussion has been much heightened of late years by the discovery of a very curious and important work, certainly of the age of the supposed H., and calculated, if a genuine work of that author, to throw a most curious light upon the early history of the church. The work in question was one of several Greek MSS. obtained at Mount Athos in 1842, by M. Menas, an agent of the French government, and was published in 1851, at the expense of the university of Oxford, to which it was recommended as a work of exceeding interest for the history of the early church. Raymond of Tournai, who undertook the task of editing it, M. Miller published it as a work of Origen, under the title of Origens Philosophumena. The late Baron Bunsen was the first to conjecture that the true author was H., but he was mistaken as to the particular work of H., which he took it to be; and after a time the question of the authorship remained in much uncertainty. Some critics still adhered to the opinion that the author was Origen; some ascribed the work to another priest Caesarius; and others, again, to Tertullian; and others, in fine, to some unknown Novatian heretic. The result of the discussion, however, seems to be, that although Bunsen was mistaken in supposing this treatise to be a work of H., which Philius has described as a "little treatise against heretics, by that author, yet it is in reality a larger treatise on the same subject and by the same author.

There still remained, however, a further question, namely, Who is the H. who is to be regarded as the author? Without reconning many later saints of that name, Dr Dohlinger, in his Hippolytus und Hippolytus, enumerates at least six contemporaneous, or nearly contemporaneous, with the supposed H. of Portus. It must suffice to state, that although not absolutely certain, the opinion that the author of the Philosophumena was the H. already known in the ancient church as a writer and as a martyr, has gained the almost universal acceptance of his age.

From the autobiographical details contained in the treatise, added to the particulars already known, we learn that this H., the time and place of whose birth are uncertain, was, about the year 218, Bishop of Portus, near Ostia, a suburban see of Rome, and as such, a member of the ecclesiastical council of that city. This fact receives a very decisive confirmation from a statute discovered in Rome, in 1861, which is connected with the name of this H., and with the title of his work, "Portuensis," and the paschal cycle of which H. is known to have been the author. In the persecution of Maximin, 233, H. was exiled to the island of Sardinia, from which he was permitted soon afterwards to return; but in a new outbreak of the persecution, he was put to death, probably in 238. Probably, from the connection of his see with the Roman Church, H. took an active part in the affairs of that church, and placed himself in violent opposition to the Bishop Callistus, whom he denounces in the treatise in the most unmeasured terms, both as to his private character and his public administration, as a person of most discrepant antecedents; as well as his formalism in the management of the church, and especially in the administration of penance, after his election to the see. The tone which he adopts towards the Roman bishop, indeed, is so disrespectful as to appear to the Protestant critics a clear and conclusive evidence that, in the church of the 3d c., that bishop cannot have possessed the supremacy which the advocates of the papal pretensions assert to him. It is difficult, in truth, to conceive any bishop in the modern Roman system addressing the pope in such terms as those which H. applies to Callistus.

The Roman Catholic critics reply, that the very violence of the language employed, and the acrimonious nature of the imputations contain their own refutation; and they contend that no argument can be founded on H.'s opposition to the authority of the Roman bishop, inasmuch as not only the opinions expressed in this very treatise, but also the direct testimony of Prudentius (Hymn xii. v. 170—180), shew him to have been tainted with the Novatian heresy, or rather, although somewhat earlier, with the same opinions which in Novatus are termed heretical, and which eventually took root in the Novatian schism. The validity of this plan, however, is strongly controverted by J. Husen. The works of H., which are numerous, and which
comprise dogmatistical, exegetical, ascetic, and chronological treatises, were first published in a collected form by Fabricius, at Hamburg, 1716—1718. They are also found in the second volume of Gallandius.—See Bunsen's Hippopotamus and His Age (1852; 2d ed. 1854); Miller's Origines Philologiconina (Oxford, 1851); Döllinger's Hippopotamus und Kallistus (Halle, 1853); Wordsworth's St Hippopotamus and the Church of Rome in the Third Century (Lond. 1853).

Hippomane. See Manchinel.

Hippophææ. See Sallow-Thorn.

Hippophagi ('eaters of horse-flesh,' from Gr. hippos, a horse, and phagein, to eat;), according to the accounts of the old geographers, were a Scythian people, living north-east of the Caspian Sea, where roam, at the present day, the Kalimucks hordes, who, retaining all the peculiarities of the old Scythians, still regard horse-flesh as a dainty.

In Europe, repeated attempts have been made in modern times to introduce the practice, which has even been depended on economical grounds, but as yet they have failed to create a public taste for horse-flesh.

Hippopotamus (Gr. river-horse;), a genus of pachydermatous quadrupeds, constituting a family by itself, and of which, until very recently, only one species was known as now existing, although the fossil remains of others indicate the greater abundance and of the distribution of the form in other periods of the earth's history. The largest and best known species, H. amphibius, is—or, within historic periods, has been—found in almost all parts of Africa, to which quarter of the globe it is entirely confined. A smaller species, H. luteus, has recently been described as an inhabitant of the rivers of Western Africa within the tropics, and is said to differ remarkably from the common species, and from all the fossil species in having only two incisors instead of four, in the lower jaw. The common H. is one of the largest of existing quadrupeds, the bulk of its body being little inferior to that of the elephant; although its legs are so short that it is almost touches the ground, and its height is not much above five feet. It is extremely aquatic in its habits, living mostly in lakes or rivers, often in tidal estuaries, where the saltness of the water compels it to resort to springs for the purpose of drinking, and sometimes even in the sea, although it never proceeds to any considerable distance from the shore. Its skin is very thick—on the back and sides, more than two inches; it is dark brown, destitute of hair, and exudes in great abundance from its numerous pores a thickish oily fluid, by which it is kept constantly lubricated. The tail is short. The feet have each four toes, nearly equal in size, and hoofed. The neck is short and thick. The head is very large, with small ears, and small eyes placed high, so that they are easily raised above water, without much of the animal being exposed to view. The muzzle is very large, rounded, and tumid, with large nostrils and great lips concealing the large front teeth. The H. cuts grass or corn as if it were done with a scythe, or bites with its strong teeth a stem of considerable thickness neatly through. The skull, while it is distinguished by remarkable peculiarities, corresponds in the most important characters with that of the hog. The respiration of the H. is slow, and thus it is enabled to spend much of its time under water, only coming to the surface at intervals to breathe. It swims and dives with grace and ease, and often walks along the bottom, completely under water. Its food consists chiefly of the plants which grow in shallow waters, and about the margins of lakes and rivers; and it probably renders no unimportant service in preventing slow streams from being choked up by the luxuriance of tropical vegetation, the effect of which would, of course, be an increase of the extent of swampy land. It often, however, leaves the water, chiefly by night, to feed on the banks, and makes invades on cultivated fields, devouring and trampling the crops. It is a gregarious animal; and the havoc wrought by a herd of twenty or thirty is very great, so that wherever cultivation extants, war is waged against the H., and it disappears from regions where it formerly abounded. Thus it is no longer found in Lower Egypt, although still abundant further up the Nile. It is taken in pits, which are digged in its usual tracks; it is killed by poisoned spears, is pursued by means of canoes, is harpooned, and is shot with the rifle. The flesh is highly esteemed; the fat, of which there is a thick layer immediately under the skin, is a favourite African delicacy, and when salted, is known at the Cape of Good Hope as Zee-koe speek—that is, Lake-cow bacon. The tongue, and the jelly made from the feet, are also much prized. The hide is used for a variety of purposes; and the great canine teeth are particularly valuable as ivory, and are a very considerable article of African commerce.

The H. is lively and playful in its native waters; it soon learns to avoid man, and when it cannot retire among reeds for concealment, it dives and remains long under water, raising only its nose to the surface when another breath becomes necessary. The female H. may sometimes be seen swimming with her young one on her back. The H. is generally inoffensive, but is occasionally roused to fits of rage, in which it becomes extremely dangerous, particularly to those who pursue it in boats. The voice of the H. is loud and harsh, and is likened by Burckhardt to the creaking and groaning of a large wooden door. That the H. is capable of being tamed, and of becoming much attached to man, has been sufficiently proved by the instances of living specimens in London and Paris. The first H. brought to Europe in modern times, a young one from the Nile, arrived in London in 1830. The H., however, sometimes appeared in the spectacles of the ancient Romans. It is very generally supposed to be the Behemoth of the book of Job.

Fossil species.—Some six species of H. have been described from the later Tertiary strata—the Pliocene and Pleistocene of Lycell. They occur in fresh-water marls, and in the bone-caves, into which they had been carried for food by the carnivorous animals that used the caves as dens. One species found in England and in considerable abundance

Hippopotamus (H. amphibius).
HIPPURIC ACID—HISPANIA.

In the southern countries of Europe, was of a size as much greater than the living species, as its companions, the mammoth, was greater than the living elephant.

HIPPURIC ACID (C₁₂H₁₄NO₄.H₂O) is a compound of great interest both to the chemist and to the physiologist. It derives its name from having been first discovered in the urine of the horse, and the human. The fact that it occurs in the traces in the urine of the horse, has a faintly bitter taste, and is soluble in boiling water and in spirit, but are only sparingly soluble in cold water and in ether. Its chemical bearings show that hippuric acid is intimately associated with benzoic acid on the one hand, and with glycine (or glycocoll) on the other. The acid is a product of the metamorphosis of the bodily tissues, especially of herbivorous animals. It is a normal constituent of the urine of the horse, of the human, and of some of the animals of the animal kingdom. It is, therefore, probably to be found in the urine of all vegetable feeders. In the human urine of healthy persons living on an ordinary mixed diet, it occurs in very small quantity, but it is increased by an exclusively vegetable diet, and in the well-known disease diabetes.

Although hippuric acid usually occurs in mere traces in human urine, we can artificially produce it at will in the body, and cause it to be eliminated in comparatively large quantity by the kidney. If we swallow benzoic acid, it seems to take up glycine or the elements of glycine in its passage through the system, and thus to form hippuric acid, which appears abundantly in the urine. The hippuric acid occurs on the animal or organic side of the equation in combination with bases, and chiefly as hippurate of soda and hippurite of lime. The last-named salt can be obtained by the mere evaporation of the urine of the horse.

HIPPURITIES, a very remarkable genus of fossil bivalve shells, peculiar to the Cretaceous strata, and so abundant in some of the Lower Chalk beds of the Pyrenees and other places, that the series has received, from some continental geologists, the name of the Pyreneis. The external form of the shell is so anomalous, that the genus has been tossed about by naturalists in an extraordinary manner; some have called it a coral, others an ameboidea, others a balanus, but the majority hold it to be a mollusc, differing, however, among themselves whether it is a brachiopod, a conchifer, or a cephalopod. The true relation of the genus has been lately determined by Mr. S. P. Woodward, who has published a full description of its curious and anomalous structure, in the Journal of the Geological Society, vol. xi. p. 40. He has shown that it is a lamellibranchiate mollusc. The lower and fixed valve is produced and tapering, in some species reaching a length of more than a foot. On the one side are the foot-furrows, representing the siphonal, muscular, and ligamental inflections of the shell. The upper and free valve formed a flat covering to the larger lower valve. Sixteen species have been described.

HIRING is a contract by which one employs, for a limited time, another's property or labour for some consideration or reward. Where the thing hired is land or houses, see LANDLORD AND TENANT. In the Roman law, hiring was divided into—1. Locatio rei, or the hiring of a thing; 2. Locatio personarum, or the hiring of work and labour; 3. Locatio custodise, or the hiring of care and services to be performed or bestowed on the thing delivered; 4. Locatio operis mercium vehendarum, the hiring of the carriage of goods from one place to another. These phrases are sometimes employed both in the law of England and Scotland, but the subjects are more conveniently treated under other heads: see LINS, LODGINGS, SERVANTS, CARRIERS, SHIPPING. The only branch of the subject to fall properly under this head, is the hiring of task-work or job-work. Sometimes it is difficult to establish a contract of this kind, but in general there must be either an express or implied contract to pay for the services. Thus, if A, paying for horse running away, at some expense catches it, and brings it back to B, there having been no contract or engagement on B's part to pay, he is not bound to pay A for his services, however beneficial they have been; nor can A keep B's horse till such expenses are paid. So, if B has deposited a chattel with A, who has incurred extraordinary expense in preserving it, B is not bound to pay anything. In the Roman law, however, and in the law of Scotland, he is nevertheless entitled to be paid for his services, for the contract is not rescinded on these grounds, unless there was an express stipulation to that effect. During the progress of the contract, it is sometimes material to know which of the parties bears the loss in case of failure. It is difficult to lay down the rule in such cases, for everything depends on the nature of the contract. Whoever is the owner, in law, of the material at the time, bears the loss of it by an accidental fire. If, however, he has hired a horse or a cart to run away, to make or engage to make or engage to make, he must furnish the materials for a fixed sum, this is, in fact, two contracts—in one, a sale of the materials, and also work and labour bestowed on them; and in case of destruction of the subject before completion, the loss of the materials falls on the hirer, and the loss of the labour falls on the workman. So if a printer engaged for a fixed sum per sheet to print and complete a book, the hirer would bear the accidental loss of the paper, and the printer the loss of his labour and skill. Much, however, depends in all these cases on the terms of the contract. Where a workman engages to do work, he implicitly warrants to have reasonable skill, otherwise, if the work is useless, he cannot recover his money, and the hirer who hires. In the case of robbery while goods are in the hands of a workman to work up, if the robbery resulted from his negligence, he bears the loss. So if he merely lost it. If in case of a horse or chattel being hired, and accidental damage done, the onus in England lies on the owner to prove negligence in the hirer; but in Scotland the contrary rule prevails, and it lies on the hirer to prove he used due care.

HITSCHBERG, an important manufacturing town of Prussia, in the province of Silesia, is romantically situated at the foot of a mountain, and at the confluence of two streams, the Boler and the Zacken, 30 miles south-west of Liegnitz. The town is ancient, and is still gilt about by a double line of walls. Its Protestant church, a Gothic edifice, is worthy of mention for its beauty. In the case of robbery while goods are in the hands of a workman to work up, if the robbery resulted from his negligence, he bears the loss. So if he merely lost it. If in case of a horse or chattel being hired, and accidental damage done, the onus in England lies on the owner to prove negligence in the hirer; but in Scotland the contrary rule prevails, and it lies on the hirer to prove he used due care.

HISPANIA, the name by which Spain was known to the Romans. According to W. von Humboldt, the name of work and labour of the original name, which he derives from Espaha, a Spanish word, meaning a 'border' or 'limit,' and which he
understands to imply that the country formed the margin of Europe towards the Western Ocean. Of the other ancient names of the country, the chief are Iberia—the common designation among the Greeks, and believed to denote specially the region of the Iberian peninsula, modern Ebro and Hesperia, on account of its western situation.

Little definite or accurate knowledge of H. was possessed before the time of the Romans. The coming of the Carthaginians and the alarm of the Romans, and led to the struggle on Spanish soil of these two great rivals. The triumph of the Romans, as every reader knows, was ultimately complete, and for the next two or three centuries, these undefeatable conquerors set themselves to the thorough subjugation of the whole country. This was finally effected in the time of Augustus, who also founded many Roman cities, adorned with splendid architecture, such as Caesar Augusta (Zaragoza), Emerita Augusta (Merida), Pax Julia (Beja), Pax Augusta (badajoz), Legio VII. Gemina (León), &c. In addition, that emperor completed the system of military roads across the peninsula, and most of the great features of Roman conquest everywhere—began as early as 124 B.C. and thus threw open Spain from end to end; so that great numbers of Romans floucked into the country, and settling there, mixed with and moulded the native races, whose name of whom completely absorbed Roman habits, and were spoken of as Topati.

To what stock of the human family the old Iberi of H. belonged, is one of the questions vexata of scientific ethnography. That they are represented in modern times by the Basques (q.v.) is, however, universally admitted. Niebuhr holds that H. was originally divided among two peoples, the Celts and the Iberi, from a mixture of whom arose the Celtiberi (q.v.). The more common opinion, however, both in ancient and modern times, is that the Celts were not exclusively aboriginal with the Iberi, but invaders from Gaul; and that they, rather than the Iberi, were victorious in the strife that ensued.

HISPANIOLA (Little Spain). See Domingo, San, and Haiti.

HISTOLOGY (derived from the Greek words histos, a web or texture, and logos, a science) is the science which classifies and describes the structural and morphological elements which exist in the solids and fluids of organised bodies. It is identical or nearly so with general minute anatomy and with microscopic anatomy. Although it may be traced to the times of Malpighi (1628—1694), who discovered the blood corpuscles, and of Leuenhock (1632—1723), who, with comparatively imperfect optical means, added much to our knowledge of the minute structure of the tissues, it never made any definite progress till the second decennium of the present century, when the compound microscope began to assume its present improved form. It was by means of this microscopico-chemical examination that the structure of the different horny tissues was first clearly exhibited, and it was thus proved that nails, cow's horn, and whalebone are similarly composed of aggregations of individual cells. Again, in the investigation of the nervous tissue, and of many other structures, chemistry and the microscope have been most usefully combined. During the last quarter of a century, no department of medical science has made such rapid progress as pathological.

In Germany, it has been successfully cultivated by Schwann, Hensel, Valentin, Remak, Kolliker, Virchow, Leydig, Frey, and others, scarcely less distinguished; in Holland, it has been actively prosecuted by Darwin and others; Lebert, Mandl, Robin, and others, have contributed to the French literature of the subject; while amongst our own countrymen, the names of Todd and Bowman, of Goodar, Queckett, J. H. Bennett, Lockhart Clarke, and Beale, deserve honourable notice.

HIT (the is of Herodotus), a town of Turkey in Asia, is situated on the right bank of the Euphrates, in the pachalie of Bagdad, and 110 miles west-north-west of the city of that name. It is estimated to contain about 1500 houses, and is remarkable for the fountains of bitumen in the neighbourhood. These fountains or pits are as abundantly productive at the present day as they were in the earliest ages. From them bitumen and naphtha are obtained in great quantity, and exported.

HITCH, a knot or noose by which one rope is fastened to another, or to some other object, as a hook, a cleat, a ring, &c. There are many sorts of latches—as clove-hitch, midshipman's hitch, rolling-hitch, &c. Several of these knots will be described and figured under KNOT.

HITCHCOCK, Edward, D.D., LL.D., an eminent American geologist, born at Deerfield, Massachusetts, U.S.A., May 24, 1793, was head of the academy in his native place 1815—1818, pastor of the Congregational church at Conway 1821—1825, professor of chemistry and natural history in Amherst College 1825—1845, principal and professor of natural theology and geology 1845—1854, and still fills his favourite professorship of geology. In 1824, he published The Geology of the Connecticut Valley, a work which was well received, and opened the way to H.'s advancement. In 1845, he was appointed a state geologist, and as such, made a thorough survey of the geology and mineralogical resources, including also the botany and zoology, of Massachusetts, in 1830; of part of New York in 1836, and of Vermont in 1837. He published the fruits of his researches regarding Massachusetts in 1831; and after issuing supplementary reports in 1833 and 1838, embodied the whole in his Final Report on the Geology of Massachusetts (2 vols. 1841), which is the standard work on this subject. In 1859, H. was appointed agricultural commissioner for his native state, and received instructions to visit and examine the chief agricultural schools of Europe, which he did; and subsequently published his Report on the Agricultural Schools of Europe, a valuable work. But he has chiefly distinguished himself in the geological department of natural theology. His work on the connection between geology and religion is Religion of Geology and its connected Sciences (1851)—has had a very wide circulation on both sides of the Atlantic. H. has come forward prominently as an exponent of the fossil footprints in the Connecticut Valley. The most important of these mentioned above, are Elementary geology, with an Introductory Notice by Dr Pep Smith (1840), a work which has become extremely popular, having gone through 25 editions in America, and eight in England; Fossil Footmarks in the United States (1848); Ichnology of New England (1858).

HITPADESA (literally, 'good advice,' or 'salutary instruction,' from the Sanscrit hita, good, salutary; and upadesa, advice, instruction) is the name of the celebrated Sanscrit collection of tales and the contents of which have passed into almost all the civilised literatures of the earth. The collection itself, in the form in which we possess it, is founded on older works of a kindred nature, and is classed by the Hindus among their ethical works. See Sanscrit Literature.
HITTEREN—HOBES

HITTEREN, a considerable island on the west coast of Norway, lies about 47 miles west of the town of Trondheim, and is about 30 miles long by 10 miles broad. Pop. about 3700, most of whom live by fishing.

HITZIG, FERDINAND, a German biblical scholar, was born 23d June 1807, at Hauingen, Baden, and educated at Heidelberg, Halle—where the influence of 'Eisennius determined him in favour of Old Testament studies—and at Göttingen. In 1833, he was called to Zürich as professor of theology, with a special view to the exegesis of the Old Testament; but his lectures, though mainly devoted to that department, have embraced also the New Testament, and the languages of the East, especially the Semitic. The first work which established his fame was his 'Uebersetzung u. Ausdeung d. Proph. Jesaías' (1833). Besides a translation of the Psalms, with a commentary (1835—1836), he has furnished for the 'Exegetisches Handbuch zum A. T.' the commentaries on the twelve minor prophets (1838; 2d ed. 1851), on Jeremiah (1841), Ezekiel (1847), Ecclesiastes (1857), Daniel (1850), and the Song of Solomon (1855), with a translation of all the prophetic books as a supplement (1854). He is also known by 'Die Erklärung d. Alphabets' (1840), 'Die Grabgeschichte d. Darius zu Jemodem-Rasamon' (1849), 'Uebers. u. Mythologie d. Philister' (1846), and by considerable contributions to periodicals.

HIVA-OA, the principal island of the Marquesas group in the South Pacific Ocean, is about 22 miles long by 10 miles broad. Its northern point is said to have lain in lat. 9° 24' S., and in long. 139° 4' W. Pop. stated at 6500.

HIVITES ('Milllanders' according to Ewald or 'Villagers' according to Gesenius), a Canaanites people, who in the time of Jacob are found occupying the uplands of Ephraim, and later, the slopes of Hermon and the region westward towards Tyre.

H'LA'SSA, the capital of Tibet, satiated on the Dzangtsu, in lat. 30° 45' N., and long. 91° 27' E.; the largest town in Central Asia, about 9500 feet above the level of the sea. It is famous for the contents in and near it, composing the ecclesiastical establishments of the Dalai-lama, whose personal residence is in a convent on the adjacent Mount Botala. H. is to Buddhism what Rome is to Catholicism, it is the head-quarters of the hierarchy of the Buddhists of the Dalai-lama, exercise of the priestly control over nearly all Mongolia, as well as Tibet. The city lies in a fertile plain, extending about 12 miles from north to south, and about 125 miles in length. Mountains and hills encircle it. A Chinese garrison is quartered near the Mount Botala, whose temples are resplendent with gold and precious stones. Since the expulsion of the Nepalese in 1792, no foreigners are allowed entrance from the south. Pop. conjectured at 24,000.

HOADLEY, BENJAMIN, D.D., an eminent English prelate, was the son of the Rev. Samuel Hoadley, master of the Norwich Grammar School, and was born at Westerham, in Kent, November 14, 1676. In 1691, he entered Catherine Hall, university of Cambridge, where he became tutor after taking his degree of M.A. In 1701, he was chosen lecturer of St Mildred in the Poultry, London, and from this time began to attract attention as a controversial writer. His 'Reformation of the Church of England,' appeared in 1703, which, like all his other performances, though agreeable to the sentiments of the educated laity of the Church of England, was exactly the reverse to the great body of the clergy, both established and dissenting. Next year, he obtained the rectory of St Peter's, Poor, London, and was soon after engaged in a controversy with Dr Atterbury (q. v.) on the extent of the obedience due to the civil power by ecclesiastics. While this work was conducted by H. in such a way as to secure for him the applause of the House of Commons, who, in their address to the queen (Anne), referred to the important services he had rendered to the cause of civil and religious liberty. In 1719, H. was transferred to the rectory of Norton St. Peter, in Surrey; and in 1715, when the accession of George L. had secured the triumph of Whig principles, was made Bishop of Bangor; but it is affirmed that he never visited this see, for fear of exciting a 'party fury.' His principality was William Law. Hallam speaks of having read forty or fifty pamphlets on the question. In 1721, H. was transferred to the see of Hereford; in 1723, to that of Salisbury; and in 1734, to that of Winchester. In 1735, he published a 'Plain Account of the Nature and End of the Lord's Supper,' and in 1754—1755, two volumes of sermons, which were highly esteemed. He died April 17, 1761, in the 80th year of his age.

HOARSENESS. See THROAT, DISEASES OF.

HO'BART TOWN, the capital of Van Diemen's Land, or Tasmania, stands on the Derwent, near its entrance into Storm Bay, on the south coast of the island. It is in lat. 42° 53' S., and long. 147° 21' E. The mean temperature for the year is 52° 1/2 in winter, and 63° 1/2 in summer. According to the latest returns, the population is about 29,000. Besides the official buildings, which it possesses as the seat of government, H. T. has a college and several churches. The principal trade is in wool, the natural harbour is bordered by a noble quay, along which ships of the largest size can lie.

HOBBES, THOMAS, was born at Malmesbury, on the 5th April 1658, and was the son of a clergyman of that town. At the age of 14, he went to Oxford, and was put through the usual course of Aristotelian logic and physics. His instructions in the philosophy he afterwards held in very small estimation. At the age of twenty, having taken his degree and quitted Oxford, he was recommended to Lord Hardwicke, afterwards Earl of Devonshire, as tutor to his eldest son, this being the commencement of an intimate connection with that great family which lasted through his long life. In 1680, he was sent abroad with his pupil, and made the tour of France and Italy. After his return, he still continued to live with the Devonshire family, and his residence in London afforded him opportunities of becoming acquainted with Bacon, Raleigh, Ben Jonson, and the other distinguished men of the time. Meantime, he was occupied with his classical, political, and philosophical studies, and prepared for publication his first work, a translation of Theocritus, which came out in 1628, he having now attained the mature age of forty.
Hobby—Hochheim.

The Earl of Devonshire having died in 1626, and the young earl, Hobby's pupil, in 1628, he was plunged in great grief, and took the opportunity afforded him of going abroad with the son of Sir Gerrase Clifton, and remained some time in France. In 1631, however, his connection with the Devonshire family was resumed. By the desire of the dowager-countess, he undertook the education of the young earl, the son of the former pupil, then only thirteen. In 1634, he went to Paris, and on this occasion was much in the society of Father Mersenne. He returned to England in 1637. He seems then to have applied himself to the composition of his first original work, entitled Elementa Philosophicae de Cire, which was printed in Paris in 1642. This is the first exposition that he gave of his moral and political philosophy. His advocacy of pure and unrestrained monarchy as the best possible form of government, with an absolute submission on the part of the subjects both in law and in morality and religion to the will of the monarch, has probably given more general offence than any political theory ever propounded. It has been made the subject not merely of incessant attack, but of gross misrepresentation. He published soon after two small treatises, entitled Human Nature, and De Corpoare Politico. The first contains his views as to the constitution of the mind, and entitles him to be considered as the father of modern systematic psychology. Although the work is valuable in itself, he still considers it as a prelude to the other treatise, De Corpoare Politico, or on the nature of society, which is here handled for the second time by him, and in much the same strain. He goes over the whole ground a third time in the Levanthan, published in 1651, the fullest and perhaps the best known exposition of his views on mind, religion, and society, which is more in the nature of a systematic study of any particular subject.

He stood in favour of pure monarchy, which he represents as having grown out of a primitive contract between the sovereign and the people, moved by the desire to escape from all the evils of a state of nature, which is a state of war. He is far from justifying tyranny; on the contrary, he enjoins upon the monarch a government according to just laws, and considers that this is more likely to be obtained by the government of a single person, whose selfish aims must be soon checked if the supreme power were distributed in a number of hands.

After the meeting of the Long Parliament in 1644, he had returned to Paris, and was at the civil troubles. In 1647, he was appointed mathematical tutor to the Prince of Wales, afterwards Charles II., and stood high in the esteem of that prince; but the obnoxious character of his writings, especially after the publication of the Leviathan, so offended the royalist clergy, in common with all other sects, that Charles was induced to part with him; and he himself, being constitutionally timid, took the alarm for his personal safety, and abruptly fled from Paris to England. In England, he found himself safe, the Protestant government according him the most ample toleration. Very different was his position after the 'glorious' restoration of his own friends: for although Charles granted him a pension of £400 a year, the dislike to his views was so general that they were condemned by parliament in 1666, and he was even in danger of still severer measures. His connection with the Earl of Devonshire, with whom he lived in the latter part of his life, was no doubt a powerful protection to him. His old age was fruitful in additions to his writings, and was marked by some sharp controversies. His last works were a translation of Homer, and a History of the Civil Wars. He died on the 4th September 1679, in his 92d year.

Hobby (Falco subbuteo), a small species of falcon, a native of all or most parts of Europe, and of many parts of Asia and Africa. It is in its utmost length, about 12 or 14 inches. It is grayish-black or bluish-gray on the upper parts, each feather edged with yellowish-white, and the whole form is very elegant. The H. is occasionally seen in Britain, but is rare—rarer now than it seems to have been in former times. It was often employed in falconry, and trained to fly at pigeons and even at partridges.

HOBOKEN, a city in New Jersey, United States, on the west bank of the Hudson River, opposite New York, with which it is connected by several steam-ferries. It has beautiful pleasure-grounds, called the Elsian Fields, and heights which afford a fine view of the cities of New York and Brooklyn, harbour, and fortifications. It is a great summer resort, and is rapidly becoming an important city. Pop. about 10,000.

HOCHE, Lazare, one of the most eminent generals of the French republic, was born 25th June 1768, at Montreuil, a faubourg of Versailles. In 1785, he entered the army, rapidly obtained promotion, and was raised, in 1793, to the command of the army of the Moselle. Here he was opposed to the Duke of Brunswick, the commander of the Prussian army, and was by him repeatedly defeated. He was more successful against the Austrians, whom he drove out of Alsace. His next important service was putting an end to the civil war in La Vendée, which he accomplished in a prudent and patriotic manner. After having been sent, in the winter of 1796, as commander of the troops in the unfortunate expedition to Ireland, he was on his return appointed to the command of the army of the Sambre and Meuse. On the 15th April 1797, he crossed the Rhine at Neuwied, and had defeated the Austrians in several battles, when his career was stopped by the armistice concluded between the Archduke Charles and Bonaparte at Leoben. On the 15th Fructidor, he was suddenly taken ill in the camp at Wetzlar, and died 18th September 1797.

Hochheim, a small town in the duchy of Nassau, situated on an elevation sloping down to the right bank of the Main, about three miles from Mainz on the road to Frankfurt. The sunny slopes which here skirt the Main produce excellent wine of several varieties, which go by the general name of Hochheimer; from this comes the English name of the city.
Hoc, now given indiscriminately to all wines from the Rhine regions.

HOCHKIRCH, or HOCHKIRCHEN, a village in the district of Bautzen, in Saxony, half-way between Bautzen and Lobau, was the scene of a battle during the Austrian War of Succession (1744-1748) during the Seven Years' War. Frederick II. of Prussia, with an army of 30,000 strong, having taken up an almost untenable position at H., was attacked at five a.m., under cover of a thick fog, by Marshal Daun, with 50,000 Austrians, and compelled to retire to the heights of Dres. Here he was again attacked by the Duke of Arenberg, and after a conflict of five hours' duration, again retired. He lost 9000 men killed and wounded, and 101 cannon. He himself, and almost all his generals, were wounded. The Austrians lost 8000 men. On 20th and 21st May 1813, a series of battles took place here between the French and allies. See Bautzen.

HOCHSTADT. See BLESHEIM.

HODGKINSON, Eaton, professor of the mechanics of engineering in University College, London, and the chief authority on the application of iron to architecture and engineering, was born at Alton, near Northwich, Cheshire, 20th February 1789. At the age of 21, he settled in Manchester, and there commenced the study of mechanics. At this time the principal authority on iron beams was Tredgold (q. v.), but his theories were overtaken by those of Playfair, who satisfactorily established a theory of his own on this subject. H. next made a series of 227 experiments on the strength of pillars, and here again his opinions came into conflict with those of Tredgold, Mosley, &c., and with the same triumphant result. Almost all the researches were carried on in conjunction with, and at the expense of, Mr Fairbairn (q. v.). For his important experiments and calculations, and general co-operation in the construction of the Britannia Bridge, he received a first-class medal at Paris in 1855. His investigations are in general scattered through the Transactions of the British Association for the Advancement of Science (see especially vols. iv. and v.), and in the Memoirs of the Manchester Society (the most important of which are in the volumes for 1822, second series, and 1831). He also edited Tredgold on the Strength of Cast Iron, adding a supplementary volume containing his own theories of 1842. H. died in June 1861, at Broughton, near Manchester. See Strength of Materials, and Tubular Bridges.

HODOMETER is an instrument for measuring the distance travelled over by any conveyance, and consists of an arrangement of toothed wheels, like clock-work, fixed on one side of a machine, and connected with the axle, from which motion is communicated to it. An index and dial show the exact distance the vehicle has travelled.

HOE, an implement of gardening and of agriculture used for stirring the soil, drawing up earth to plants, thinning plants in drills, clearing the ground of weeds, &c. There are many forms of this implement, all of which may be referred to two classes—draw-hoes and thrust-hoes, the former having the blade almost at right angles to the handle; the latter almost in the same plane with it. The thrust-hoe, or Dutch Hoe, is chiefly used for killing weeds, and for stirring ground to a very slight depth, while the draw-hoe, although used as an implement of gardening, is scarcely used in Britain as an agricultural implement, except for the thinning (singling) of turnips, in which it is always employed. But in some countries it is very extensively used in place of the spade. In some parts of the West Indies almost all the tillage of the ground is done by the hoe. It is more adapted than the spade to the use of labourers whose feet are not provided with shoes. Hoes intended for clearing land, or for the plough and spade, are much larger and heavier than those used in British gardening, and are raised much higher, and brought down to the ground with greater force, somewhat like the pickaxe. Hoes for stirring verdant soils are sometimes made with prongs instead of a blade.

In the improved agriculture of the present day, implements called Horse-hoes are extensively used. They are intended for purposes corresponding with those of the thrust-hoe, and may be generally described as consisting of thrust-hoe blades, variously modified, and attached to a frame in order to be drawn by a horse. Various contrivances are employed to accommodate the blades to inequalities of surface, &c. Horse-hoes can only be employed for crops sown in drills; and the drills must be perfectly parallel, if more than one interval is to be cleared and stirred at once. With the sowing machines now in use, however, this is secured. In turnip-husbandry, a horse-hoe with several blades is often used to clear away the weeds from one interval.

HOE'S MACHINE. See PRINTING.

HOEVEN, Jan Van Der, an eminent living Dutch Naturalist. He was born in 1801 at Rotterdam, and after studying medicine at Leyden, established himself as a physician in his native town, where he remained till 1835, when he was elected to the professorship of zoology in the university of Leyden, a situation which he still holds. His most important work is his Handboek der Dierkunde (Leyden, 1827—1833, in 2 vols.), of which a second edition, entirely recast, appeared in 1846; a German translation was published in 1848; and an English translation, by Professor Clark of Cambridge, under the title Handbook of Zoology, was issued, with important additions, both by the author and the editor, in 1856—1858. The fact that most of his works are memoirs, and written in Dutch, is a great check to their general perusal by English and French naturalists. Jan must not be confounded with his brother, Cornelis Pruys van der Hoeven, who is professor of botany in the university of Leyden, and is the author of several important works, amongst which may be especially mentioned De Historia Medicinalis (Leyden, 1842), and De Historia Morborum (Leyden, 1846).

HOF, a manufacturing town of the kingdom of Bavaria, in Upper Franconia, is situated in a fruitful district on the Saale, 32 miles north-east of Bayreuth. Besides extensive manufactures of leather, and linen and woven fabrics, an important transit trade, arising from its position on the frontier of Bavaria, and on the railway connecting that country with Saxony, is here carried on. Iron and coal mines are worked in the vicinity. Pop. 8550.

HOFFER, Andreas, the patriotic leader of the Tyrolese, was born at St Leonard, in the valley of Passeier, 22nd November 1756. In 1781, he led a body of Tyrolese against the French on the lake of Garla; in 1808, secret deputies, amongst whom was H., arrived at Vienna, to represent the Archduke Charles, and to ask aid from the French, and their wish to be reunited to Austria. By the desire of the archduke, Baron von H Dormay sketched for them a plan of an insurrection, which met with such success that, in three days, from the 11th to the 13th of April 1809, nearly the whole country
was liberated. Napoleon, however, was victorious in Austria, and at once marched three armies to the Tyrol, to subdue the rebellious peasantry, who had been abandoned by the Austrians, in accordance with the armistice of Znaim (July 12, 1809). At first, H. conceived himself in a cave in the valley of Passyere; but when Spechbacher, Josephin Haspinger, a Capuchin, and Peter Mayer, at the head of the armed population, renewed the defence of the Tyrol, he repeatedly defeated the enemy. He then lost his retreat, and took the leadership of the Tyrolese. At the battle fought on the 12th of August on the Iselberg, Lefèvre was driven from the Tyrol. H. continued to conduct the civil and military administration of the Tyrol, and in 1817 was appointed assistant professor of chemistry at the University of Bonn. When the Royal College of Chemistry was established in London in 1845, H. was recommended by Liebig as highly qualified for the important post of superintendent to the new institution. This college, which has since merged into the Laboratory of the Royal School of Mines, is still under his direction, and owes much of its high character to his teaching and his scientific reputation.

On the elevation of Professor Graham from the post of chemist to the Mint to the office of master of that institution, H. was appointed his successor. His chemical knowledge has been applied to several important practical points, amongst which may be especially noticed his examination of the armistice of Regensburg, London, conducted by order of government. In conjunction with Dr. Bem Jones, he has edited the later editions of Tawnon's Manual of Chemistry. His numerous contributions to the Annales de la Chimie et de l'Industrie, to the Transactions of the Chemical Society, and to the Philosophical Transactions of the Royal Society, are for the most part on the very highest departments of organic chemistry; and in 1854 a royal medal was awarded to him for his two memoirs on the Molecular Constitution of the Organic Bases, contained in the Philosophical Transactions and the Transactions of the Chemical Society. H. is now president of the Chemical Society. It was in the course of these researches that he discovered in coal-naphtha aniline, the basis of the new colours mauve and magenta, which had previously been only obtained from indigo. His latest publication (1862) is a lecture delivered before the Royal Institution on these two popular dyes.

Hoffmann's Anodyne LIQUOR is the old name for the Compound Spirit of Sulphur Ether of the London pharmacopoeia, and is a mixture of ether, alcohol, and ethereal oil. It is often prescribed with laudanum, in order to prevent the nausea which often accompanies its use.

HOFNWY, a village of Switzerland, in the canton of Bern, and situated six miles north of the town of that name. It has been long famous as the seat of the educational and agricultural institution founded here by the late M. Fellenberg (q.v.). The institution is now carried on under the management of Dr. E. Fellenberg.

HOG (Sus), a genus of pachydermatous quadrupeds, of the family Suidae (q.v.). The neck is carried straight forward from the trunk, and is very thick and strong. The skin is very thick, and mostly covered with stiff bristles, among which a short curled hair is often also found. The scales of the back of the neck generally become a mane in wild hogs, and particularly in the males, although, in domestication, this tends to disappear. The muzzle is elongated, and terminated by a movable large and very cartilaginous nose, furnished at its extremity with a special small nose, and used, along with the tusks, as an implement for turning up the soil in search of roots and other food. There are 6 incisors, 2 canine teeth, and 14 molars in each jaw, the lower incisors
HOG—HOG PLUM.

projecting forwards; the canine teeth long and strong, projecting and curved, becoming formidable tusks in wild boars, and large and powerful even in the females in a wild state. The feet have each four toes, the lateral ones small, and scarcely touching the ground, all separately hoofed. The tail is short. The stomach shows mere traces of division. The food is chiefly vegetable, but perhaps no animals may more properly be called omnivorous; and although, even in a wild state, hogs are not to be reckoned among beasts of prey, they not unfrequently, even in domestication, kill and eat small animals that come in their way, as many a housewife may have occasion to observe in respect to chickens.—The Common Hog (S. scrofa) appears to be a native of most parts of Europe and Asia, and domesticated swine were found by the first navigators in many of the islands of the southern seas. The wild boar is still found in the forests of many parts of Europe, and was at one time an inhabitant of those of Britain, where it was protected by game-laws in the 19th and 18th centuries; but what time it ceased to exist as a wild animal in Britain is uncertain. The adult males, in a wild state, are generally solitary; the females and young gregarious; and when assailed by wolves or other beasts of prey, will defend themselves vigorously, the strongest animals placing themselves in the front, and the weaker seeking shelter in the rear. The chase of the wild boar is one of the most exciting sports of Europe or of India, particularly when carried on without the rifle, and on horseback with the spear ('pig-sticking'). The speed of the animal is very considerable, and the chase sometimes extends to six or seven miles. Although the use of its flesh was prohibited to the Jews, and the prohibition had been confirmed by the Moslem law, the hog has been a domesticated animal from a very early period, and its flesh constitutes a large part of the food of many nations. The fecundity of the hog is great; with proper treatment, it will produce two litters generally, of 4–8 pigs each, although sometimes there are as many as 14 in a litter. Vast quantities of the flesh are consumed in various forms in the British Islands and North America, as pork, fresh or salted, bacon, ham, &c. Brawn (q. v.) is an esteemed English luxury. The fat of the hog, which is produced in a thick layer under the skin, is an article of commerce, and of various use under the name of LARD (q. v.). The skin of the hog is made into leather, which is particularly esteemed for saddles. The bristles, particularly of the wild boar, are much used for brushmaker.

There are numerous varieties of the domestic hog, of which some have erect, and some pendent ears; and those are most esteemed which exhibit the greatest departure from the wild type, in shorter and less powerful limbs, less muscular and more rounded forms, &c. The Chinese breed and the Neapolitan have been of great value in the crossing and improving of the breeds commonly reared in Britain, giving rise to the improved white and black breeds respectively. Hogs are profitably kept wherever there is much vegetable refuse on which to feed them, as by cottagers having gardens, farmers, millers, brewers, &c. They are often allowed to roam over fallow ground, which they graze up for roots, and over stubble-fields, which they glean very thoroughly. They are also fed in woods—an ancient practice—where they consume acorns, beechmast, and the like. When they are fed, as is sometimes the case, chiefly on animal garbage, their flesh is less palatable and less wholesome. The hog, a reputation which it does not deserve, of peculiar filthiness of habits. It is true that it wallows in the mire, as the other pachyderma also do, to cool itself and to provide itself with some protection against insects, and it searches for food in any puddle; but its sleeping-place is, if possible, kept scrupulously clean. The too common filthiness of pigs is rather the fault of their owners than of their occupants; and a clean and dry sleeping-place is of great importance to the profitable keeping of hogs.

The hog is not inferior to other quadrupeds generally in intelligence. It can be easily rendered very tame and familiar. Its acuteness of scent has been turned to account in making it search for truffles; and an instance is on record of a pig having been used as a pointer, in which service it learned to acquit itself extremely well. Instances have occurred of the use of the hog as a beast of draught.

The forests of the island of Papua or New Guinea produce a species or variety of hog (S. Puscura), more widely different from the common hog than its breeds are from one another. It is 18 or 20 inches high, with short ears, and very short tail. The colour is mostly brown. The Papuans have not properly domesticated this animal, although they often trap the young ones and keep them till ready to be killed for food. The flesh is very delicate; the hog has a reputation which it does not deserve, of peculiar filthiness of habits. It is true

of a resinous juice, and in the drupe having a nut with 2–5 cells and seeds, instead of one cell and one seed. The species of Spandias are trees and shrubs with pinnate leaves, which have a terminal leaflet, and flowers in racemes or panicles. Some of them produce very pleasant fruits, among which may be reckoned S. pumpea and S. latena; the species generally called Hog Plum in the West Indies, because they are a common food of the Indians, both in their raw and dried state, S. pumpea has fruit about an inch in length, ovate or

Hog Plum.
HOG RAT—HOG'S HEAD.

oblong, purple or variegated with yellow; the pulp yellow, with a peculiar but agreeable acid and aromatic taste. The fruit of *S. taberqua*, called *jabuticaba* in the north of Brazil, is about twice the size of a large gooseberry, oblong, yellowish, with a leathery skin and sweetish acid pulp. A much esteemed Brazilian dish is prepared of milk, curds, sugar, and the pulp of this fruit, from which also a refreshing beverage is made for use in fevers. The tree is remarkable for the numerous round black tubers—about eight inches in diameter—which it produces on its widely spreading roots, and which are very cellular, and full of water. These roots are evidently intended for the wants of the trees in the dry season, and are often dug out by travellers for the sake of the water, of which each tuber yields about a pint. —Closest allied to *Spondias* is the genus *Pouteria*, to which belongs the Vi or *Tahiti Apple*, formerly *Spondias dulcis*, a very fine fruit of the South Sea Islands.

HOG RAT, or *HUTIA* (Capromys), a genus of quadrupeds, of the family Muridae, differing from rats in having four grinders on each side in each jaw, with flat crowns. The tail is round and slightly hairy, and is used for support in sitting erect, as by some of the species. They are of great use for aid in climbing trees, and these animals are very expert. They make much use of their fore-paws, as of hands. Their food is entirely vegetable. They are natives of Cuba, where they are found in large numbers in the woods. They were much used as food by the aborigines. The best known species is of the size of a small rabbit.

HOGARTH, William, a celebrated painter and engraver, born in London in the year 1697, served his apprenticeship to a silversmith in Cranbourne Street, named Ellis Gamble, and next studied for some time under Sir James Thornhill, the historical painter, being, however, defeated in the attempt he made for the chairs of which are the prints illustrative of *Hudibras* (Lond. 1796). He now tried his hand at portrait-painting, and soon had ample employment, though he never cared anything for this branch of art. In 1730, he married (clandestinely) Maria Thornhill, and soon after began to display his extraordinary talent for representing in pictures the follies and vices of his time. In 1733, appeared his 'Harlot's Progress,' a series of six pictures, which, like his other work, was executed by himself. It was these engravings, and not the original paintings, that made H. a rich man, and enabled him to keep his carriage at the age of forty-eight. The 'Harlot's Progress' was followed by other moral histories and satirical representations of vice and folly, such as 'The Rake's Progress,' published in eight engravings, 'Southwark Fair,' 'A Modern Midnight Conversation,' 'The Distressed Poet,' and 'Strolling Actresses in a Barn.' The success of these works was great, and inspired H. with the belief that he could also win a reputation as an historical painter. After several ineffectual attempts, he recovered from his delusion, and returned to the path which nature had appointed him. In 1740 he published 'The Times,' in 1745, 'Marriage à la Mode,' in a series of six engravings, the pictures for which were purchased for the National Gallery; and in 1748, 'The March to Finchley.' In 1753, he published his *Anatomy of Beauty*, a work which excited much opposition and ridicule, and H. is generally held to be erroneous in the conclusions at which he arrives. In 1755 appeared 'Four Prints of an Election,' and in 1762, 'The Times,' a cutting satire upon Pitt. He died in 1764, and was buried at Chiswick, where a handsome monument was erected to his memory, with an inscription by his friend Garrick. A part of his art, H. was long thought not to have excelled, but modern opinion is more favourable in this respect. There has never, however, been any but one opinion regarding the greatness of his thought and invention, and his deep insight into the characteristics of his time and country. The moral of his satire is always stern, true, and unmistakable. A handsome edition of his works from the original plates, retouched by H. Malt, was published by Nicholas (3 vols. Lond. 1821—1822); others appeared at Leipzig (1831—1835; 3d. edit. 1841), and at Stuttgart (1839—1840).

HOGG, James, a Scottich poet, was born in the district known as the Forest of Ettrick, in Selkirkshire, in 1772, and was at school for two or three winters before he reached the age of eight. At that early age, he entered upon the occupation of shepherd. His first song appeared anonymously in 1801, and having gone shortly after to sell his employer's sheep in Edinburgh, he sold off 1000 copies of verses which he had written. In the same summer, Scott visited the Ettrick Forest in search of materials for his Border Minstrelsy, when H. made his acquaintance, and placed in his possession a number of ballads, taken down from the recitation of persons resident in the district, which appeared in the third volume of the *Minstrelsy*, in 1803. In the same year, he published *The Mountain Bard*, the proceeds of which, together with two prizes for essays he received from the Highland Society, amounted to £300. With this sum he took a farm, which proved a disastrous speculation. In 1810, he began a course of regular authorship. In 1813, his poem *The Queen's Waltz* appeared. In 1814, he married; and although he afterwards went to live on a farm given to him by the Duke of Buccleuch, he busied himself more with books and booksellers than with sheep and grazing. His pen was profitable, which was more than the could bring his farm to be. He died at Altrive, on the 21st November 1835. His works are numerous, comprising, in addition to those already mentioned, *Modern of the Moor*, *The Pilgrims of the Sun*, *The Jacobite Emigrants*, *Border Garland*; and some songs of great beauty. He also wrote extensively in prose. His prose works are,—the *Bromide of Eildon*, *Winter Evening Tales*, *The Three Perils of Man*, *The Three Perils of Women*, *A Friend in Need*, *Legends*, and *A Life of Sir Walter Scott*.

After Burns, H. is unquestionably the greatest peasant-poet which Scotland has produced. His finest work, both in conception and finish, is *The Queen's Waltz*. The general flow of the poem is lively and harmonious, while in one portion, that of 'Kilmeny,' the reader seems to hear 'the horns of Elfland faintly blowing;' and in another, 'the Witch of Fife,' he is introduced into the weirdest witch and wizard world. His prose works are very unequal, but they occasionally display great humour, and always abound in graphic description.

HOGMANAY, or HAGMEN, a word of doubtful derivation, applied in the north of England and Lowlands of Scotland to New Year's Eve. In the *New York* it is customary for persons to go on, 'Hogmanay night,' from door to door, asking in rude rhymes for cakes and cheese (and sometimes for money), on receiving which they pass on to the next house.

HOG'S HEAD, an old English measure of capacity. For wine, it was equivalent to 63 gallons; for ale 35

233
and been, to 54 gallons. In the United States, it is still used as a measure for liquids, equivalent to 63 gallons; but when used for tobacco, it varies in different states from about 750 to 1200 lbs.

HOGUE—CAPE HOGUE.

Hohenlinden, a village in Upper Saxony, with 250 inhabitants, famous for the victory gained there by Moreau over the Archduke John, 3d December 1800. After the expiration of the armistice concluded at Paesdorf, on the 13th November, Moreau took up a position on the plateau between the Isar and the Inn, and the Austrian army, under the Archduke John, on the right bank of the Inn. The Austrian main body advanced amidst drifted snow, and attacked the division of Gruyer and Frederick von Stauffen, the French general; but the French receiving considerable reinforcements under Ney, the assailants were driven back; and being attacked in the rear, were totally routed. The victory was likewise decided at other points in favor of the French, who were only prevented from pursuing the vanquished by the inclemency of the weather, the badness of the roads, and the short winter day. The Austrians had 8000 men killed and about 11,000 made prisoners, including 150 officers and 100 pieces of artillery. The French had 5000 men killed and wounded. In consequence of this battle, the negotiations between the belligerent powers were resumed, and shortly after ended in the Peace of Lunéville.

Hohenstaufen, a German princely house, which kept possession of the imperial throne from 1138 to 1234. The founder of the family was Frederick von Buren, who lived about the middle of the 11th c., and assumed the name of H. from a castle of that name, the ruins of which are still to be seen on the summit of the Hohenstaufen Berg (2240 feet), a hill on the left bank of the Danube, about 30 miles below Stuttgart. A son of his was the Chevalier Starhemberg, Lord of H., who steadfastly supported the Emperor Henry IV., and in return received the duchy of Swabia. Duke Frederick, at his death in 1165, left two sons—Frederick II., the One-eyed, and Conrad; the latter was immediately compacted in Swabia by Henry V.; and in 1112 the latter received the duchy of Franconia. After the death of Henry V., his family estates fell to the House of H.; and Louchaire of Saxony was elected as his successor in the empire.

On his death, so as to secure the peace of Saxony, he revoked the grants made by previous emperors to the House of H., and thus gave rise to a furious war, in which Duke Frederick (his brother Conrad being absent in the Holy Land) had to encounter, single-handed, the whole power of the emperor, the House of Zähringen, and Henry the Proud, Duke of Bavaria and Saxony. After Conrad’s return, fortune at first seemed to favor the brothers, but in 1135 they were compelled to implore the emperor’s forgiveness. They were then put in possession of all their estates. Conrad, in 1138, was elected Emperor of Germany, under the title of Conrad III. The succeeding emperors of this family were: Frederick I. (q. v. 1190–1197), Philip II. (1190–1197), Philip III. (1198–1298), Frederick II. (q. v. 1212–1251), and Conrad IV. (1251–1254).

Hoehenstein, a small manufacturing town in the kingdom of Saxony, situated 12 miles north-east of Zwickau. Woollen, cotton, and linen goods, and machinery, are the principal items of manufacture. Pop. 5380.

Hohenzollern, a province of Prussia, consisting of a narrow strip of land entirely surrounded by the territories of Wurtemberg and Baden. Superficial area about 480 square miles; pop. (1858) 64,235. The territory, whose surface is generally mountainous, is divided into the districts of Sigmaringen and Hechingen, which mark as subdivided principalities. The seat of provincial government is at Sigmaringen. H. is watered by the Neckar and some of its affluents, and by the Danube, which crosses it; it is also traversed by the eastern offshore from the mountain range. The Rhine and the Oest are united. The mountain valleys are productive, and yield an abundance of fruit and corn, and flax in sufficient quantities for exportation; the forests abound in fine timber; there are iron mines in some of the mountain districts, which also yield gypsum, salt, and coal. The principal branches of industry are agriculture and the rearing of cattle, and the manufacture of toys and other articles in wood.

The population belongs almost exclusively to the Roman Catholic religion, and is under the jurisdiction of the Archbishop of Freiburg. There is a Catholic college at Hechingen.

The Hohenzollern family traces its descent from Count Cisaro, who lived about the beginning of the 9th c., and founded a castle near Hechingen, on the Zollern heights, whence his descendants derived their patronymic. About 1165 the first separation took place, Frederic IV., founding the elder branch, and Frederic I., the younger branch, on the Franconian line. The elder line was subdivided, in 1576, into the branches of H. Hechingen and H. Sigmaringen. Frederic VI., the representative of the younger line, a 1743 received from the Emperor the investiture of the electorate of Brandenburg, thus founding the present reigning dynasty of Prussia. The two branches of the elder line continued unbroken till 1849, when, in accordance with a family compact formed in some of which the elder branch, H. Hechingen and H. Sigmaringen ceded their respective rights and principalities to that monarch, who agreed to pay an annuity of 15,000 thalers to the former, and one of 25,000 thalers to the latter. The princes were to retain their estates and bear the title of Highness, but were to exercise no act of sovereignty.

Hokkanga, a river of New Zealand, enters the Southern Ocean on the west coast of the North Island lying in lat. 35° 39’ S., and long. 173° 26’ E. This point is almost the antipodes of Taungier, on the south side of the Strait of Gibraltar.

HOLBACH, PAUL HENRICH DISTRICT, BAXEN

von, a French philosopher of the 18th c., was born of wealthy parents, at Heidelberg, in 1729. At an early age, he went to Paris, where he continued to reside during the remainder of his life. He died 21st June 1789. As H. was remarkable for his agreeable social qualities, and kept a good table, the most eminent thinkers and writers of the day, such as Condorcet, Diderot, Duclos, Helvetius, Raynal, Rousseau, Buffon, &c., were in the habit of assembling at his house. The witty Abbé Galiani called H. le maître d’hôtel of philosophy. Here speculation is said, was written to a length, that Buffon, D’Alembert, and Rousseau were compelled to withdraw from the circle. H. was the zealous champion of naturalism, and contended not only against Christianity, but against moral positive religion. His principal work is the Système de la Nature (published in 1770). In this work, the author endeavours to explain the natural principles of morality, and to investigate the origin of the conflicting opinions on the subject. He discusses the maxims of religious morality, and takes a rapid survey of
social and savage life. He touches on the so-called 'social compact,' and in the course of his observations tries to prove, among other things, that self-interest is the ruling motive of man, and that God is only an idea derived from the very nature of man. The materialism of the French philosophes of the 18th c. is nowhere more pernicious and paltry than in the writings of Holbach. It is but fair to state that his life was better than his books. He was a man of good heart, and in spite of his theory, of most unseemly benevolence. When the Jesuits fell into disgrace during the reign of Louis XV., H., though he hated their system, and had written against them in the days of their prosperity, made his house an asylum for his old foes when the clouds gathered round them.

HOLBEIN, HANS, the Younger, one of the first masters of German art, was born at Grunstadt in 1497. He learned the rudiments of art from his father, Hans Holbein the Elder, also a painter, of great merit (born 1469, died 1526). When little more than 16 years of age, he visited several houses and churches at Basel with portrait, frescos, and altar-pieces. Tradition has preserved many of his droll sayings, and his life is more rich in anecdote than those of most Italian painters. H. growing tired of Basel, Erasmus, who took a great interest in him, and endeavoured to induce him to abandon his irregular course of life, introduced him to Sir Thomas More, who kept him engaged in England for nearly three years, and then invited Henry VIII. to view the pictures. Henry, surprised and delighted, exclaimed: 'Is the artist still alive, and is he to be had for money? More presented H. to the king, who took him into his service, and rewarded him liberally. H. continued to reside in England, highly esteemed and fully employed, till, in 1554, he died of the plague. Though chiefly, and at many periods of his life almost exclusively, a portrait-painter, in this style he stands on a level with the great Italian masters, and takes precedence of all his German contemporaries. His portraits are not ideals, but nature apprehended in its most natural form, created by kinship and intuition, and executed with perfect truth. To the earlier part of his career belong his most celebrated paintings, including 'The Last Supper,' 'The Dance of Death,' several pictures in the Dresden Gallery, two famous portraits of sixtual and amusing character, and one of his greatest and most perfect. His style of colouring is entirely free from the mannerism of those Flemish painters who had studied in Italy. Some splendid and able portraits by H., belonging to this period, are to be seen in the Louvre at Paris, in the Berlin Museum, at Longford and Windsor Castles. Eighty-seven sketches of persons belonging to the court of Henry VIII. by H. are still extant. His 'Dance of Death,' the illustrations of the Old Testament, and three sets of alphabet prints, would certainly entitle him to rank as one of the first wood-engravers, supposing them to have been more clearly designed, but likewise engraved by him. This opinion has, however, been disputed, and the question remains undecided at the present day. A selection from H.'s pictures in the library at Basel were published in lithographs in 1829, by Birmann and Sons at Basel.—Compare Hans Holbein der Jüngere (Berlin, 1837).

HOLBERG, LEVIO, the creator of modern Danish literature, was born in 1684 at Bergen, in Norway, at the period when the latter country formed part of the Danish dominions. The ten years which succeeded his appointment, in 1718, as professor of metaphysics in the university of Copenhagen, where he had studied with the original intention of entering the church, embrace the most active literary period of his life; for during that time he composed his various satirico-heroic poems and romances, and the greater number of his numerous comedies, which are still regarded by his countrymen as the best productions of their kind in the Danish language. The creation of the national theatre in 1719 was by Frederick IV., who sent for French actors to teach Danish players the art of declamation, had led H. to try his talents in dramatic writing, and the success which attended the attempt was speedily followed by others still more felicitous. Wealth and honours poured in upon him as he advanced in years, and he received a patent of nobility in 1746. He died in 1754, bequeathing his property to the Danish Royal Military Academy of Soroe. His collected works were published in 27 volumes octavo at Copenhagen in 1826; and in 1842, an association was established in that city for the better editing of his writings, the dramatic portion of which was edited by Lehmann in 1845—1847.

H. is a first satirico-heroic poem of Peter Parna (1719), and his Niels Klim Underjordiske Reise (1741), which appeared originally in Latin, but which was speedily translated into several modern languages, rank among his best productions, although among his numerous comedies there are many that have enjoyed an almost equal popularity. Of these we may instance as especially notable for their broad humour and truth to nature, Den politiske Kondensatuer, Drys olan Buerget, Den Stadsdrømme, and Julestem.

HOLCUS. See SOFT GRASS.

HOLD is that interior compartment of a vessel throughout its length which is nearest to the keel. From the low-water deck it extends to the very bottom of the ship: it is always below the water-line, and dependent on the hatchways for ventilation and what little natural light it obtains. In merchant-vessels, the greatest portion of the cargo is stored in the hold; in men-of-war, it contains the bread-room, filled with provisions, the water-tanks for the supply of the men-of-war, a number of miscellaneous stores, such as spare masts, sails, blocks, &c. For this latter purpose, the hold is subdivided into several sections by bulk-heads. The main-hold lies between the mainmast and the poop, and the after-hold lies between the poop and the mainmast, and the fore-hold is from the bow nearly to the main hatchway.

HOLDING, the term in Scotch Law used to denote the manner in which heritable estate is held, corresponding to the English tenure (q. v.). All the land in Scotland is presumed to be held of the crown as the superior, and all persons who hold the lands are called vassals. The great proprietors are called crown-vassals, and the little proprietors, who generally hold under the crown-vassals, are called vassals. The chief holding is called feu-holding, which means that the vassal holds the land for ever, subject to a feu-duty or annual payment in money or grain to the superior. Each vassal can carry out his land into smaller feus, and sell them to sub-vassals, who extend the feudal system, and hold their lands of a superior, and so on to infinity. This is not a mere form, but enters into the substance of land transfers, and entails great expense on all landholders, because each vassal must always have his title complete, which means he must pay up the little dues and perquisites which constantly result out of this feudal principle to his superior. In England, this practice of subinfeudation was put an stop to by 18 Edw. I., and now most of the land in England is...
HOLDING OVER—HOLLAND.

neal in freehold, which means that each owner is entire master of his land, and pays fees or perquisites to nobody, not even to the crown. Besides feu-holding in Scotland there is blench-holding, which means holding that the land is free of all burdens, and the owner is entirely master of it. Formerly, there were also ward-holding and Mortification (q. v.), the latter being the holding by which churches and religious houses were held.

There is also bargue-holding, applicable to lands within Burgis (q. v.), and the transfer of bargue tenements has been lately put on a similar footing to other tenements.

HOLDING OVER, a phrase in English Law, meaning that a tenant, after a regular notice to quit, or the end of his term, still refuses to quit, and holds over. In such a case, the tenancy is held to be renewed on the same terms from year to year, if the landlord chooses not to enforce the quitting; but if the tenant himself gave the notice to quit, or the landlord demands possession at the expiration of his notice, and then the tenant refuses to quit, he is thereafter liable to double rent, or double value according as the notice to quit came from the tenant or the landlord. In Scotland, this renewal of the contract is called Tenure Rebutted (q. v.); but no liability to double rent is incurred.

HOLIDAY, in Law, means Christmas Day, Good Friday, and any other day appointed for a public fast and thanksgiving. There are other holidays usual in public offices and courts of law. When a bill of exchanging falls due on a Sunday, Christmas Day, or Good Friday, payment must be made the day previous. In Scotland, however, Christmas Day and Good Friday are not treated as holidays. In England, the courts excuse a man for not giving notice of his going abroad on any of kinds of holidays. In Scotland, the law is not only on Sunday, Good Friday, and Christmas Day, but also even on the festival days of his own religion; and though there has been no decision in Scotland on the subject, the same rule would no doubt be applied to fast-days prescribed by different sects, and a notice sent on the day following would suffice. But as a general rule, and in all other respects, it may be laid down that no sect, established or unestablished, nor any court or public body, has any power whatever to declare a holiday which has any legal effect, or which can bind the public or the rights of third parties. Nothing but an act of parliament has that effect, and not even a proclamation of the Crown would be sufficient. Hence it is that when a solemn national fast is proclaimed, which is to be put on the same footing as a Sunday, it requires a special act of parliament to make it binding on the public in matters of business.

HOLINSHED, RALPH, an English chronicler, was born of a Cheshire family, in the early part of the 16th c., and died between 1578 and 1592. The work by which he is remembered is entitled The Chronicles of England, Scotland, and Irelande (2 vols. Lond. 1577). This edition—the first—is known as the 'Shakespeare' edition, from the fact of its having supplied the greater dramatist with materials for his historical plays. It contained some passages disgraceful to Queen Elizabeth, which were omitted in the second edition of 1587. The modern edition, in 6 vols., was published in 1607—

1689, with the 'disagreeable passages' restored. H., although the principal, was not the only author of these Chronicae. He was assisted in his labours, among others, by William Harrison, who wrote the historical descriptions of the island of Ireland; and by Richard Stainhurst, who contributed an account of the condition of Ireland, to which John Hooker added the 'Compend of Ireland' (a translation from the Latin of Giraldis Cambrensis). H. has always been a great favourite with black-letter scholars, and has been freely used by modern historians.

HOLKAR, the name of a powerful Maharrta family, the members of which have at various times been formidable enemies to the British empire in Hindustan. The founder of the family was Maharao Rajo Holkar, who was born in the Deccan, 1693, and having gained by his valor the favour of the Peishwah, obtained from him the western half of Malwah, with Indore for his capital. In 1761, he joined the great league of the princes of the blood formed to bar the progress of Ahmad Shah Durani, and was present at the battle of Paniput, 14th January 1761; but as he fled shortly after the battle had commenced, he was suspected of treachery. H. was the only Maharrata chief of all who returned from that dreadful slaughter. He died in 1768, and was succeeded by his niece, Ayolah-Besie, who resigned the military power to Torkhaj Holkar. On his death in 1797, his natural son, Jeeuw Rajo Holkar, a man able, brave, and unsparing, seized Indore, but was driven out by Scindia. Such, however, was H.'s reputation for energy and ability, that part of the victorious army deserted to him, with whom, and his own troops, he displayed a signal victory on the plains of India and the Peishwah (October 1802). After fighting a long time against the British with varying success, he was compelled to conclude peace, and died insane, October 20, 1811. His son, Mulkirj Rajo Holkar I., a man nine years old, succeeded, and in 1817 declared war against the British, but his army was totally routed at Mahelpore, 21st December; whereupon he sent offers of peace, which were accepted, and his English residency was established at Indore in January 1818. He died in 1833. Martund Rajo Holkar, Huber Rajo Holkar, and Kudm Rajo Holkar, successively ruled after him; but the last of these dying without heirs, the East India Company assumed the right of nominating Mulkirj Rajo Holkar, who was educated under the auspices of the British government, and who has displayed great ability since he assumed the reins of government in 1852. On the breaking out of the mutiny in 1857, he took the field in support of the British, but the refractory behaviour of his troops prevented his rendering any effective assistance.

HOLLAND, LORD, HENRY RICHARD FOX, VASBALL-HOLLAND, third baron, F.R.S., an English statesman, descended from Lord Holland, first baron, secretary of state to George II. H. was born at Winterslow House, Wilts, in 1773, and succeeded to the title on the death of his father, the second baron, in 1774. He went to Eton, and thence to Christ Church. He was trained for public life by his celebrated uncle, Charles James Fox, and made his first speech in the House of Lords in January 1798. After the death of Mr. Fox, H. held the post of lord Privy Seal in the Grenville ministry for a few months. He then shared the long banishment of the Whigs from the councils of their sovereign. During this long and dreary interval, H., to use the language of Macaulay (who has paid an eloquent tribute to his memory), was the 'constant protector of all oppressed races and persecuted sects.' He held unpopular opinions in regard to the war with France, and signed a protest against the detention of Napoleon at St. Helena. On the other hand, he laboured to ameliorate the severity of the criminal code; made manifold war, though a West India planter, on the slave trade; threw his whole heart, though a landowner, into the struggle against the Corn Laws; and although by rank and breeding an aristocrat, laboured incessantly to extend and confirm
the rights and liberties of the subject. In 1830, he became chancellor of the duchy of Lancaster, and a member of the reform cabinet of Earl Grey, and those who now held the Macclesfield seat. He died at Holland House, Kensington, October 23, 1840. In his ample person and expressive features, he resembled his celebrated uncle.

HOLLAND, a name frequently applied to the kingdom of the Netherlands (q. v.), although in the strict sense it is applicable only to the provinces of South and North Holland (q. v.).

HOLLAND, New, the name formerly applied to the island or continent of Australia (q. v.).

HOLLAND, Parts Of. See Lincolnshire.

HOLLAND, North, a province of the kingdom of the Netherlands, lying between 52° 10' and 53° 18' N. lat., and 4° 30' and 5° 20' E. long. Area, 95556 square miles, and population (1861), 524,336. North Holland consists of a peninsula joined to the mainland at its southern extremity, and of the islands of Wieringen, Texel, and Vlieland, lying at its northern extremity. It is bounded on the W. by the German Ocean, and on the E. by the Zuyder Zee. The surface is marshy, and in many places lies below the level of the sea. The shores of the province are protected by dykes and canals intersect and drain it in every direction. The principal river is the Amstel, at the mouth of which is situated Amsterdam (q. v.). The most considerable of the many canals is the Grand Ship Canal. See AMSTERDAM.

The Haarlem Lake (q. v.), which once formed so remarkable a feature of the country, has been drained and converted into productive lands, but there still exist various small lakes or ponds in the marshy districts. The chief towns of the province are Amsterdam, Haarlem, Alkmaar, Zaanland or Saardam (q. v.).

HOLLAND, South, a province of the kingdom of the Netherlands, lying between 51° 45' and 52° 20' N. lat., and 3° 56' and 5° 10' E. long. Area, 1162 square miles, and population (1861), 626,262. It is bounded on the N. by North Holland, E. by Utrecht and Gelderland, S. by the Maas, which separates South Holland from Brabant, and W. by the German Ocean. South Holland comprises the land around the embouchures of the Rhine and Maas, which is cut up in its southern portions into several islands—viz., Vurme, Overhalksvee, and Goeree, and, in part, Zuid-Holland, Zeeland, and Noord-Holland, &c. The country is flat and low, and is broken by no elevation beyond the downs, which protect it from the sea. Streams and canals intersect it in all directions, and it abounds with lakes and with fields, or lands that have been recovered from the sea or lakes by draining. One of the most noted of these is the Biesbosch, land recovered from a marshy lake which was formed by the terrible inundation of 1421. The chief rivers are the Old Rhine, the Ijssel, Lek, Maas, and Merwede. The principal towns of South Holland are the Hague, Leyden, Rotterdam, Dort, Gorkum, Brielle, and Gouda (q. v.).

The two provinces of Holland rank among the most wealthy and productive of Europe, and their inhabitants are distinguished for indefatigable industry and habits of excessive cleanliness. The rearing of cattle, of which there are upwards of a million in North and South Holland, and the preparation of butter and cheese, constitute the principal sources of industry in the rural districts. Alkmaar in North Holland, and Gouda in South H., are the great centres of the cheese-trade. The provinces of Holland enjoy the largest share of the national commerce and wealth.

HOLLAND, Sir Henry, Bart., M.D., F.R.S., an eminent living physician, born at Knutsford, Cheshire, in 1788. He received his professional education in London, and subsequently at the University of Edinburgh, where he graduated as M.D. in 1811. He then spent two or three years in the east of Europe; and in 1815, after his return to England, published his Travels in Abroad. passengers. In 1822 he was elected Fellow of the Royal College of Physicians, a distinction at that time very rarely conferred upon a Scottish M.D. In 1840, he was appointed physician-in-ordinary tc the Prince Consort, and in 1852, physician-in-ordinary to the Queen. In the following year, he was made a baronet. In 1856, the university of Oxford conferred on him the honorary degree of D.C.L., and he has likewise received the degree of LL.D. from the university of Cambridge, Massachusetts. In 1840, he published a volume entitled Medical Notes and Reflections, consisting of 34 essays upon various of the most interesting departments of medicine and psychology, which has passed through several editions. In 1852, his Chapters on Mental Physiology appeared, which are expansions of essays in his former work which treated of a particular part of human physiology which comprises the reciprocal actions and relations of mental and bodily phenomena. His Essays on Scientific Subjects, published in 1856, and embracing the consideration of so many of the most profound subjects in the wide domain of physics, shew that if his special studies had taken a different direction, he would have attained as great a fame as a natural philosopher as he now enjoys as a physician.

HOLLANDS. See Gin.

HOLLOW-WARE. A trade term, applied to such common iron utensils as are hollow, such as caldrons, sauce-pans, kettles, &c.

HOLLY (Ilex), a genus of trees and shrubs of the natural order Aquifoliaceae, chiefly natives of temperate climates; with evergreen, leathery, shining, and generally spiny leaves; small flowers, often 5-7-angled, in clusters, with 4-5-calix corolla, 4 or 5 stamens, and the fruit globose and fleshy, with 4 or 5 stones (nut). The Common H. (I. aquifolium), the only European species, and a native also of some parts of Asia, is a well-known ornamental tree, native in England, and in many parts of northern Europe, where it is often cultivated in large quantities. It is found as a native plant in Scotland, although Britain is in nearly its northern limit; and it attains a greater size and displays greater luxuriance in the northern than in the southern parts of its geographic range, often appearing in the former as a tree of considerable size, 20 to 30 feet high, whilst in the latter it is generally a mere bush. It prefers light soils. There are numerous varieties of H. produced, or at least perpetuated by cultivation, exhibiting great diversity of the leaves of which the Hedgehog H. may be mentioned as extremely sinuous and twisted, whilst others are prized for their colour, golden, silver-blotched, &c. The flowers of the H. are white, axillary, nearly umbellate; the fruit small, scarlet, rarely yellow or white. The abundance of the fruit adds much to the ornamental character of the tree in winter, and affords food for birds; but to man it is purgative, emetic, and diuretic, and in larger quantities poisonous. The leaves are inodorous, have a much stagnating bitter

383
and some that nauseate taste, and have been used medicinally in cases of gout and rheumatism, as a diuretic and also as an astrigent and tonic to correct a tendency to diarrhoea, &c. The leaves and small branches, chopped, are sometimes used for feeding sheep in severe winters. The root and bark are emollient, expectorant, and diuretic.

Birdlime (q. v.) is made from the inner bark. The wood is almost as white as ivory, very hard and fine-grained, and is used by cabinet-makers, turners, musical instrument-makers, &c, and sometimes for wood-engraving. Handles of tools and handles of nets and sea-pots are very often made of it. The H. is often planted for hedges, as it bears clipping well, and makes an excellent fence. A H. hedge may either be kept low, or, as is the case at Tynemouth, in East Lothian, allowed to grow to the height of 20 or 30 feet. In the gardening of former days, hollies were often clipped into fantastic shapes. The name H. is said to be derived from the use of the branches and berrys to decorate churches at Christmas, from which the tree was called Holy Tree.—Numerous other species of H. are found in North America, most of them in swampy situations, in South America, Nepal, Japan, and other parts of the world; some of which have been not unfrequently introduced as ornamental trees and shrubs in Britain.—Matte (q. v.), or Paragonum Tett, is the leaf of a South American species of H. (I. paragonensis).

HOLLY SPRINGS, a village in Northern Mississippi, United States, America, on the Central Railroad 25 miles south of its junction with the Memphis and Charleston line. It is the principal town in Northern Mississippi, and contains several churches, four academies, a bank, and two or three newspapers, with a large trade in cotton and merchandise. Pop. about 4300.

HOLLYHOCK (Althaea rosae), a plant of the natural order Malacca, commonly referred to the same genus with the Marsh Mallow (q. v.). It has a tall, straight, hairy stem; heart-shaped, crenate, wrinkled, 5-7 angled leaves, and large axillary flowers almost without stalks; the leaves diminishing into bracts, and the upper part of the stem forming a spike; the petals hairy at the base. The H. is a native of India, the south of Europe, &c., is to be seen in almost every garden in India, and has been much cultivated in gardens in England from a very early period. At present, it is a favourite flower, and varieties, the result of cultivation, are very numerous. It varies much in the color of the flowers, the shape of the semi-double and single-doble varieties are common. It is an autumnal flower, continuing till the frost sets in. It is a biennial or perennial plant. The stem rises to a height of 8-15 feet, unbranching, or nearly so. The fibres of the plant have been made into yarn, but it is not yet certain if it is really valuable for cultivation on this account, or for the manufacture of paper. It is not improbable that it might be cultivated with advantage to afford green fodder for cattle, which are very fond of its leaves, and the leaves are produced in great abundance if the plant is prevented from flowering. The flowers are mucilaginous and demulcent, and are sometimes used like those of mallows and marsh mallows. The leaves yield a fine blue dye.—The Chinese (Capitata) is a good species.

HOLMES, Oliver Wendell, M.D., an American physician and author, was born at Cambridge, Massachusetts, August 29, 1809. In 1829, he graduated at Harvard College, and entered upon the study of law, but soon abandoned his father's profession for medicine. He studied in Italy, graduated M.D. at the College of medicine in 1836, and two years after was appointed professor of anatomy and physiology in Dartmouth College; and in 1847, transferred to the College of Medicine, New York. At his death, the sum of $2000 were subscribed as a testimonial of which is at Boston, where he has since resided. Dr. H. is not only a man of science, but a humorous and satirical poet of much ability. Several of his lyrics also are among the most exquisite produced in America. Most of his prose have been delivered before college literary societies, as Poetry, a Metropolitan Essay; Terpsichore; Urania; and Astron. In 1857 he contributed his Autocrat of the Breakfast Table, a connected series of prose essays, to the Atlantic Monthly, which was followed by The Professor at the Breakfast Table, which has the added interest of a story. His last work is the singular romance entitled Elsie Venner (1861). Dr. H. is also one of the most popular of public lecturers. Of medical writings may be mentioned three, Bogats's Prize Dissertations, Lectures on Homoeopathy and on Kindred Delusions, A Report on Medical Literature, besides many articles in professional periodicals. He combines wit, humour, poetry, science, and philosophy.

HOLOCAUTHUS, a genus of fishes, of the family Chatalodontidae (q. v.), remarkable for the great beauty and symmetry of their colours, and for their excellence as articles of food. They have the general form and other general characters of the Chatalodontidae, a single dorsal fin, and a large spine on the gill-cover. They are natives of the seas of warm climates. H. imperator is one of the most esteemed fishes of the East Indies, recalling the salmon in flavour. Its greatest size is about 15 inches long; its colour is deep blue, with numerous narrow bands of orange, the pectoral fins black, the tail bright yellow. It is known in some parts of the East as the Emperor of Japan.

HOLOCAUST. See SACRIFICE.

HOLOFERNES. See JUDITH.

HOLOGRAPH (Gr. holog, all, and graph, writing), deed or writing, in Scotch Law, means a writing in which the author or maker does his own penmanship. Considerable privileges are given to this species of writing, whereas, in England and Ireland, it is in general utterly inoperative whose penmanship is used, provided the party sign or seal the writing or deed. In Scotland, if a person execute his will or a deed in holograph, this dispensation is not required, but if he merely signed a paper written by another hand, for no witnesses are required to attest holograph deeds or testaments. If the handwriting, however, is disputed, evidence must be given as to whose handwriting it is. In England, it is quite immaterial whether a person writes out his own will or not; in either case there must be two witnesses. So in the case of holograph missive writings and accounts, there is a difference as to the period of prescription applicable in Scotland, but in England there is no distinction merely on this ground. The distinction between holograph and other deeds also prevails in the law of France and other continental countries.

HOLOPYTHUS (holos, all, and pyth, wrinkle), a remarkable genus of fossil gilled fishes, so named from the wrinkled appearance of the enamelled scales. They were of large size, some species probably reaching the length of 12 feet. The surface of the body was covered with large tuberculated plates, like those of the crocodile, and the body was completely encased in large scales, more like those of a reptile than a fish. Some scales have been found measuring 3 inches in length by 2 a breadth, and a full eighth of an inch in thickness. They were composed internally of porous
Holoptychius Nobiliissimus (Agassiz).

Clasbbenie, on the Firth of Tay, by Mr. Noble; it now forms part of the British Museum collection. It is a foot across by two feet and a half long without the tail, which is wanting. It is nearly perfect, lying on its back, with the scales and the ventral fins in their original position. The genus is peculiar to the Old Red Sandstone and Carboniferous Measures; eight species being found in the former, and nine in the latter. It has been proposed to confine the name Holoptychius to the fossils of the Old Red Sandstone, and to give that of Rhizodus, which Owen applied to the teeth remains before their connection with the fish was known, to the Holoptychians of the Coal Measures, which have the outer row of teeth more robust and obtuse, and the inner set longer, sharper, and more slender than in the older species.

HOLOTHURIA, a genus of Echinodermata

(q.v.), the former limits of which are now those of a family, Holothuridae, divided into numerous genera.
HOLSTERS—HOLY ISLAND.

The Holy Coat of Treves.

Concealed from the Normans in the 9th c. in crypts; but the Holy Coat was rediscovered in 1196, and then solemnly exhibited to the public gaze, which did not take place again till 1512, when multitudes flocking to see and venerate it, Leo X. appointed it to be exhibited every seven years. The Reformers and wars prevented the regular observance of this great religious festival; but it was celebrated in 1819, and was attended by a concourse of no less than 277,000 persons; and in 1844 by still greater multitudes, whilst miraculous cures were constantly asserted to be performed by the precious relic. The exhibition of the Holy Coat in 1844 is otherwise memorable for the reaction which it produced, leading to the secession of Rongé and the German Catholics from the Church of Rome.—For further information see The Book of Days, published by W. & R. Chambers.

HOLY ALLIANCE, a league formed after the fall of Napoleon by the sovereigns of Russia, Austria, and Prussia, nominally to regulate the relations of the states of Christendom by the principles of Christian charity, but really to preserve the power and influence of the existing dynasties. Most of the other European rulers acceded to it, and the treaty was formally made public in the Frankfort Journal, February 2, 1816. It was in virtue of this league that Austria, in 1821, crushed the revolutions in Naples and Piedmont, and that France, in 1823, restored absolutism in Spain. Subsequently, both France and England seceded, after which it became a mere nomina umbra. A special article of the treaty excluded for ever the members of the Bonaparte family from any European throne!

HOLY COAT, a relic preserved with the greatest reverence in the cathedral of Treves, of which city it is esteemed the greatest treasure. It is alleged to be the seamless coat of our Saviour, and to have been discovered in the 4th c. by the Empress Helena, in her memorable visit to Palestine, and by her deposited at Treves. The Treves relics were

HOLY FAMILY, the name given, in the language of art, to every representation of the infant Saviour and his attendants. In the early part of the middle ages, when the object in view was to excite devotion, the Virgin and Child were usually the only persons represented. At a later period, Joseph, Elizabeth, St Anna (the mother of the Virgin), and John the Baptist, were included. Some of the old German painters have added the twelve apostles as children and playfellows of the infant Christ, as they are said to have been by the legends. The Italian school, with its fine feeling for composition, was the first to recognise of how many figures the group must consist, if the interest is to remain unaltered, and be concentrated on one figure, whether that figure be the Madonna or the Child. Two masters are pre-eminent in this species of representation—Leonardo da Vinci and Raphael.

HOLY GHOST, or HOLY SPIRIT, in Ortho
dox Theology, the third person of the Trinity (q. v.), proceeding from the Father and the Son, of one substance, majesty, and glory with the Father and the Son, very and eternal God. His distinct personality is believed to be attested by a multi-
tude of passages in Scripture, which it is unneces-
sary to quote. One may suffice.—But when the Comforter is come, whom I will send unto you from the Father, even the Spirit of truth, which pro-
cedeth from the Father, he shall testify of me (John xiv. 26). 'The 'Procession' (q. v.) of the Spirit is the subject of one of the chief differences between the Eastern and the Western or Latin Churches. He is essentially a spirit of holiness, and his grand function is to apply to the hearts of men the benefits of Christ’s death, to work in them, first, a belief of the truth as it is in Jesus, and then to sanctify them by that truth.

HOLY GRASS (Hierochloe borealis), a grass about a foot high, with a brownish glossy panicle. It is found in the most northern parts of Britain, and in the north of Europe. It has a sweet smell, like that of vernal grass; and in Iceland, where it is plentiful, it is used for scenting aptments and clothes. In some countries, it is strewn on the floors of places of worship on festival-days, whence its name.

HOLY ISLAND, or LINDISFARNE, a small island of England, belonging to the county of Northumberland, and situated about ten miles south-east of Berwick-upon-Tweed. It is about four miles long, and two miles broad, and is connected with the mainland by sands three miles in extent, which can be traversed at low-water by vehicles of all kinds. Pop. of parish, 614; but including the chapelries of Kyleo, Aucroft, and Tweedmouth, all in the ancient parish, and called Tweedmouth—4049. On the south coast is the village of Holy Island, finely situated, and now much resorted to by summer visitors. On the island are several ruins, the chief of which are the extensive and
sombre-looking remains of the famous Abbey of Linsifarne, originally a Saxon edifice; there is also an ancient castle, now fortified and occupied by a garrison of artillery. In former times, H. I. was the seat of a bishopric.

HOLY LAND. See PALESTINE.

HOLY PHIAL, or SAINTE AMPOLLE. ORDER OF, the name of an order of knighthood which formerly existed in France, and was composed of four persons, usually the first in point of rank, family, and fortune in the province of Champagne, and styled the "St. Phila Ampolle." At the coronation of the French kings, they were delivered to the Dean, Prior, and Chapter of Rheims, as hostages for the fulfilment of the engagements entered into by the great officers of the crown to return the holy phial in which the coronation oil was kept, and which, according to the legend, was brought from heaven by the Holy Ghost under the form of a dove, and put into the hands of St. Louis at the Investiture of Clovis—an enormous crowd having prevented the messenger from bringing in time that which had already been prepared. The peculiarity of this order was that the knights were only knights for a day. Their badge was a cross on a shield divided white, cantoned with four fleur-de-lis, and on the cross a dove descending with a phial in its beak, and a right hand receiving it.

HOLY PLACES, HOLY SEPULCHRE. Under the head JERUSALEM (q. v.) are enumerated many localities which, from the memories associated with them, must be full of solemn interest for every religious mind; but the name Holy Places of Jerusalem more strictly designates the group of sacred places of which the Church of the Holy Sepulchre is the centre, and which are supposed to comprise the sites of the chief events of our Lord's passion, death, and burial: Gethsemane, the Supper-room, the Church of the Ascension, the Tomb of the Virgin, &c.

In the article JERUSALEM, the general topography of the ancient and modern city is briefly described. The so-called Church of the Holy Sepulchre stands within the modern city, on the north side of the Latin quarter. It is a Byzantine building, in the centre of a spacious court. Under the great dome of the church stands the Holy Sepulchre, which is of an oblong form, fifteen feet by ten, and is surrounded by a rich ceiling, decorated with mosaics. One of the pillers on the wall. A circular hall surrounds the space beneath the dome. Around this circular hall are oratories for the Syrians, Copts, and Maronites; and above it is a series of galleries, which are similarly appropriated. In the body of the church are the chapels of the Greek, Latin, and Armenian Christians, the church as a whole being maintained by the Ottoman authorities in the condition, as it were, of a common meeting-ground for all the Christian communities, as the rivalry of the several religious bodies constantly lead to angry controversy, and not unfrequently to sanguinary conflicts. Opposite the entrance of the enclosure is a somewhat elevated marble niche, which is called the Sibylla Nupta, and is shown as the stone on which our Lord's body was anointed before entombment; and above it is an elevation approached by steps, which is the traditionary Mount Calvary, and on which now stands a rich dome-shaped building, floored with rich marbles, in the crypt of which is the cavity supposed to have been formed by the ejection of the cross. The street by which this site is approached, from the direction of the ruins of Herod's palace, on the north side of the city, is the principal street of the Latin quarter, and is called by the Turks Har-rid-el-Ab Dam, and by the Christians the Via Dolorosa, as being the supposed route of our Lord from the hall of judgment to Calvary.

Such is the traditional view as to the locality, not only of these leading events of our Lord's history, but also of many others of minor importance, and less prominently noticeable. For a long course of age, the Christian world has acquiesced in this view of the topography of the Holy Places; but since the beginning of last century, doubts have been entertained as to its correctness; and in later years, the question has been discussed with much learning, although with little positive, or at least conclusive result. About the year 1759, a German, named Korte, who had visited Jerusalem, and explored the locality, published a work, calling the authenticity of the received system of the topography into question. The doubts expressed by him have been repeated at intervals ever since his day, and especially by the celebrated American critic, Dr Robinson, author of Biblical Researches in Palestine, which subsequent investigations, to have exhausted the evidence, on one side of the question, at least so far as the remains of the ancient city had at that time been explored.

Dr Robinson distinctly affirms the impossibility of reconciling the sacred places mentioned in our Lord's parables with the plain requirements of the gospel history; but he fails himself to point out a scheme of topography which may be substituted for that which has been traditionally received. More recent critics, and especially James Ferguson, in his Essay on the Ancient Topography of Jerusalem, agreeing with Dr Robinson in rejecting the received topography, contends against him that the true site of the Holy Sepulchre may be accurately determined, and that it is no other than the Mosque of Omar, or, as the Mohammedans call it, the Dome of the Rock. This he holds to be the identical church which Constantine erected over the rock which contained the tomb of our Lord. The latest biblical traveller in Palestine, Dr Stanley, has left the question undecided. It is beyond the scope of this work to discuss such a subject. We can but refer the reader to the chief authorities on each side of the controversy. It is only upon the heads of our future explorers may throw much light by skilful and judiciously conducted excavations. The works at present about to be undertaken under the authority of the Russian government are looked to with much interest, on the one side, by our followers, as Biblical Researches in Palestine, Smith's Dictionary of the Bible, article 'Jerusalem' (Ferguson); Essay on the Ancient Topography of Jerusalem, by the same author. On the other, William's Holy City, Rammer's Beiträge zur Bibl. Geographie, Sepp's Forschungen eines Deutschen Reisenden in Jerusalem, Schaffer's Aehliche Lage des heiligen Grolzes.

HOLY SEPULCHRE. KNIGHTS OF THE, an order of knighthood instituted, probably by Pope Alexander VII, for the care and defence of the Holy Sepulchre, and the relief and protection of pilgrims. The pope was originally the grand-master, but he subsequently ceded his rights to the Guardian Father of the Holy Sepulchre, who, by the rules of the order, is to have the whole of noble descent; they were bound to bear mass daily, to fight, to live, and to die for the Christian faith, &c. In return for these duties, the knights had the most unusual and extraordinary privileges conferred on them: they were exempt from taxation, could marry, and yet possess church property, legitimate bastards, and cut down and bury the bodies of criminals who had been hanged. On the recapture of Jerusalem by the Turks, the knights retired to Italy, and settled...
HOLY WATER—HOLYHEAD ISLAND.

at Perugia. After a temporary union with the Hospitalers, the order was reconstituted in 1814 both in France and in Poland, and is now maintained within a very small circle of knights elected by the Guardian Father from the most respectable pilgrims who come to Jerusalem.

HOLY WATER, in the Roman Catholic, as also in the Greek, Russian, and Oriental churches, signifies water blessed by a priest or bishop for certain liturgical uses. Water is the element of its own nature, a fitting symbol of purity; and accordingly, in most of the ancient religions, the use of unstraw or purifying water not only formed part of the public worship, but also, in place of the personal acts of sanctification prescribed to individuals. The Jewish law contained many provisions to the same effect; and our Lord, by establishing baptism with water as the necessary form of initiation into the religion instituted by him, gave his sanction to the use, which, from its universal acceptance among mankind, appears to be a relic of the primeval natural revelation. The usage of sprinkling the hands and face with water before entering the sanctuary, which was prescribed in the Jewish law, was retained, or at least very early adopted, in the Christian church. It is expressly mentioned by Tertullian in the end of the 2nd century. And that the water so employed was blessed by the priests among others, from St Jerome, and from the apostolical constitutions. Although it is difficult to fix the precise time, it cannot be doubted that the practice of mingling water with the water is of very ancient origin (see Canon 20, De Consacr. Dist. iii.). In the Western Church, there is a solemn blessing of water in the service of Holy Saturday, but the ceremonial is repeated by the priest whenever it may be necessary, to rinse also the faithful. Instructed Catholics regard the use of holy water chiefly as a means of suggesting to the mind the necessity of internal purity; and although it is supposed to derive from the blessing a special efficacy for this end, yet this efficacy is held to be mainly subjective and of a character entirely distinct from that ascribed to the sacramental rites of the church. In the reformed churches, the use of holy water is regarded as unscriptural and superstitious.

HOLY WEEK, the week immediately preceding Easter, and specially consecrated to the commemoration of the Passion of Our Lord. In English use, it is also called 'Passion Week' (a name appropriated, in Roman use, to the week before Palm Sunday). This institution is of very early origin, and the name Holy Week is but one of many by which its sacred character has been described. It was also called the 'Great Week,' the 'Silent Week,' the 'Week of the Holy Passion,' the 'Vacant Week,' the 'Penitential Week.' In the Roman Catholic Church, the special characteristics of the celebration of the Holy Week are increased solemnity and gnom, penitential rigor, and mourning. If any of the ordinary church festivals fall therein, it is transferred till after Easter. All instrumental music is suspended in the churches, the altars are stripped of their ornaments, the pictures and statues are veiled from public sight; manual labour, although it is no longer entirely prohibited, is by many persons voluntarily suspended; the rigor of fasting is redoubled, and alms-deeds and other works of mercy sedulously enjoined and practised. All church services of the week, moreover, breathe the spirit of mourning, some of them being specially designated to this end. The solemn consecration of the oil or chrism used in baptism, confirmation, orders, and extreme unction, the washing of pilgrims' feet, and the teantrum, To Holy Week belongs the solemn blessing of fire and of the water of the baptismal font; and from the earliest times, it was set apart for the baptism of catechumens, and for the ordination of candidates for the ecclesiastical ministry. From the fire solemnly blessed on this day is lighted the Paschal Light, which is regarded as a symbol of Christ risen from the dead. This symbolic light is kept burning during the reading of the gospel at mass throughout the interval between Easter and Pentecost. See Wetser's 'Church Lexicon,' art. 'Charwoche.' It must be added, however, that in many instances the primitive institution of the Holy Week was perverted, and that what is now and almost universally regarded for purposes of devotion and recollection, was turned into an occasion of amusement not unfrequently of a very questionable character. Such abuses are now universally disowned and by the ecclesiastical authorities.

In the Protestant communions, there is no special solemnisation of the Holy Week, with the exception of Good Friday (q. v.), which is observed in some of them.

HOLYHEAD, a seaport, parliamentary borough, and market-town of North Wales, in the county of Anglesea, is situated on a small island of the same name, 244 miles west-north-west of Bangor, and 272 miles north-west of London. Although recently much improved, it is still a primitive, irregularly built town. It is the station of the mail steam-packets to Dublin, from which it is distant about 69 miles. The harbour of H., which is almost dry at low tide, is formed by a pier about 1000 feet in length, running north-east from an islet called Salt Island, which is connected with the mainland by a swivel-bridge. Few manufactories are carried on here. Pop. (1861) 6190, who are employed in the coating-trade, and in ship-building and rope-making. The harbour of refuge now (1862) being constructed here, will, when completed, enclose an area of about 316 acres, with a depth of upwards of six fathoms. H. unites with Amlwch, Beaumaris, and Llangefni in sending a member to the House of Commons.

HOLYHEAD ISLAND, a small island of North Wales, lies west of the island of Anglesea, and forms part of the county of that name. Its greatest length is seven and a half miles, and its greatest breadth about three and a half miles. Area, about 6000 square acres; pop. 8868. H. I. is separated from Anglesea by a narrow sandy strait crossed by a bridge, and is connected by the Chester and Holyhead Railway, which are formed by embankments or causeways, arched in the centre, to admit of the passage of the water. The island, which comprises some good pasture-ground for sheep, as well as a proportion of arable land, is for the most part rocky and barren. On the north-west coast are two islets, the North and South Stacks, the latter with a lighthouse, the light of which is visible at twenty miles distance. The picturesque and singular scene of the Passion of our Lord. The days thus specially solemnised are Palm Sunday, Spy Wednesday, Holy (or Maundy) Thursday, Good Friday (q. v.), Holy Saturday. Holy Thursday (called also Maundy Thursday, from Mandatum, the first word in one of the church services of the day), in the Roman Catholic Church, is specially designed as a commemoration of the Last Supper, and of the institution of the Eucharist. But there are several other occasions consecrated to the days, as a solemn consecration of the oil or chrism used in baptism, confirmation, orders, and extreme unction, the washing of pilgrims' feet, and the teantrum, To Holy Week belongs the solemn blessing of fire and of the water of the baptismal font; and from the earliest times, it was set apart for the baptism of catechumens, and for the ordination of candidates for the ecclesiastical ministry. From the fire solemnly blessed on this day is lighted the Paschal Light, which is regarded as a symbol of Christ risen from the dead. This symbolic light is kept burning during the reading of the gospel at mass throughout the interval between Easter and Pentecost. See Wetser's 'Church Lexicon,' art. 'Charwoche.' It must be added, however, that in many instances the primitive institution of the Holy Week was perverted, and that what is now and almost universally regarded for purposes of devotion and recollection, was turned into an occasion of amusement not unfrequently of a very questionable character. Such abuses are now universally disowned and by the ecclesiastical authorities.

In the Protestant communions, there is no special solemnisation of the Holy Week, with the exception of Good Friday (q. v.), which is observed in some of them.
HOLYROOD—HOMAGE

bellowed out by the action of the sea into magnificent caves, which are the haunt of innumerable sea-birds. Principal town, Holyhead (q.v.).

HOLYROOD, the royal residence of the kings and queens of Scotland. In 1320, David I. of Scotland founded at Edinburgh an abbey of canons regular, of the order of St Augustine. It was dedicated in honour of the Holy Cross or Rood, which was brought to Scotland by St Margaret about the year 1050, and became the royal burying place of the kings of Scotland.

The Black Rood of Scotland (q.v.), as it was called, fell into the hands of the English at the battle of Neville’s Cross in 1346, and as its history passed from remembrance, a faile sprung up telling how King David was prevailed upon by his young nobles to go a hunting on the solemn festival, by which the church yearly commemorated the finding of the Holy Cross at Jerusalem; how the chase lay through the forest, which in those days encircled Arthur Seat, and stretched almost to the gates of Edinburgh; how the king, in pursuit of a wild hart, outdrove all his companions; how at the foot of Salisbury Crags this hart turned to lay, and overleaped the king’s horse; how it rushed at the king, threatening him with instant death, a cross, as if from between its antlers, miraculously slid into the king’s hands; how at the sight of it the king’s heart did and vanished from the king, warned by a vision in his sleep, resolved to build a monastery in honour of the Holy Rood on the spot where his life had been so preternaturally saved.

When this legend was invented, apparently about the year 1419, it had been forgotten that the first site of the abbey was not at the foot of Salisbury Crags, but within the walls of the castle, whence it was not finally removed until after the year 1744, to the eastern extremity of the Canongate, as the little burial came to be called, which the canons erected between their abbey and the king’s barge of Edinburgh. The abbey was burned by the English in 1555, in 1544, and in 1547. Before it could be restored after these last conflagrations, the Reformation arrived, when the ruins of the choir and transepts were taken down to repair the nave. This was used as the parish church of the Canongate from about 1560 till 1672, when it was turned into the chapel-royal.

In 1587, James VI., having built another parish church for the Canongate, set the nave of the abbey church apart for the Roman Catholic service, and had this church fitted up with stalls for the clergy of the Thistle. It was plundered and burned by the mob at the Revolution in 1688, and remained in neglect until 1738. In that year it was repaired and roofed, but the roof was too heavy for the walls, and it fell in 1768, crushing the pillars of the north aisle, and otherwise injuring the building.

The abbey of H. early became the occasional abode of the Scotch kings. John Balliol held a parliament within its walls in 1295. James II. was born in it, crowned in it, married in it, buried in it. The foundations of a palace, apart from the abbey, were laid by James IV., whose splendid vaults with the Prince Regent of England were celebrated here in 1603. Edinburgh had now become the acknowledged capital of Scotland, and H. henceforward was the chief seat of the Scottish sovereigns. Queen Mary took up her abode in the palace when she retraced from France in 1561. Here, in 1566, Rizzio was torn from her side, and murdered. Her son, King James VI., dwelt much in H. before his accession to the throne of England in 1603. He revisited it in 1617. It was garrisoned by Cromwell’s troops in 1650, but the Scottish king had been driven out by the English in 1650, when the greater part of it was burned down. It was rebuilt by King Charles II., from the designs of Sir William Bruce of Kinnos, between 1671 and 1679. In 1745 and 1746, it was occupied in succession by Prince Charles Edward, and by the Duke of Cumberland. It sheltered the Count d’Artois (afterwards King Charles X. of France) from 1755 to 1799, and again from 1831 to 1835. King George IV. held his court in it in 1822. Since that time much has been done to make it a suitable residence for sovereigns, and in recent years the Queen has visited it almost every summer.

The oldest part of the palace is the north-west tower, founded by King James IV., about 1500, and completed by his son, King James V., who died in 1542. It was somewhat modernised in 1671—1679; and the roofs, if not the floors also, were renewed by King Charles I. (1625—1649), whose cipher they bear; but otherwise the disposition of the rooms seems to be much the same as in the days of Queen Mary. It need scarcely be added, that the furniture is much more recent, and that the articles shown as relics of Mary and her court are wholly spurious.

The palace, with its precincts and park, is a sanctuary for debtors. In England, the same privilege extends to royal palaces to this extent, that no writ of legal process can be executed within their bounds; but in Scotland it is practically as only a protection to the servants of the palace; and no means exist for insolvent persons taking lodgings in a privileged place there or elsewhere, and avoiding imprisonment, in so systematic a way as is competent to residents within the precincts of Holyrood Palace, where there is ample accommodation. The precincts comprehend the adjoining park and the hills of Arthur’s Seat and Salisbury Crags. Refuge debtors must procure certificates of protection within twenty-four hours from the proper official within the bounds. Taking refuge within the sanctuary is considered disreputable, and from this cause, as well as from recent meholations in the laws affecting debtors, the practice is greatly fallen off. It is to be added, that the sanctuary of Holyrood shelters debtors to the crown.

HOLYWELL, a municipal and parliamentary borough, and market-town of North Wales, in the county of Flint, and 41 miles north-west of the town of that name, is situated on an eminence on the line of the Holyhead and Chester Railway, and near the south-western shore of the estuary of the Dee.

It is the centre of an immensely valuable mineral district, and is the seat of numerous establishments for lead and copper refining, manufacturing shot, zinc, &c. There are also manufactures of earthenware, flannels, and galloons, paper, and Roman cement; coal and lead mines, and limestone quarries, are worked. This borough unites with those of Flint, Mold, &c., in returning a member to parliament. Pop. (1861) 5333.

H. is now one of the most important and flourishing towns of North Wales. It owes its origin to the renowned Well of St Winifred, which is estimated to deliver twenty-one tons of water per minute, and is said to be the most copious spring in Britain. Its waters were at one time believed to be efficacious in curing diseases, and were visited by great numbers of pilgrims.

HOMAGE is the service or show of respect due from a knight or vassal to his lord in feudal times. The word is derived from the form of expression used in doing the service, which was—jeo digne nostrae home—I become your man. Since the abolition of tenures, the word has no substantial legal meaning in the United Kingdom, except in a metaphorical sense as to copyholds, to denote the kind of acknowledgment made by a tenant to the lord of the manor. The homage jury consisted of the tenants who did
Homage, and their presence was necessary to attest some acts. Homagnium redtide was the expression, now obsolete, signifying a solemn renunciation of host and refreshment to the Lord, and a draught of him. The word homage is not used in Scotch law, though the feudal system is not obsolete in Scotland in many other respects.

**HOMALOPTERA** (Gr. level-winged), the name given by some entomologists to a small order of insects, which has been more generally regarded as a division of the order Diptera. The H. have also been called Pupifera, from the remarkable circumstance that the larvae are hatched within the body of the mother, and remain there till they have passed into the pupa state. Some of the H. are wingless. Examples of this order are found in the Forest Fly (q. v.), and in those extraordinary parasites of bats called Mycteris. All the H. are parasites.

**Homeburg Vor Der Höhe,** a pleasant little town, capital of the landgraviate of Hesse-Homburg (q. v.), is situated at the foot of the Taunus Mountains, nine miles north-west of Frankfurt-on-the-Main. It has beautiful environs, easily occupied with judicial and literary centres of its miners, waters and gambling-saloons. The waters are considered very effective in cases of disordered liver and stomach. They are five in number, and one of them, the Elizabeth, contains more carbonic acid than any saline spa known. About 400,000 bottles of the ‘waters’ of H. are annually sent away. Pop. 5000.

**HOME, Henry (Lord Kames),** an eminent Scottish lawyer and author, was born in 1696 at Kames, in Berwickshire. Destined by his friends for the law, he was apprenticed in 1712 to a writer to the signet; but he afterwards decided on adopting the highest branch of his profession, and qualified himself for it mainly by private reading and attendance at the courts. Entering the bar in 1723, he was raised to the bench in February 1752, assuming the title of Lord Kames, and was made one of the Lords of Justiciary in 1763. He died 27th December 1782. In 1728, he published Remarkable Decisions of the Court of Session from 1716 to 1728. The materials of this work were in 1741 embodied in his Dictionary of the Decisions of the Court of Session during its whole history, which, though now superseded, was of great use to lawyers at the time, and was thought worthy of being continued by Lord Woodhouselee.

He is best known, however, by his Essays on the Principles of Morality and Natural Religion (1751), containing a solution of the question of human freedom, which brought on him the suspicion of infidelity, and raised considerable controversy in the courts of the church and through the press; his Introduction to the Art of Thinking (1711); and above all, his celebrated Principles of Criticism, the work on which his fame now chiefly rests. In 1773 appeared his Sketches of the History of Man, which may be found entertaining, but are now of very little scientific value. Though thus hasty occupied with judicial and literary labours, he took a very active interest in agriculture and commerce, and wrote a useful tract on the former, entitled The Gentleman Farmer, being an Attempt to improve Agriculture by subjecting it to the Test of Reason. The last of his philosophical Essays, Thoughts on Education (1781), was written in his 84th year. See Lord Woodhouselee's Memoirs of the Life and Writings of Home (2 vols. 4to, Edin. 1807).

**Homeyln, Rhaia maculata**, a species of Ray (q. v.), common on the south coast of England, and plentiful in the London market, but comparatively rare on the east coast of Scotland.

In form and appearance, it more nearly resembles the skate than the skink. On some parts of the British coast, the H. is called Sand Ray. It is also known as the Spotted Ray.

**Homeyln, the greatest name in the history of epic poetry, and who stands as high in that department as Shakespeare does in the drama, has come down to us in modern times unfortunately as little better than a name, and presents materials for biography as scanty as those which he offers for criticism are rich. We are not, however, forced to go to such lengths of doubt in his case as Aristotle did in the case of Orpheus, denying that such a man ever existed; for though the Germans, since the days of Heyne, Wolf, and Niebuhr, have indulged themselves in every variety of historical scepticism, and reduced H., as well as Cædesius and Hercules, to mere ‘symboles,’ the more sober genius of British criticism, with which the moderate views of the last later Germans coincide, has pronounced an almost unanimous verdict in favour of the historical reality of the author of the Iliad and the Odyssey. Not that any reliance is to be placed on the details of the old Greek lives of H., which are manifestly fictitious; but the internal evidence of the poems themselves leads to the belief in an authorship such as agrees substantially with the kernel from which these very ancient legendary traditions were developed. The central fact in which all
HOMER.

These traditions agree is, that the author of these poems was an Asiatic Greek; and though other places are named, the greatest amount of legendary evidence clearly points to Smyrna as the city which had the honour of giving birth to the father of epic poetry. The dialect in which the Iliad and Odyssey are written—this is the very Greek of which was afterwards used in the same region by Herodotus, the father of History, and by Hippocrates, the first and greatest of Greek physicians—and the grace of its words, the frequent mention of the strong north-west wind blowing from Thrace, plainly indicate the west coast of Asia Minor as the familiar residence of the poet. The chronology of the Homeric poems, both as respects the great central event which they celebrate—the Trojan war—and the age of the poet himself, is much more doubtful; but it is quite certain that H. lived considerably before the recognition of a regularly recorded date of records among the Greeks—that is, before the year 776 B.C., the commencement of the calculation by Olympiads. The date given by Herodotus for the age of H.—400 years before his own time, that is, about 850—has been generally adopted by the entire want of any reliable foundation for chronology in those early times, we must not seek an accuracy in this matter beyond what was attained by the Greeks themselves, and allow a free margin of at least 1000 years from the time of Solomon (1000 B.C.) downwards, during which the singer of the Iliad and Odyssey may have flourished. To throw him further back than the earliest of these dates would be inconsistent at once with the historic elements in the midst of which his poems move, and with the style of the language which he uses; for this exhibits a luxurious freedom, a rich polish, and an exquisite euphony, which removes it far from that roughness and clumsiness which is wont to characterize languages in their earliest stage of literary development. The Ionic dialect used by H. is, in fact, a highly cultivated speech of the old Hellenic stock, and which was in the poet’s hands as perfected for the highest poetical purposes as he had to remain the model for the epic style during the whole period of the poetical literature of the Greeks.

In endeavouring to form a correct estimate of the poet and his works, it is necessary to make some distinction between the popular minstrel of an age when books are either not known or little used, and the cultivated poet of an age which rejoices in all sorts of libraries, and possesses a special class of literary readers, admits of no doubt. The conditions of the work to be done being different, the work itself cannot possibly be the same. It is quite certain, however, that the great majority of the critics and translators of H. in this country have not been in the least acquainted with this distinction, and is, that they strike an entirely false note, and blow the seraphic trumpet of Milton when they should be content to take a plain shepherd’s pipe in their hands. It is very probable that even modern critics would be actuated by the very noble desire of redeeming the author of two such noble poems as the Iliad and the Odyssey from the vulgar fellowship of wandering minstrels and ballad-mongers; but however high the genius of H. unquestionably soared above the best of the medieval ballads to which the English ear is accustomed, it is quite certain both that the materials out of which his great poems were composed were nothing but such popular ballads and tales as delighted our forefathers before the invention of printing, and that the spirit and tone of the Homeric epics is distinguished from that of the literary epics or epics of culture precisely by those characteristics which distinguish our old ballads from the poems of Wordsworth and Coleridge of modern poets, the one who possessed the greatest relationship to the genuine old minstrel poets was Sir Walter Scott; but even in his poetry, many peculiarities can be pointed out, which mark the literary writer of a later age, as distinguished from the popular singer of a people’s bygones and lusty youth. In order to understand H., therefore, we must look on him as the culmination of the minstrel or ballad poetry, in the shape of the minstrel epics; a grand combination of popular ballad materials and ballad tone, elevated to the highest pitch of which it is capable, with the architectural form and structure of the epos. To the recognition of this true character and disposition of the Homeric epics the present age has been led mainly by the adventurous and suggestive criticism of the celebrated scholar, Frederick Augustus Wolf. This distinguished German, originally a professor in Halle, afterwards in Berlin, published in the year 1755 the prolegomena to a new recension of the text of H., in which he maintained the extreme sceptical view already alluded to, according to which the Iliad is no proper epic poem, but only a collection of the fragments of the Iliad and Paradise Lost are so, but only a skillful combination of popular ballads, originally separate, and of whose separate existence the sharp-eyed critic can now easily adduce satisfactory proof. Now, this theory, commonly called, after its author, the Wolfian theory, and which has found, and still finds, not a few ingenious supporters in Germany, contains an important element of truth, which has too often been summarily rejected, along with the error which it presupposes. It is not credible that poets pervaded by such a wonderful unity of tone and plan as the Iliad, manifestly also inspired by a genius of the highest order, should be resolvable into the mere patchwork of skilful compilers; but it is an important truth, however, that the materials of H.’s poetry were not invented by himself, but taken up from the living traditions of the people to whom he belonged, and that even in the grand unity to which his genius has subjected them, their original popular tone and spirit is preserved in a fashion which characteristically distinguishes them from all epic poetry of the literary ages. There can be no doubt that the merits of Wolf in this regard will soon be as universally recognized in every other country as they have long been in Germany; but, in the meantime, it is to be lamented that of those who have written most largely on the subject, neither Colonel Mure nor Mr Gladstone has been able to exhibit to English readers the true golden mean in this matter between the extravagance of the ultra-Wolphins, and the falsity of the anti-Wolphin critics and translators. Among the Germans, Weicker, Nitsch, and K. O. Miller, it may be believed, the best models of judicious and well-balanced criticism in this slippery domain.

The characteristics of H.’s poetry, as the culmination of ballad poetry and the grand poem the minstrel epics may be expressed in a very few words. In the first place, the materials are essentially national, and if not strictly historical in every detail of decoration, grow, like all ballad poetry,
HOMICIDAL MANIA—HOMILDON.

out of the real life of the people, and rest at least upon an honest historical substratum. In this view, the Iliad is as valuable for the earliest history of the Hellenic race, as Herodotus and Thucydides are for the later periods. But it is not for the Greeks alone that H. possesses an important historical value; he is for all ages an important record of the earliest stages of human society, second only to the books of Moses, and perhaps some of the very oldest of the Vedas. The first poems of almost all other arts and sciences afterwards cultivated by the Greeks and Romans are to be found in Homer. In this view, he was to the Greeks themselves an encyclopedia of their national culture; and, as such, to speak, granted only for the polytheistic faith, he is also constantly quoted by their great writers with all the deference due to a Bible.

The poems of H., as a great human inheritance, have naturally been incorporated, by translation, into those who sought in Europe. In Italian, the translations of Cesareo and Monti—in French, that of Montbel—in German, that of Voss, are the most famous. In England, we have tried this great problem in the most various styles, and have given a number of them success in certain partial aspects. The whole excellences of H. have not yet been exhibited in any one of the notable English translations, nor is such a combination perhaps possible. The grand flow, rapid march, and somnous fulness of the original, are well given by Pope; the rough dramatic vigour of individual phrases and passages are best rendered by Chapman; while the unaffected truthfulness, and easy, unpretending grace, which so prominently mark the great Sinyrnnean minstrel, appear most clearly in Cowper. Of the recent attempts which have been made, and are making to present H. in some new aspect to English readers, it is premature to work on H. by Mr. Gladstone: the article "Homer" in Dr. Smith's Dictionary of Ancient Biography; and the article "Homer" in the Encyclopaedia Britannica.

HOMICIDAL MANIA. This is the mononostic mneurice of the French. There is developed, under certain morbid conditions, a blind, irresistible tendency to destroy life. It is independent of hatred, or any appreciable incentive; and even acts in opposition to the general disposition, the interests, and the affections of the perpetrator. Dr. Otto of Copenhagen has recorded a series of motiveless murders. George gives the case of M. N., who was silent and solitary, but reasonable, and confessed a desire to shed blood, and particularly that of his mother and sister by poison. He depicted the dreadful tendency, for he loved them both tenderly. Yet the fit returned, and he cried out: 'Mother, save thyself, or I will cut thy throat!' The victim selected is most frequently a child, a wife, a benefactor, or an object of respect. Homicide is rare in Germany; Esquirol, Marc, Fontville, in France; and Conolly, in Britain, have all demonstrated, and in criminal courts have testified to the existence of this form of mental disease, and ground of irresponsibility; but no recognition has been obtained of the irresistible motiveless homicidal tendency as a bar to trial or to punishment. The impulse, however, is manifested in a more complicated form. It may originate in delusions; and the act which first reveals the mental condition may be committed in supposed self-defense, or to secure the salvation, or prevent the suffering of the individual destroyed. Such manifestation may constitute the characteristic symptom of the disease. Within them every maniac sacrifices all around, or all who resist his course, under the instigation of the predominating passion, or of melancholia and despondency. There are, of course, other less certain diseases which becomes epidemic or imperative. There is in many natures an ill-defined satisfaction on hearing of slaughter, wars, and atrocities; and such details, or the sight of blood, are said to be suggestive of this tendency. Marc states that six cases of insania followed immediately upon the publication of the trial and history of Henriette Cornier, who cut off the head of her saïd. The peculiar condition, various hereditary tendencies, powerful moral impressions, and atmospheric influences, are conceived to induce this tendency. The proximate cause is generally found to consist in marked organic changes in the nervous system, such as are detectable in epilepsy; or in the mental or physical alterations which are supposed to accompany perverted and depraved instincts; although homicidal mania may occur independently of either of these pathological conditions.

Esquirol, Des Maladies Mentales, t. ii. p. 115; Marc, De la Folie, &c., t. ii. p. 24; Yellowles, Homicidal Mania, Edinburgh Medical Journal, August 1862.

HOMICIDE, a term used in English Law to denote the mere killing of a human being without implying the attendant criminal responsibility. It is used with the word justifiable to denote that the killing was done under lawful authority, as hanging a man or killing a prisoner to prevent him escaping, or killing one to prevent an atrocious crime being committed. Excessive homicide means killing in self-defence, or in defence of a wife, child, parent, or servant, or property, or by mere accident. Felonious homicide includes murder of one's self or of another; and manslaughter is killing without malice, but attended with negligence, or hot blood, or without any reason. In Scots law excessive homicide is generally called culpable homicide.

HOMILDON, BATTLE OF. In the autumn of 1402, a Scottish army of about ten thousand men invaded England, under the command of Sir Murdach Stewart of Kincleren, the eldest son of the Regent Albany, and of Archibald Earl of Douglas. They advanced to the gates of Newcastle without opposition, and were returning to Scotland laden with spoil, when they were encountered by an English force under the Earl of Northumberland, his son Hotspur, and the exiled Earl of March or Dunbar. The Scotch took up their position on Homilton Hill, near Wooler. On the 14th September, Hotspur was advancing to charge them, when he was stopped by the Earl of March, until the English archers should do their work. Their shafts were loaded with such effect that, in the words of a contemporary chronicler, they bristled in the dense ranks of the Scottish army like quills upon a hedgehog. At length a gallant knight, Sir John Swinton, cried out to his men that he would show them how to vanquish him. He bewitched you that he stand there to be shot like deer in a park, instead of proving your courage, as of old, by meeting your foemen hand to hand! Let those who will, rush down with me, in the Lord's name and mine, while we retain our lives or fall with honour.' At these words, Adam of Gordon, who was at mortal feud with Swinton, sprang forward, and throwing himself on his knees.
HOMILETICS—HOMINE REPLEGIANDO.

besought the honour of knighthood from the warrior, whom he must now look upon as the best knight in Britain. His request was granted; and the two knights, followed by about a hundred retainers, rushed upon the English ranks. They were slain to a man, but not before they had made such slaughter, that the English captains were said to have confessed, that if all the Scots had fought as well, the day would have had a different issue. As it was, the English had an easy victory, and the Scots were utterly routed. Many of their leaders were taken prisoners; fire of their best knights, with many of their bravest esquires, were slain; and besides the numbers that were killed on the field by the English arrows, about five hundred were drowned in attempting to cross the Tweed.

HOMILETICS, that particular branch of sacred rhetoric which regards the composition of the familiar discourses known under the name of homilies. The earliest writer on the subject of homiletics is St Augustine, whose book, De Doctrina Christiana, contains a form of the prolate rhetoric to sacred uses. Isidore Manius and Isidore of Seville also incidentally treat the subject; but the nearest approach to a systematic treatment of the subject in medieval literature is found in Marheineke's work Homiliae Conciones Pastorales. St Carlo Borromeo's Instruzioni Pastorali was a part of his general scheme for the improvement of clerical education; and in the eclesiastical course, as well of Catholics as of Protestants, homilies occupies an important place. The bare enumeration of the works of Schott, Marheinecke, Themenin, Sailer, Gisbert, Brand, Labenz, may shew the importance which is attached in both churches to this branch of sacred science.

HOMILLARIUM, a collection of homilies for the use of pastors. Such collections were in use from a very early period. Mabillon mentions a very ancient Gallican homiliarium (De Lit. Gallican.). The fifty homilies of Venerable Bede, too, were in familiar use among the clergy in all parts of the West, and we find in the letters of the early medieval time, traces of a busy interchange of homilies, original or otherwise, between bishops and clerical houses in distant countries. The style, however, was imperfect and scanty, and one of the many reformatory measures of Charlemagne was a compilation of homilies under the title of homiliarium, which was made under his direction by the deacon Paul Warnfried. It was compiled in the end of the 8th c., and contains homilies for all the Sundays and festivals of the year. Many synods of that and subsequent periods directed the clergy to translate these sermons for their flocks, and the collection continued in use for this purpose down to the 16th century. It was printed at Speyer in 1482, and again at Cologne in 1557. A collection of homilies is also ascribed to Alcuin, but it seems more likely to have been but a modification of the homiliarium of Warnfried. A collection of English homilies turned into verse, that they might be more readily remembered by the people, appears to have been composed about the middle of the 13th century, by John Lowthorp, De Homiliis Monarchicis for every Sunday and festival-day in the year, exists in MS.; and a portion of it has recently been edited by Mr Smale, librarian to the university of Edinburgh.

HOMILIES OF THE CHURCH OF ENGLAND, in a collection of sermons, the first part of which was published in 1547, the first year of the reign of Edward VI., to be read in the churches, partly in order to supply the defect of sermons, partly, also, to secure uniformity of doctrine, and to guard against the heterodoxies, old and new, which at that time threatened the unconsolidated church. The second part was published in 1562, at the same time with the articles, under Elizabeth. The 35th article declares that 'the Book of Homilies doth contain a godly and wholesome doctrine, and necessary for these times.' The titles are enumerated in the article, and are twenty-one in number. The homilies are not now read in churches; but there is no law to prevent their being so read, and they are frequently appealed to in controversies as to the doctrine of the Anglican Church on the points of which they treat. The precise degree of authority due to them is matter of doubt.

HOMILY (Gr. homilia, converse) primitively signifies a discourse held with one or more individuals, but in ecclesiastical use it means a discourse held in the church, and addressed by the minister to the congregation. The practice of explaining in a popular form the lessons of Scripture read in the synagogues, had prevailed among the Jews, and seems to have been adopted in the Christian churches from the earliest times. The discourses employed for this purpose were of the most simple character; but with the exception of the discourses to be found in the Apocrypha we have here no sample of this form of composition earlier than the homilies of Origen in the 3d century. Taking these as a type, the early Christian homily may be described as a popular exposition of a portion of Scripture, accompanied by moral reflections and exhortations. It differs from the sermon (Gr. logos, Lat. oratio) in eschewing all oratorial display, and in following the order of the scriptural text or narrative, instead of being thrown into the form of a rhetorical discourse or a didactic essay. The schools of Alexandria and Antioch appear to have been the great centres of this class of sacred literature, and in the early centuries we find the names of Hippolytus, Metrodorus, Clement of Alexandria, Irenaeus, and Gregory Thaumasus, as principally distinguished. But it was in the following centuries that the homily received its full development in the hands of the Oriental Fathers, Athanasius, the two Gregorys, of Nyssa and of Nazianzus, Basil, the two Cyles, Leo and of Alexandria, and above all, Chrysostom; and in the West, of Ambrose, Augustine, Peter Chrysologus, Leo, and Gregory the Great. In later centuries, Venerable Bede, the popes Sylvester, Leo II. and III., Adrian L., and the Spanish bishops, Isidore of Seville, and Idefonse, continued to use the homiletic form; and even in the modern church, many preachers have regarded it as the best medium of scriptural instruction; and two different forms of homily are distinguished, the higher and the lower. The former follows the order of matter, rather than of any scriptural passages assumed to be expanded; the latter is a purely expository and moral exposition of some lesson from the liturgy, or of some other extract from Holy Scripture. It is right to add, however, that this strictly historical acceptation of the name homily is by no means uniformly preserved in modern use, as the name homily is very frequently used, almost as a synonym for sermon, and signifies nothing more than a plain, moral discourse, without ornament or rhetorical pretensions, but with no pretension of being moulded upon the ancient patristical model.

HOMINE REPLEGIANDO, an old writ in English law, meaning to bail a man out of prison; now disused.
HOMEOPATHY.

HOMEOPATHY, from two Greek words signifying ‘similar suffering,’ is a system of medicine introduced into practice about the close of last century by one of the most radical physicians of the name of Hahnemann (q.v.). It is founded upon the belief, that medicines have the power of curing morbid conditions similar to those which they have the power to excite; expressed in Latin by the phrase, similia similibus curantur, and in English by ‘Like cures like.’ That diseases are cured by substances which produce in persons in health symptoms like those presented by a patient, has been from the earliest times a recognised fact, both by medical writers and by poets who have expressed the prevailing belief of the ages in which they lived. Among the former, we find the author of a treatise generally ascribed to Hippocrates, entitled On the Places in Man. This writer gives numerous examples of what may be called homeopathic cures; and recommends for the cure of mania this remarkable prescription: ‘Give the patient a draught made from the root of mandrake, in a smaller dose than sufficient to induce mania.’ The works of the poet illustrate this belief. Probably the oldest expression of it is in some lines ascribed to Athenaus and Antiphanes, who lived 404 B.C., which have been thus translated—

‘Take the hair, it is well written,
Of the dog by which you’re bitten;
Work off one wine by his brother,
And one labour with another;—
Cook with cook, and strive with strife,
Business with business, and wife with wife.’

Shakespeare, in Romeo and Juliet, thus expresses the same maxim—

‘Tut, man! one fire burns out another’s burning:
One pain is lessened by another’s anguish.

Take thou some new infection to the eye,
And the rank poison of the old will die.’

Milton, in the preface to Samson Agonistes, gives his version thus:—‘In physic, things of melancholy hue and quality are used against melancholy, sour against sour, salt to remove salt humour’s;’ &c. Thus, there has always been a resemblance of medicines, sometimes cured diseases similar to those they caused. But it was reserved for Hahnemann to propound the startling dogma, not only that medicines did occasionally produce such cures, but that true disease of the body is a condition which can only be effected by recognising this principle as the guide for the selection of the right remedy in any given morbid condition of the system. The great difficulty of applying this rule to practice arose from the absence of accurate information of the action of medicinal substances upon persons in health, and Hahnemann had to institute a series of experiments upon himself and others, in order to ascertain the effects of the drugs he proposed to employ. He engaged his friends and disciples in this task; and they took given quantities of the substance which was the subject of experiment, and each kept a record of the effects produced. The various records thus obtained were submitted to Hahnemann, who compared them together, and with his own observations on himself, and out of the results thus obtained, compiled what goes by the name of 'a proving' of the medicine. Hahnemann lays it down as one of the fundamental propositions of homeopathy, that no medicine should be given to the sick which has not first been proved upon those in health. He devoted himself to this task, and has left ten volumes of such 'proving's; out of this work the various abridgments in popular use in this and other countries have been derived. The design of proving a medicine is to ascertain, with the utmost possible accuracy, all the properties of the substance in question; for example, you ask what effect, then it becomes possible to administer it in accordance with the principles of homeopathy. To do so, however, it requires that the medicine should be given by itself. Thus, the second proposition of Hahnemann’s system is, that whatever medicine only one medicine should ever be given at once.

To ascertain the effects of medicinal substances upon persons in health—from the knowledge thus obtained to select a remedy whose action corresponds with the symptoms of the patient under treatment—to give this remedy by itself alone, are three of the fundamental rules for the practice of homeopathy. The fourth is, that the dose of a homeopathic medicine should be so small as not to cause general disturbance of the system, its action being limited to that portion of the body which is in a morbid condition. How small that is, can be ascertained only by experiment. When Hahnemann propounded his system, he pointed out that the following should be the belief of the medical profession:—The dose of medicines depends upon two conditions: first, the mechanical form in which it is administered; and second, the state of the body of the person who takes it. An ounce of belladonna, or a hard pill of belladonna, or fire-grains, swallowed by a robust and healthy man, may be followed by only trifling symptoms; but let that be dissolved in a pound of water, and an ounce of the solution be given every hour, then we shall have some of the symptoms of the poisonous action of the drug. But if, instead of administering it to a person in rude health, it be given to one who is suffering from such an inflammation of the tumours as belladonna produces, then we shall find that the indica-ments will be most acted on by a grain of the poison in a specific irritant. Disease implies a preternatural sensitiveness. An inflamed eye cannot bear light, an inflamed stomach cannot bear food, and every diseased organ is powerfully affected by the particular substance which has, in consequence of a surgical operation, a close affinity with the character of the morbid condition in which it is at the time its specific medicine is administered.

To the belief of which it was desirable to reduce the dose, a series of experiments were necessary. It was a matter to which all à priori reasoning was inapplicable. In an article published in Hufeland's Journal in the year 1801, Hahnemann gives an account of the first time he employed a grain of belladonna can have the word eos is apt to lead to misconceptions. Let us ask Nature what effect of a grain of belladonna has? Then states the conditions of the experiment—viz., that this fraction of a grain should be administered to a patient suffering from a peculiar form of scarlet fever then prevalent in Germany, and presenting a combination of symptoms bearing a close resemblance to those produced by belladonna. Hahnemann maintained that this fraction of a grain was sufficient for the purposes of homoeopathic cure. Finding so minute a quantity efficient, he carried the diminution still further, and introduced a whole novel system of medical knowledge, which came to be known as homoeopathy.

Homeopathic doses are all expressed by fractions, thus: Suppose the medicine to be a vegetable substance; a strong tincture is made of it, and this is technically called the mother tincture. One drop of this mother tincture is added to 99 drops of alcohol, so as to dilute it 100 times, and this preparation is called the first dilution, and marked 1. Again, a drop of number 1—that is, of the 1/10th of a drop of the mother tincture—is mixed with other 99 drops of alcohol, and marked 2, or the second dilution.
HOMEOPATHY.

This contains the 1/12th of a drop of the mother tincture, or 1/546,000 of a drop of the mother tincture. This simple process of subdivision is continued, and each step is recorded in the same way; thus, number 3 means a millionth; number 6, a billionth; and number 30 (which is the highest recommended by Hahnemann), a decillionth. Insoluble substances, of course, cannot be thus diluted; they are triturated with sugar of milk. One grain, say, of sulphur is triturated with 99 grains of sugar of milk, forming the first triturations, and marked number 1; a grain of this first triturations is then triturated with 99 grains of sugar of milk, and this makes the second triturations. The third and subsequent are made in the same way; but after advancing to the fifth or sixth, then it is presumed that all substances become soluble in this very minute proportion in alcohol, and alcoholic dilutions are made of them in the same way as of the vegetable tinctures. After making these alcoholic preparations, the homeopathic chemist saturates with them minute particles of sugar of milk, known technically by the name of globules or pilules.

A system so revolutionary naturally encountered most determined opposition. In Germany, there were legal obstacles to its practice. In Austria, physicians were forbidden to obtain, possess, or administer their own medicines, even gratuitously; all medicines administered to the sick were prepared by the apothecaries. Thus, without some change in the law, it was practically impossible to carry out the homeopathic method of practice, for the apothecaries were naturally so opposed to a system which involved the utter annihilation of their profitable occupation, that it would have put their self-employment and success at such a face to have committed the fate of homeopathy in the country. This happened that, from the year 1818 to the year 1836, homeopathy was forbidden to be practised in Austria, and only tolerated under exceptional circumstances, as, for example, in a small hospital attached to an establishment of the Sisters of Mercy, and under powerful patronage. In 1836, cholera broke out for the second time in Vienna, and Dr Fleischmann, the physician to this institution, had previously been appointed to the chief hospital for the reception of cholera patients. He undertook the charge, on the condition that he was to be allowed to employ homeopathy in their treatment. This was granted, homeopathy having hitherto been regarded by many as a mere metaphysical abstraction, and there were no preparations in Germany in cholera in 1830–1831. He treated 732 cases; of these, 488 recovered, and 244 died. The hospital was under daily inspection by the government, and the result of the treatment was made known to Count Kolonrat, the home-minister. Shortly after, the emperor issued an ordinance granting to every duly qualified physician the right of practising homeopathy. The cholera mortality under homeopathic treatment was in this instance one in three, while the average mortality of the same epidemic at the same place was two in three. —Wilde's Austria.

When cholera was approaching Western Europe, Hahnemann's pupil, Dr Leopoldo Tronzo, who had been 'provings' to ascertain what substance resembled most nearly in its effects the symptoms of the disease. The medicine he found to be camphor; and before he had ever seen a case of cholera, guided by the details given by practitioners, he announced in the year 1821: 'Every one, the instant any of his friends is taken ill of cholera, must immediately give him camphor.' This bold prediction, that camphor was the antidote for the disease that had devastated Hungary and Moravia, and camphor has since been accepted universally by homeopathists as the most efficient remedy against an invasion of cholera. During the late Crimean war, it was extensively employed in the French army, by the special desire of the emperor.

The reported success of the homeopathic treatment of cholera at Vienna had a powerful influence in directing public attention to the hospital where the new system was practised. The attention from all parts of Europe and from America went thither to watch the treatment. In a Report published by Dr Fleischmann some years ago, it is stated that at that time he had treated 17,313 cases, chiefly of acute diseases. Among these were —of erysipelas, 514 cases, of which 510 recovered; of rheumatic fever, 1417, of which 1416 recovered; of intermittent fever, 1666, of which 1658 recovered; of inflammation of the lungs, 1629, of which 1604 recovered.

From Germany as a centre, where it is now extensively practised and taught, homeopathy spread over Europe and America. In America there are upwards of 300 thousand avowed practitioners of the system. In France, Italy, Spain, and other countries, it has numerous adherents, many of whom occupy influential positions of trust and authority. It was introduced into England in a more or less disguised form by the year 1827, by Dr Quinshill; and there are now about 300 registered practitioners in Britain who have adopted it. In London, there is a hospital capable of containing upwards of 100 patients, where lectures are regularly delivered by appointed teachers.

The objections entertained by physicians to the so-called 'homeopathic' practice of medicine are based, not upon any unwillingness to employ medicines whose action resembles the more or less characteristic features of the disease for which they are prescribed, but solely on the impossibility, according to the common view, of adopting this as a specific rule of practice, and especially as an exclusive and all-embracing law of therapeutics. The action of emetics in some kinds of indigestion, and of rhubarb in some kinds of diarrhoea, are familiar examples in daily use, showing that ordinary practice is not regulated by any kind of rule corresponding to what is called the homeopathic law of 'similia similibus curantur.' But in these cases the physician does not in the least commit himself either in favour of or against the law, but rather sets it aside, as having nothing to do with the real principle of the cure, which is to be found in common sense and experience, applied to the facts of individual cases and groups of cases. The true physician is not a sectary; he disowns all artificial formulas of cure, exactly as he disowns homeopathy; and he especially disowns the nickname of allopasthis, invented for him by Hahnemann. His belief in remedies is not founded on extreme generalisations, and he refuses to be limited in his practice by any other technical rules than those derived from a fair view of facts investigated on the ordinary principles of positive science. It is very certain that Hahnemann's alleged 'provings' have been projected as in great part visionary by the great majority of those who have attempted to ascertain personally the effect of the same remedies; and it is equally certain that Hahnemann himself admits the general aggravation of diseases by homeopathic doses when administered in sensible quantities, and that the system of infinitesimal doses was with him simply a last refuge from the contradictory character of the results obtained under the earlier trials of remedies devised according to his assumed principle. The argument of physicians in general
HOMOGANGLIATA—HONDURAS.

has been, that the principle was false, and that the infinitesimal doses are its reductio ad absurdum. They admit freely that homoeopathy has in some instances, produced, by ill-fortune, the spontaneous recovery of disease, and correcting a blind faith in heroic remedies; but although individual cures of some local credit have here and there been made, there is not the slightest appearance of a movement in the profession towards adopting homoeopathy as a system, and its much-vaunted statistics are generally regarded as extremely fallacious.

HOMOGANGLIATA (Gr. homo, the same, and ganglion, a ganglion), the name given by Owen to the Articulata of Cuvier, in accordance with a belief in the great importance of the nervous system as a basis of zoological classification. Each segment in the lowest H. contains a pair of ganglia with nerves proceeding from them; all, however, communicating by nervous filaments, and constituting a continuous chain. In the higher forms, there is a greater concentration, and a more evident allotment of the ganglia of particular segments to particular functions.

HOMOLOGATION, a Scotch law-term, denoting an act or conduct which confirms or approves of something which otherwise might be invalid. Thus, an informal deed, though useless in itself, yet, if acted on by one or both parties, will be set up and made valid, as against the party not homologating. To constitute homologation, a clear knowledge of what the party is doing is necessary. The term is not used in English law, but similar effects are produced, and bear other names, such as confirmation, retrenchment, and ratification.

HOMOLOGOUS quantities or magnitudes in Geometry are such as correspond, or are like to one another. For example, in similar triangles, the homologous sides are those which are opposite to corresponding angles. In the triangles ABC, A'B'C', which are similar, BC is homologous to BC', AB to AB', and AC to AC. See Homology.

HOMOLOGY, in Anatomy, is the term now used to indicate structural correspondence, while the term analogy is employed to indicate functional resemblance. Thus, by homologue, is implied 'the same name in different animals, and in every variety of form and function'; while by analogue we understand 'a part or organ in one animal which has the same functions as another part or organ in a different animal.' For example, the wings of an insect are the analogues of those of a bat or bird, but not the homologues; whilst the latter are homologues with the arms of man, the fore-legs of quadrupeds, and the pectoral fins of fishes. For further illustration, see Owen On the Archetype and Homologies of the Skeleton.

HOMOOUISIAN (Gr. homoos, the same, and ouios, substance), and HOMOIOUSIAN (Gr. homoios, like, and ouios, substance), two terms that long distracted the primitive church. The first was the shibboleth of orthodoxy in the Arian controversy, the decree of the council of Nice, which declared the Son to be homoeousian, of the same substance with the Father. The rigid Arians, who resisted the decree of Nice, of course rejected the term. The semi-Arians, who held the subordination of the Son to the Father, were divided as to its use. Some of them rejected the word altogether, as directly conveying a false idea; others, while they did not absolutely reject the idea, regarded the word as objectionable, but rather as susceptible of misinterpretation, than as absolutely false. Both parties argued against its use from a decree of the council held at Antioch in the year 265 against Paul of Samosata, in which the name homoeousian, as applied to the Son, was expressly condemned. They contended, therefore, that the Fathers of Nice had erred in applying it, and they proposed to substitute for it the term homousian (of a like, but not identical substance with the Father). Without entering into the doctrinal controversy, it will suffice to say, that the term, as used by the council of Antioch, bore a very different signification from that which the Fathers of Nice attached to it. In the controversy with Paul of Samosata, who, with the Sabellians, held that the Father and the Son have but one and the same person, the term homousian was employed to signify personality. Hence, when the council condemned the doctrine of Paul, that the Son is homoeousian with the Father, it merely declared that the Father and the Son are not one and the same person. On the contrary, the council of Nice, in defining that the Father and Son are homoeousian, understand ousia in the very different signification of substance or nature. See the historical treatises of Athanasius, Newman's translation.

HOMOPTERA (Gr. homoos, the same, uniform, pteron, a wing), according to some entomologists, an order of insects; according to others, one of the two great divisions of the order Hemiptera (q. v.), differing from the Heteroptera in having the hind pair of wings completely divided into two wings; therefore, not membranous, but leathery, and so passing into the conosternum, or sucker originating from the inner part of the head near the thorax, or even between the first pair of legs. The H. feel on the juice attached to plants, and some of them are very troublesome to farmers and gardeners. The females of many have an ovipositor, by means of which they pierce plants, in order to make a place for the reception of their eggs. The larva is active, and resembles the perfect insect, but are wingless. The pupae are also active, and have rudimentary wings. Among the H. are Cicadas, the largest of the order, Lantern-flies, Flower-flies, Aplides, and the Coccon tribe.

HONAN, the chief of the central provinces of China, having an area of 65,104 square miles, and a population of 23,837,171. Its capital, Kaifung-fu, is situated on the Yellow River, from which it has often suffered, the river-bed being here elevated above the level of the country. It has been overflowed 26 times. In the reign of Tui (2832 a. c.), it was the capital of China. It has suffered various vicissitudes. In the 12th c. of our era, it was six leagues in circumference. At present, the city is uninteresting to Europeans, save as the residence of the Jews of China, now dwindled to a few families.

HONAWA'R, a seaport on the Malabar or west coast of the peninsula of Hindustan, belongs to the presidency of Madras, which here extends from shore to shore. It is in lat. 14° 17' N., and long. 74° 30' E., being 240 miles to the south-east of Bombay. It stands on the north side of an inlet of the Arabian Sea, which receives the Gersepa or Shervatti; from the Western Ghauts. Though both the harbour and the anchorage outside have a good bottom and a sufficient depth, yet, in the season of the south-west monsoon, the surf is a serious impediment to navigation.

HONDURAS, the middle state of Central America, extending east and west from the Caribbean Sea to the Pacific Ocean, and separating Nicaragua on the south-east from Guatemala on the
HONDURAS—HONEY.

north-west. It stretches in N. lat. between 13°10' and 16°40', and in W. long. between 88° and 89° 46', containing about 42,000 square miles, including a portion of the Mosquito Territory, and 358,000 inhabitants, most of them, wholly or partly, of aboriginal blood. The country is generally moun-
tainous, being traversed by the Cordillera de la Sierra, which connect the Andes on the south with the Sierra Madre on the north. The principal rivers are the Chameleon, Ula, Aguan, and Choluteca.

An excellent agricultural country, H. abounds also in mineral wealth. The minerals are gold, silver, copper, iron, cinnabar, zinc, antimony, tin, platinum, opal, amethysts, asbestos, chalk, limestone, marble, and coal. The soil produces valuable timber, fruit-
trees, cotton, sugar, coffee, tobacco, indigo, maize, wheat, potatoes, yams, plantains, bananas, and beans. The foreign trade is carried on chiefly with Great Britain, the United States, and Spain. The imports, amounting in 1855 to 675,000 dollars; or £355,000 sterling, consisted to the extent of more than one-half of cotton manufactures—the articles next in order, woollens, silks, and wines and spirits, having been almost precisely one-fifth part of the sum-total. To distinguish the northern and southern branches of commerce among the internal commerce and that with reference to the year already mentioned—the official returns stood thus:

The single outlet on the latter side is Amapoli; while on the former are Omoa, Truxillo, and Puerto Cabellos.

HONDURAS, BAY OF, an inlet of the Caribbean Sea, extends between Yucatan and Guatemala on the west, and Honduras on the south. From the adjacent countries of British Honduras and Yucatan it receives a variety of streams, the chief of which is the Balse, and contains several islands. The shore is marked by reefs.

HONDURAS, BRITISH. See BALIZE.

HONES, or WHET-STONES, a particular class of stones used for the purpose of sharpening edge-tools, such as knives, scythes, &c. They are usually cut into pieces about a foot in length, and from an inch to two inches thick, and either left square or rounded, according to their intended uses. The finest kind of hone is that called oil-stone; these are hard, compact, and so very silicious, that they readily wear down the hardest steel; they are varieties of slate, derived from the argillaceous slates of the Palæozoic period. The best are those brought from Turkey; Bohemia is also celebrated for its hone; and excellent ones are found in Persia, in the Harz Mountains, in Styria, in America, Spain, Peru, and in Siberia. In Great Britain, several localities yield stone-stones of excellent quality, and none better than the celebrated Water-of-Ayr stone, which is much used for polishing copper-plate and other types for hones. The Welsh oil-stone or Idwall stone, and the cutler's green-stone, are obtained from Snowdon in Wales; and in the neighbourhood of Tavistock, the Devonshire oil-stones are procured. Whatever part of the world they come from, they resemble each other very closely. The hones used for sharpening scythes and other large blades are usually made of some coarse-grained sandstone; these are manufactured in many localities.

HONESDALE, a new and flourishing village in the centre of the United States America, 160 miles north-east from Harrisburg. It is situated at the confluence of the Lackawaxen and Dvberry Creeks, and connected by canal and railway with New York. It is the centre of an important coal-mining district, from which anthracite coal is sent to the Atlantic cities. In 1859, it contained nine churches, an academy, bank, foundry, tanneries, glass-works, mills, and three newspapers. Pop. about 5000, and rapidly increasing.

HONESTY (Lunaria), a genus of plants of the natural order Crucifera, of which two species, natives of the south of Europe, L. corniculata, and L. reddeira, have long been cultivated in British flower-gardens, partly on account of the beauty of their flowers, and partly of the curious appearance of their large flat seed-pouches (silene or). They are 1—2 feet high, with rather coarse foliage. The origin of the English name is doubtful. Some of the older English poets mention the plant as Lunaria. It was regarded, in the days of superstition, as possessing extraordinary virtues.

HONEY is secreted by the nectariferous glands of flowers, from whence it is collected by the working or neuter bees, which extract it by means of the proboscis, and pass it into the dilatation of the cephalus, known as the crop or honey-bag. When the animal has arrived at the hive, it disgorges the honey, probably altered by an additional secretion of the crop, into the cells of the comb. It is used by the bees as food, but it is its general properties and its uses to man that here require notice.

The composition of honey varies somewhat according to the food of the bees, their age, the season, &c. Hybula, a mountain in Sicily, and Hymettus, a mountain in Attica, were in ancient times celebrated for the honey, though the consequence of the wild thyme and other fragrant herbs growing on them. The honey of Narbone and Channouni is now held in high estimation for similar reasons; and in this country, honey obtained by bees having access to heather has, as is well known, a peculiarly agreeable taste. The substances which have been recognised in honey are sugar of two kinds—one crystallisable and analogous to Glucose (q.v.), and the other uncrystallisable, mannite (according to Guibourt) a gummy, wary, colouring and odorous matters; and pollen. The proportion of crystallisable sugar increases with the age of the honey, so as to give it time a granular character. The best honey is a clear fluid contained in a white comb, while older honey is of a yellowish, and even reddish tint.

From the remotest times, honey has been employed as an article of food; and to the ancients, who were unacquainted with sugar, it was of more importance than it now is. ’A land flowing with milk and honey’ offered the highest conceivable advantages to the eastern mind. Taken in moderate quantity, honey is nutritive and laxative, but dyspeptic persons often find that it aggravates their symptoms. Its therapeutic action is probably not very great, but it is employed with advantage to flavour and give a demulcent character to various drinks or mixtures prescribed for allaying cough; and in the form of ozened, which is usually prepared by mixing honey, acetic acid, and water, it is frequently added to gargles, or mixed with barley-water, so as to form an agreeable cooling drink in febrile and inflammatory affections, or given as an expectorant in coughs and colds.

It should be mentioned that honey occasionally possesses very deleterious properties. Xenophon, in his history of the Retreat of the Ten Thousand (Anabasis, book iv.), describes the honey of Trebizond as having produced the effect of temporary madness, or rather drunkenness on the whole army who ate of it. Mr Abbot, writing from Trebizond in 1833
HONEY BUZZARD—HONEY-DEW.

to the secretary of the Zoological Society, observes that he has himself witnessed that the effects of this honey are still precisely the same as those which Xenophon describes, and he adopts the views propounded by Tournefort in 1704, that the poisonous properties are consequent on the bees extracting the honey from the Apis Dominica. Many other instances of poisonous honey are on record.

Honey, although not of so much importance commercially as it was before sugar became so large an importation, is nevertheless brought to this country from abroad in considerable quantities, which, in addition to the home produce, mentioned in the article Bee, shows that it is still largely in demand. Nearly fifty tons are annually imported from various parts of the world: North America, the West Indies, Portugal, France, and Greece, are the countries from which we receive most. The French is very fine, and is chiefly consumed for domestic and medicinal purposes; the Greek is the finest, and is only used as a table delicacy; most of the other kinds are inferior, and excepting some portion which is used by the tobacco manufacturers, to give a spurious sweetness to tobacco, it is difficult to account for the consumption of so large a quantity. Honey is often very much adulterated. One of the most common materials used for that purpose is flour; samples of French honey have also been found largely adulterated with gelatine; the latter cannot so easily be detected, as there is always present naturally a portion of gelatine in honey. The quality of even the best depends upon its careful refinement or clarifying. If honey be slightly heated, the chief impurities rise to the surface, and can easily be removed by skimming; this is usually done, except in the case of virgin honey, which is generally sufficiently pure for most purposes.

HONEY BUZZARD, or PERN (Pernis), a genus of Falconidae, allied to kites and buzzards, but differing from them, and from all other Falconidae, deposit their eggs; and the larvae feed on the honeycomb, through which they make tunnels lined with silk, and in the midst of which they finally spin their cocoons and undergo their transformation. The cocoons are often united in little heaps. These moths, when numerous, are very injurious, and sometimes quite destructive to the bees, from the stings of which they seem to enjoy a perfect immunity.

Honey Buzzard (Pernis apivorus).

in having the lore, or space between the eye and the bill, closely covered with feathers, which overlap one another like scales. The food of honey buzzards consists, not of honey, but chiefly of bees, wasps, and their young, in quest of which these birds dig up the ground, to get at the nests of the insects. They feed also partly on other insects, and less frequently on lizards, small birds, &c. One species (P. apivora) is found in Britain, but is rare; it is rather larger than a common buzzard.

HONEYCOMB MOTH, or WAX MOTH (Galleria), a genus of small moths of the same tribe with clothes' moths, of which some of the species are remarkable for infesting bee-hives. There they

Honeycomb Moth: a, Galleria mellonella; b, larva; c, pupa; d, larva working its way through honeycomb; e, Galleria silvina.

G. mellonella or cereana, perhaps the most destructive species, is about an inch in extent of wings; G. silvina is not much more than half an inch. Both have a satiny appearance, and are amongst the worst enemies the bee-keeper has to encounter.

HONEYCOMBS, in guns, are flaws resembling the cells made by bees, worked in the metal by the action of exploded gunpowder. They spread rapidly, and, with continuous firing, soon eat into the metal to such an extent as to render the further use of the gun dangerous.

HONEY-DEW, a viscid saccharine exudation which is often found in warm dry weather on the leaves and stems of plants, occurring both on trees and herbaceous plants. It is usually, but not always associated with the presence of Aphides, Coex, and other insect species which feed on the juices of plants, and its flow is ascribed to their punctures; but the rupture of the tissues from any other cause, such as the state of the weather, seems also to produce it, and warm dry weather seems to be necessary for the production in the sap of that superabundance of sugar which is thus thrown off. Aphides themselves exude by certain peculiar organs (see APHIS) drops of a fluid which is called honey-dew, which probably differs considerably from the direct exudation of the plants on which they feed, but mingles with it where they abound. Honey-dew is often so abundant as to fall in drops from one leaf to another on to the ground, sometimes falling from trees even as a copious shower. Different kinds of manna are the dried honey-dew or saccharine exudation of certain plants. See MANNA. But very generally, this exudation, as it dries, costs the surface of leaves and branches with a clammy film, to which everything brought by the atmosphere adheres, and on which moulds and other small fungi soon grow, and thus the pores of the plant are clogged and its health is impaired. Gardener are therefore careful to wash off honey-dew with the syrup. Orange and lemon plantations sometimes suffer great injury from the abundance of honey-dew; and it has proved a cause of very great loss in the coffee-plantations of Ceylon.
HONEY-EATER—HONEY-SUCKLE

HONEY-EATER, or HONEY-SUCKER, a name sometimes given to some of the Sun-birds (q.v.), but also the common name of a large family of birds nearly allied to these and to humming-birds, and peculiar to Australia and the islands of that part of the world. This family, Meliphagidae—of the order Passeres, and tribe Meliphagidae—has a long curved sharp bill, not so slender as in humming-birds and sun-birds; the tongue terminates in a pencil of delicate filaments, the better to adapt it for sucking honey from flowers, or juices from fruits. These are a principal part of the food of the honey-eaters, but they also devour insects in great numbers. They are birds of elegant form, and generally of gay plumage. Most of them have a long and broad tail. They may be observed fluttering and darting among trees and shrubs when in blossom, and are very abundant in all parts of Australia. They are extremely vivacious and active, and keep up a continual chattering. One of the most splendid species, Meliphaga or Ptiloria pernuda, is called the Rifleman or Rifle Bird by the Australian colonists. Another species, Myzomela melanops, is called the Bell Bird, because its voice much resembles the tinkling of a little bell. To this family is referred the Poe Bird, Parson Bird, or Tui-tui (Prosthemadera Novae-Zelandiae) of New Zealand, a bird larger than a blackbird, and of a deep metallic green colour, becoming bronze and black in certain lights, with snow-white tufts of downy curling feathers on the sides of the neck. Unlike most of the Meliphagidae, it is a bird of fine song. It has also great powers as a mocking-bird, readily learns to speak many words, and becomes very familiar in domestication.

HONEY-GUIDE, INDICATOR, or MOROC (Indicator), a genus of birds ranked in the Cuckoo family, but differing from the true cuckoos in characters which show an approach to woodpeckers, and also, in some respects, to creepers. They are all natives of Africa, and are found in almost all parts of it. They have acquired their name from guiding men to honey; a curious instinct in the nature of them to flutter near the traveller with frequent repetitions of a cry which resembles the syllable rrrr; and it is said, that if followed, they almost always lead to a place where a bee's nest may be.

HONEY LOCUST TREE (Gleditschia triacanthos)—also known as the Sweet Locust and Black Locust, and in Britain as the Three-thorned Acacia—a lofty and beautiful tree of the natural order Leguminosae, sub-order Cestpliinae, a native of the valleys of the Alleghenians, and of the basin of the Mississippi. It is not found wild on the Atlantic coast of North America, although often planted for ornament in the vicinity of habitations. The flowers—which are small, greenish, and in spikes—have, when perfect, six stamens and one pistil, but are very generally unisexual. The flowers are twice pinnate, without terminal leaflets, the numerous small leaflets giving a peculiar graceful-ness to the foliage, which is of a light shining green. The tree is furnished with numerous sharp triple spines. The pods are long, flat, penulotous, often twisted; the seeds large, brown, and enclosed in a pulp, which, when the pod is ripe, is very sweet. Sugar has been made from it, and when fermented, it yields an intoxicating beverage, in use among the American Indians. The honey locust attains a height of 70 or 80 feet. Trees of large size are to be seen in some parts of Britain. The wood resembles that of the American Locust Tree (q.v.), or False Acacia (Robinia pseudacacia), but is more coarse-grained.

HONEY-STONE, or MELLITE, a mineral of remarkable characters and composition, found in connection with coal and sulphur in several places in Germany. It occurs in square octahedrons, looks like a honey-yellow resin, and may be cut with a knife. It is a mellite of alumina, consisting of mellic acid, alumina, and water.

HONEY-SUCKLE (Lonicera, or, according to some botanists, Caprifolium, which others make a sub-genus of L.), a genus of plants of the natural order Caprifoliaceae. They are shrubs, often twining, and have small white or yellow flowers in pairs. The calyx is short and 5-toothed; the corolla tubular-funnel-shaped, 5-cleft, generally two-lipped; the fruit a 3-celled and many-seeded berry. The Common H., or Woodbine (L. periclymenum), is very abundant in woods and shrubberies in most parts of Britain. On account of its beautiful cream-coloured whorls of flowers and their delicious fragrance, it is often planted in shrubberies, and trained against walls. It is said to be the 'twisted eglantine' of Milton. The phenomena observed in its growth have been adduced in proof of a perceptive power in plants: the branches shooting out till they become unable to bear their own weight; and then, on the next meeting with another branch, twining around it, from right to left; but if they meet only with one another, twining in different directions, one to the right, and another to the left.—Very similar to this is the Persiculate H. (L. caprifolium), with paler whorls of flowers, and remarkable for having the upper leaves united so that an opposite pair form one leaf, through the middle of which the stem passes. This peculiarity is confined to the flower-bearing shoots, and does not occur on the young runners; it is also most perfect nearest the flower. This species is a native of the south of Europe, but now naturalised in many parts of Britain, and much planted, as although less powerfully fragrant than the Common H., it flowers earlier. There are numerous other species, natives of Europe, Siberia, and North America.—The Fly H. (L. xylotoon) is an erect shrub, a native of Europe and Asia, scarcely indigenous in Britain, but common in shrubberies. Its flower-tubes are not unfrequently used in some parts of Europe for tubes of tobacco-pipes; and it is said to make good hedges in dry soils. Other erect species are not unfrequently planted in shrubberies.—The Trumpet H. (L. sempervirens), called in America the Coral H.,
HONEY-SUCKLE—HONOLULU.

is a native of the southern states of North America, often planted in Britain on account of its beautiful flowers, red in the outside, and scarlet within, which, however, have no fragrance. It is a twining ever-green shrub.—The berries of the honeysuckles are nauseous.—The name H. is also given to shrubs very different, from this genus, but of which the flowers are also scarlet, as for species of Discelis, in New Zealand, and Australia. Azalea viscosa is called Swamp H. in North America.

HONEY-SUCKLE, French. See French Honeysuckle.

HONEY-SUCKLE ORNAMENT, a form characteristic of eastern art. It is used in Assyrian, Persian, and Hindu architecture, and wherever used indicates an eastern origin. The Greeks borrowed it from the Persians, and, by refining and improving it, made it one of the most beautiful ornaments of their architecture. It is chiefly used in the Ionic Style (q. v.). See also Grecian Architecture.

HONFLEUR, a small town and seaport of France, in the department of Calvados, is situated on the southern shore of the estuary of the Seine, opposite to, and seven miles distant from the port of Havre. The situation, backed by the Breton Height, is exceedingly pleasing; but it is badly built, dirty, and uninteresting. The commerce of H., once of some importance, has been absorbed in great measure by the vessels, however, engaged in the fisheries, are still owned here, and there is a considerable trade in the export of eggs and fruit to England, and in timber. The principal manufactures are hosiery, chemical products, hardware, and reeds. There are also repair-works and ship-building yards. The harbour is furnished with two light-houses. Pop. 8739.

HONG-KONG ['Frangrant Streams,' but better known now among the Chinese as Kwan Tai Lu, or 'Petitcoast String Road'], a British island off the south-east coast of China, is situated in the estuary of the Chu-Kiang, about 100 miles south-east of Canton. It is nine miles long, from two to six broad, and has an area of about 29 square miles. The capital, Victoria, is situated in lat. 22° 16', long. 114° 8'. Pop. (1861) 119,900, 84,000 of whom were Chinese. The total public income in 1861 was £127,241; the expenditure, £199,632, of which £41,217 was laid out on public works.

Island is covered to the south and south-west by mountains, many of the peaks ranging from 1000 to nearly 2000 feet high. The mountains consist chiefly of granite, serpentine, and trap; granite quarries are skilfully worked by the Chinese. The climate is still very unhealthy for Europeans, though not so bad as it was in the earlier years of the colony, when the ground was first opened for purposes of building. For about six months, from May to October, the heat is oppressive in the extreme, being accompanied with much rain and damp, and the city of Victoria is so situated as to be shut out from the refreshing influence of the south-west monsoon. During four of the winter months, the weather is cool, dry, booming, sometimes even cold; but the change from the perspiration of summer to a dry cold is apt to produce dangerous diseases, more especially of the kidneys. The temperature in summer ranges from 83° to 96°, and in winter from 40° to 57°, the men and the wind, from the north, are the principal cause of the climate. It is situated on the north-eastern coast of the island, and separated from it by a narrow channel varying from half a mile to four miles in width, is the Kow-lung Peninsula, a strip of coast territory and portion of the township of the same name, which was ceded to the British government by the convention of Pekin, October 24, 1861.

Victoria, the chief town, is situated on the northern shore of the island, on a small bay surrounded by mountains. It is laid out in magnificent streets, has increased with astonishing rapidity, and is one of the most beautiful British possessions in Asia. Its harbour is commodious and safe; its roadstead has a depth of from three to seven fathoms, and is also commodious, as for future enlargement. Selling and repairing-docks for the ships of the naval station of the sea of China have been established here; merchant-vessels are also repaired here. Between Victoria and the mainland, Macao, Shanghaé, Bombay, Calcutta, &c., frequent and regular communication by steam is maintained. The magnificent harbour of H. presents a most stirring appearance. Steamers and sailing-vessels are arriving and departing to the place of its destination, without touching at this British settlement; in the same manner, hardly any of the towns and not much of the silks and other manufactures produced in the dominions of H. is chiefly in an opium, in supplying war and other vessels with stores, in repairing vessels, and in the transfer of passengers. In 1875—1878, the value of the manufactures and produce imported into India from this island was £559,474. Already one of the most flourishing of British colonies, H. is probably destined to further extension and importance, and will rise with the gradual increase of the commerce of Eastern Asia. In 1841 by this island was ceded in perpetuity to her Britannic Majesty by the treaty of Nankin, having been occupied as a preliminary measure in 1841. Its affairs are ruled by a governor (at present, 1862, Sir Hercules Robinson) and legislative council, who have the seat of administration here.

HONITON, a small market-town, and municipal and parliamentary borough of England, in the county of Devon, is beautifully situated in a graceful and highly cultivated valley, near the left bank of the Otter, 16 miles north-east of Exeter. The Old Church contains a light and elegant oak-screen, erected in 1482 by Courtenay, Bishop of Exeter. H. has long been famous for the lace, called from the town in which it is the chief branch of manufacture, 'Honiton Lace.' This lace is made by hand on a 'nolose'; its manufacture was introduced into England by the Lollards during the reign of Elizabeth. The vale of Honiton is famous for its butter. Pop. of parliamentary and municipal borough in 1861, 330. The borough returns two members to the House of Commons.

HONOLULU, a seaport in lat. 21° 18' N., and long. 157° 35' W., on the south-western or leeward coast of Oahu, one of the Sandwich Islands (q. v.), is perhaps the only spot in Polynesia that can fairly claim to be reckoned as an integral part of the United States. H. is 38 miles distant from the capital of the island, Honolulu. Being the seat of government, as well as the centre of trade, it is, in every sense, the metropolis of its own group, which is at once the largest and the most important of all the islanded clusters. But beyond this, its intrinsic advantages, and the absence, or at least the distance, of rivals along the surrounding waters, in any direction, have combined to render it an entrepot between the opposite shores of the Pacific. Besides attracting thousands of whalers for repair and supply, it occupies a most convenient position on each of the three great thoroughfares of its own giant ocean.
HONORIUM—HONOUR

Tengh Osabu, in common with the rest of the chain, is evidently of volcanic formation, yet the red, which forms the breakwater of the harbour of L., is of coral formation. The temperature of the town ranges between 70° and 87°2 in August; so that, roughly computed, the annual mean is 75°-5, with a divergence in either direction of only 7°.6. The tropical heat is moderated by the influence of the sea, fomenting, consisting chiefly of natives, numbers fully 10,000. This mott of traffic has, for sixty years, maintained the unity, and, through the unity, the peace of the once independent and hostile tribes of the Hawaiian Archipelago. In 1857 the departures were represented by 60 vessels, and 23,183 tons; and the arrivals by 75 vessels, and 24,200 tons. In the same year, the exports amounted to 47,997 dollars, the imports to 1,401,576, and the customs to 135,640 dollars. In H. are to be found consuls from the United States, the Hanse Towns, Chili, Denmark, Spain, France, England, Hanover, Oldenburg, Peru, Prussia, Russia, and Sweden.

HONORARIUM, a term sometimes used to denote the fees payable to counsel or physicians, became the frequent word with historians; and they are paid beforehand, and not on the vulgar theory of payment for services rendered. The legal effect which followed was, that neither counsel nor physicians, if not paid their fees beforehand, could bring an action against the client to recover them. This is still the case in the United Kingdom as to counsel, but not as to registered physicians, who can now recover their fees by action. The law as to how far a country can validly make a special agreement for a fixed sum, and sue for it, has been favourably discussed in England in the late case of Kennedy v. Brown, but has not yet been decided.

HONORIUS, Flavii, second son of Theodosius the Great, was born, according to the best authorities, 9th September 384 A.D. On the death of his father, the empire was divided into two parts, H. receiving the western half, with Rome as his capital; but being only ten years old, was put under the guardianship of Stilicho (q. v.), who was all his life the de facto ruler of the Western Empire. H. first took up his residence in Italy, where, in 398 A.D., he married Monica, the daughter of Stilicho. The most important events of H.'s reign were the various treaties concluded with the German nations. Under Emperor Danilo; the rigorous persecution of pagans in 399; and the devastation of Northern Italy by Alaric and his Visigoths in 400-403. Stilicho was then in Germany; but on his return, he speedily cleared the country of the invaders, after totally defeating them at Pollentia (March 406). Another irruption of barbarians, under Radagaisus, took place in 405-406, which was again repelled by the powerful arm of Stilicho. Nevertheless, this brave soldier and able minister lost the favour of his weak and worthless master, and was treacherously slain at Ravenna, 408 A.D. Alaric was not slow to take advantage of the opportunity afforded him. In 408 A.D., he invaded Italy, and besieged Rome, which only escaped on payment of a heavy ransom; and in the following year he again besieged and took it, raising Attilus to the imperial purple. The death of the invader in 410 A.D., after having a three years' reign upon the Italic soil, and as the new champion of the falling empire arose in the person of Constantius, who suppressed the rebellions of Constantine, Jovinus, and Sallustius in the northern provinces, and of Heraclianus in Africa. He was now appointed the colleague of H. in the consulship, and received in marriage the hand of Placidia, sister to H., along with a share in the empire, which he did not long enjoy, as his death took place a few months after. The Gothic and German tribes had for some time been slowly but steadily encroaching upon the borders of the West. H.'s reign saw Spain, Gaul, and Pamonia, some of the finest provinces, snatched from its grasp. He died 27th August 423. H.'s character presents few salient points. He was weak and dishonest, and when excited by fear or jealousy, cruel and treacherous, a trait well brought out in his treatment of Stilicho and Constantine.

HONORIUS, the name of four popes.—Honorius I. has been the subject of much controversy, not alone between Catholics and Protestants, but also between the Gallican and Ultramontane schools of Catholics themselves. He was born of a consular family in Campania. Of his early history, little is known, except that he took an active part in bringing to a close the disputes which arose in Northern Italy about the controversy of the Three Chapters (q. v.). On the death of Boniface V., in 625, he was elected Bishop of Rome. His general administration of church affairs has been favourably judged by historians, and his name is especially connected with the history of the paschal controversy in Ireland, and with that of the early Anglo-Saxon Church. But his pontificate is particularly memorable on account of the Monothelite heresy. See Monovorosism. H. is connected therewith rather negatively, than by any positive participation, in the dissemination of the Monothelite doctrine. While the controversy was yet new in the West, Sergius, Patriarch of Constantinople, wrote to H., to explain to him the Monothelite doctrines in the most favourable light, and to suggest that it would be most desirable to impose silence on both parties, in a dispute which really did not affect the substance of the Catholic doctrine. H., mistimed it is alleged by this statement of Sergius, consented, and even expressed himself in language which would appear to condemn the doctrine of two wills in Christ. The Catholic historians, however, maintain, that in thus declining the belief of two wills in Christ, H. merely denied the existence in Christ of two concordant or conflicting wills, that is, of a corrupt and sinful human will opposed to the divine will. It is not easy, however, to account for the -decree of the sixth general council, in which H. is anathematized in company with many others, of whose heterodoxy there can be no doubt. But the defenders of H.'s reply, that although the sixth council certainly does include H. in one common condemnation with a group of heretical teachers, yet the explanation appended to the condemnation of the former, viz., that 'he had not by the exercise of his apostolic authority extinguished the rising flame of heresy, but by neglecting it, favoured its progress,' clearly alludes to the error of judgment described above, by which, although himself personally orthodox, he enjoined silence on the controversy at a time when a more far-sighted ruler would have felt it his duty to interfere by a clear and explicit declaration. On the whole, they maintain that, however H. may by his imperious silence have compromised the interests of orthodoxy, he did not put forth any such dogmatic declaration as can fairly be regarded, whether by Protestants or by Gallicans, as irreconcilable with the strict ultramontane doctrine of infallibility, inasmuch as the doctrine denounces as 'speaking from the apostolic chair,' H. died in 638. Some letters of his are preserved in Labbe's Coll. Conciliorum, vol. iii.

HONOUR, ACCEPTANCE FOR, a phrase used in
HONOURABLE, RIGHT HONOURABLE, AND MOST HONOURABLE—HOOD.

the law of bills of exchange, to denote that a stranger volunteering to accept a bill out of respect to a foreign party issuing the bill to persons in this country, who refuse to accept it, in which case the stranger accepting, incurs certain responsibilities.

HONOURABLE, RIGHT HONOURABLE, AND MOST HONOURABLE; titles given in the United Kingdom to Peers, their families, and persons holding certain public situations. A Marquis or Marchioness is styled Most Honourable, a Peer (temporal) or Peeress of a lower grade, whether by right or by courtesy, is Right Honourable. The title Right Honourable is also bestowed on the younger sons of Dukes and Marquises, and their wives; and on all the daughters of Dukes, Marquises, and Earls; and Honourable on the younger sons of Earls, and all the children of Viscounts and Barons. Privy Councillors, the Lords Mayor of London, York, and Dublin, the Lord Advocate of Scotland, and the Lord Provost of Edinburgh, are also entitled to the prefix Right Honourable; and Maids of Honour, Lords of Session, the Supreme Judges of England and Ireland, to the title of Honourable. Members of the House of Commons, though Honourable is not prefixed to their names, are distinguished as the 'Honourable member for —'. and the East India Company has been held entitled to the same prefix. In America, the characteristic love of title has been shown in the practice of attaching Honourable to the names of governors of states, judges, members of congress, and other public functionaries.

HONOURABLE ORDINARIES, in Heraldry. See ORDINARIES.

HONOURS, MILITARY AND NAVAL. See SALUTERS.

HONOURS OF WAR, the term used to express the privileges allowed to a garrison surrendering, either in consideration of a brave defence, or from some other cause. Many degrees of honour may be paid to a vanquished enemy, according to the generosity or judgment of the victorious commander-in-chief. In some cases, the garrison is allowed to march out in full arms, drums beating, colours flying, &c.; at another time, the conquered force will only be permitted to advance silently to the front of their works, there to ground or pile arms, and to return about, to retain their lines as prisoners of war. Occasionally, the capitulation will provide that the garrison shall deposit their arms and warlike stores at some specified spot, and then march on to their own territory on parole of not serving during the existing war against the victors or their allies.

HONTHEIM, JOHN NICHOLAS VON, was born at Treves in 1701. He was educated in the Jesuit school of his native city, studied canon law at Louvain under the celebrated Van Eszen, and afterwards taught it for ten years at Treves, of which see he became conductor in 1748, with the title of bishop in paribus infidelium. He is the author of two voluminous works on the history of Treves, Historia Trevirensis Diplomatica (3 vols., fol., 1760), and Provovnia Hist. Trevirensis (2 vols., fol., 1757). But his literary career is chiefly memorable for a theological essay, which, although with very mean pretensions to learning, by the novelty and boldness of its views, created an immense sensation in the time in which it was written. The title of this work, which was in Latin, and dedicated to Pope Clement XIII., is "On the State of the Church and on the Legitimate Authority of the Roman Pontiff," a work composed with a view to the reunion of Christian sects. The name of the author was for a long time unknown, the work being published under the nom de plume of Justinus Febronius (a name said to be taken from that of his niece, who was called Justinus Febroniam), whence the system of church government which the work propounds has been called Febronianism (q. v.). His scheme may be described as a very exaggerated instance of Gallicanism, as it adduces as an element of congregationalism superseded. The work immediately after its appearance was condemned by Clement XIII., as well as by many individual bishops. It drew forth a number of replies, the most important of which are those of Zaccaria (1767) and Ballerini (1768). Pius VI., in 1778, required from H. a retractation of these doctrines. This retractation, however, was modified by a subsequent Commentarius, published at Frankfurt in 1781, to which, at the desire of the pope, Cardinal Gerdil replied. H. eventually made full submission to the church. He died in his 90th year, at Montpunten in Luxembourg, September 1798. — See Menzel's Neuer Geschichte der Deutschen, xi. 406, and foll.

HONVÉD (Land-defenders), the name given in Hungary under the earlier kings to the national armies. With the disappearance of these, the word too disappeared; but in the summer of 1848 it was revived, and applied first to those Hungarian volunteers despatched to the south against the Servians, and subsequently, when the war with Austria really commenced, to the whole patriotic army. Still, in common parlance, the term Honvéd is used only with reference to the Hungarian irregulars.

HOOBLY, a town of Dharwar (q. v.), in the presidency of Bombay, stands in lat. 15° 29' N., and long. 75° 13' E. It contains 15,000 inhabitants, and is one of the principal cotton-marts in that section of India. A good road has been constructed to the Malabar coast, by which the raw cotton of the neighbourhood is easily and cheaply transported for shipment.

HOOD, ROBIN, the hero of several old ballads and traditional stories, which generally represent him as an outlaw and a robber, but of a gallant and generous nature, haunting the depths of Sherwood Forest, Nottinghamshire, and of Barnsle Forest, Yorkshire, in an early era of English history, which it has hitherto been customary to fix in the 12th century. The earliest authentic notice of him is that of a Poem on the Hero of Piers Plowman, dating from between 1335 and 1365: 'rhymes of Robin Hood and Randolph Earl of Chester' are there alluded to. About 1485, Wynkyn de Worde printed a poem of considerable length, entitled The Lytell Geste of Robin Hood—apparently a series of rude popular ballads strung together, being probably a modification of the 'rhymes' spoken of in Piers Plowman. Thus we see evidence for a consider- able antiquity to the ballads commemorating Robin H., a collection of which filled two little volumes printed by Ritson in 1785. It is also certain that, in the early part of the 16th c., there was a widespread circulation of annual rustic sports and miscellaneous verses, under the name of the Robin Hood Games, in which the deeds of the hero, and of his companions, Little John, Friar Tuck, &c., and of his sylvan mistress, Maid Marian, were represen- ted. The attacks extorted from the Established Church by the Reformers had some difficulty in putting them down. In the ballads and the games alike, Robin was always exhibited as a valiant man out of sorts with fortune, giving to the poor much of what he had to live on, and armed with bow and quarter-staff, and almost unfeudingly
victorious in personal encounters with whatsoever opponent.

In addition to these evidences of the existence of such a hero, we must remark that his grave has for ages been pointed to in Kirklee Park, Yorkshire, by a flat stone on which was carved a flowery cross.

While there could be little doubt that some such predatory outlaw as Robin H. once existed, and that he was a character to excite, generally speaking, the affection of the king and the compassion of the people, there was a want of documentary evidence regarding him, until the publication of a tract by the Rev. Joseph Hunter in 1832. In this brochare, it is, first, shown that one of the ballads represents Robin as going, by the invitation of ' Edward our comely king,' to meet him at Nottingham; as there accepting service with his majesty; and as accompanying him to court; where, however, becoming sick almost to death with that kind of life, he did not remain above 15 months; after which he retired, and resumed his wonted free and jovial life in the forest. Mr Hunter then proceeds to show that King Edward II. in 1235 made a project, which, if he had followed it out, would have connected the course of which he came (November 9) to Nottingham; that in the exchequer accounts between March and November of the ensuing year, among the 'wages paid to the defraauders of the king, Robin H., his wages were paid, occur those of ' Robin and Synon Hol;' and that finally, at the latter date occurs an entry— Robin H., heretofore one of the porteurs, because he could no longer work, received as a gift, by command, £5; the name from this time appearing no more. Mr Hunter likewise ascertained that, at a date six years antecedent to the royal progress above mentioned, the name of ' Robertus Hool;' is found in the court-rolls of the manor of Wakefield, as that of a suit at assize for the breach of land. The probability therefore is, that Robin H. lived and acted as the ballads represent him only a few years before the era of Pierr Ploughman, and really passed from wild forest life into the royal service for a brief space—an adventure which might appear as the most incredible attributed to him, if we did not know something of the whimsical and puerile character of Edward II., which was such that he did not disdain occasion to meddle, for instance, in playing at chuck-farthing with his servants. Mr Hunter further deemed it likely that H. was one of the yeomen who joined the discontented barons under the Earl of Lancaster, and were ruined by the failure of their enterprise. If so, his life in the forest might be rather a sort of guerrilla warfare than a practice of simple rapine; and hence it might, in some measure, arise that the 'gestas' of Robin H. became the subject of so much romantic and affectionate sentiment on the part of the community.

HOOD, THOMAS, was born in London in 1798, and after leaving school was placed in the counting-house of a Russian merchant, but his health failing, he was sent to Dundee. At the age of 17, he returned to London, and engaged himself to learn the art of engraving with his uncle. In 1821, he was offered the post of sub-editor of the London Magazine, which he accepted, and at once entered upon its duties. Debtor, it is said, he continued it for nine years. He edited The Gems for one year, contributing to its pages his striking poem entitled Eugene Aram's Dream. In 1831, he went to reside at Wanstaud in Essex, where he wrote his novel of Tydsele Hall; but pecuniary difficulties supervening, he returned to London in 1835. In 1838, he commenced the publication of Hood's Own, to which his portrait was attached. Health failing about this time, he went to reside on the continent, and remained six years. In 1843, he published Up the Rhine, the idea of which was taken from Humphry Clinker. On his return to England, he became the editor of The New Monthly Magazine, and on his withdrawal from its management in 1845, commenced Whimsicaties, which was chiefly of his contributions to that serial. In 1844, he started Hood's Magazine, and contributed to its pages till within a month of his death. During his last illness, Sir Robert Peel conferred on him a pension of £100 a year, which was transferred to his wife. He died on the 3d May 1845, and was buried in Kensall Green Cemetery. Compare Memorials of Thomas Hood, Collected, Arranged, and Edited by his Daughter, with a Preface and Notes by his Son (2 vols. 1860).

H. takes a high place both as a humorist and as a serious poet. He is great at once in comedy and pathos, and he sometimes curiously minglest and combines both. He is at once a punner, he connects far-separated words and ideas by the most subtle analogies, and sends them loose. Much of his comedy, however, is verbal and shallow, and will not be soon forgotten. It is as a poet that he will be remembered. His Eugene Aram's Dream, Song of the Shirt, and Bridge of Sighs, are among the most perfect poems of their kind in the English language.

HOOD, VISCOUNT (SAMUEL HOOO), English admiral, was eldest son of the Rev. S. Hood, vicar of Thorncombe, Devonshire, and was born, 1724. At 16, he entered the royal navy, was made lieutenant in 1746, and post-captain in 1756. In 1759, being in command of the Victory, 32 guns, he engaged a French 50-gun ship, which he took after a desperate action of four hours. In 1777, he was made commissioner of Portsmouth dockyard, and next year received a baronetcy. He was then made rear-admiral, was sent to the West Indies to reinforce Rodney, and commanded a division in the engagement with the Comte de Grasse, April 12, 1782. He was made a peer of Ireland by the title of Baron Hood. In 1793, he was made commander-in-chief of the Mediterranean fleet, and took possession of the island of Toulon; but the French republican army, in a great force, compelled him to evacuate it, after destroying or carrying away the principal part of the shipping, firing the arsenal and public stores. He then sailed for Corsica, which, after a campaign, he annexed to the crown of Great Britain. In 1796, he advanced to the rank of a viscount of Great Britain, and made governor of Greenwich Hospital. He died at Bath, January 27, 1816.

—His younger brother, ALEXANDER HOOD, served as rear-admiral under Lord Howe, was second in command at Lord Howe's victory of the 1st June 1794, obtained a victory over the French fleet in 1795, and was made, in 1796, Baron, and in 1801, Viscount Bridport. He died in 1814.

HOOD-MOULDING. See DRIPSTONE.

HOOF. (See HORSE TONGUE.) The healthy soundness of the horse's foot is mainly preserved by permitting it to grow uninjured by the rasp and knife (see HORSE-SHOEING), whilst its toughness is secured, and undue dryness and evaporation prevented, by a generous, daily, but not wet, sole, and frog with a little glycine, or a mixture made by melting together a quarter of a pound each of tar, honey, bees' wax, and glycine, with a pound of lard. Softness and brittleness of the hoof, which
HOOFT—HOOKE.

As fruitful sources of cracks and Corns (q. v.), may be remedied by the regular use of such dressings, by placing the feet for several hours daily in thick woolen swabs, kept cool and moist by frequent and drainage with oil, was the principal mode of effecting more healthy growth of horn by occasional mild blisters round the coronary band. Cracks, or sand-cracks, as they are termed, mostly occur amongst horses much upon the roads, cause lameness, and consume great quantity of stock. When the hooves are too polished, thinning away of the crust about the crack, and perfect rest, are essential. After the earlier heat and tenderness are removed, a hot iron should be drawn at right angles to the crack, both above and below, so as to separate the diseased from the sound horn. Waxcd thread or fine wire should be wound round the hoof, and a sound growth of horn stimulated by a blister round the coronet. The horse's hooves are too hard and coarse to be employed for the making of the better class of combs and buttons, for which purpose the hoofs of cattle, to the value of nearly £2000, are annually imported. They are, however, largely used by manufacturers of prostiate of potash and artificial manures.

HOOFT, Pieter, a Dutch historian and poet, was born at Amsterdam, 16th March 1651, studied at Leyden, and travelled in France, Germany, and Italy. He died there the 5th of June, May 21, 1674. The chief historical works of H. are Hist. Leven van Koning Hendrik IV. (Amst. 1629—1632), and Niederländische Historien (2 vols. Amst. 1642—1654; most recent edition, 1820—1823). The latter of these is still of the greatest value, and is considered one of the classics of Dutch literature. H. also translated Tacitus into Dutch. As a poet, his Minnedigte have not been surpassed, if even equalled, by any other Dutch verses of the same age. His Letters were published by Huydecoper in 1738. H. has exercised an important influence on the development of the Dutch language.

HOOGHLY, a river of Bengal Proper, is formed, in lat. 23° 25' N., and long. 88° 22' E., by the junction of the first two offsets of the Ganges, the Bhagurtti and the Jellinghi. From the point in question, the stream, strictly so called, is 123 miles long; the estuary, as far as Seangor Roads, measuring 35 miles more. From this point the river reaches the sea, the H. is the most available for navigation. In the dry season, the tide is felt nearly up to Chandernagore, 17 miles above Calcutta. During the south-west monsoon, this is embayed by a phenomenon known as 'The Bore' (q. v.). Up to Calcutta, the draught is seldom less than 17 feet; but the bottom is said to be sitting up. At its entrance, too, the H. is much encumbered with shoals.

HOOGHLY, a city of Bengal Proper, stands on the right or western bank of the river Hooghly, 27 miles north of Calcutta, in lat. 22° 54' N., and long. 88° 22' E. It is estimated to contain 12,000 inhabitants. Here is a college for English and Asiatic languages, which owes its existence mainly to the munificence of a native; and in connection with this establishment are several schools. The district of Hooghly contains 2080 square miles, and a population of 1,520,540.

HOOK, Theodore Edward, a celebrated novelist and essayist, was born in London, September 22, 1788, and educated at Harrow. In 1805, at the age of 17, he produced an operatic farce called the Soldier's Return, which was very successful; and before that year he had written twelve other operatic pieces and farces, all of which were popular at the time. His ready wit, sparkling humour, and wonderful powers of improvisation, made him the delight of society; and having pleased the Prince Regent by his feats of mimicry, he was appointed (1813) accountant-general and treasurer of the Mauritius, with a salary and allowances amounting to nearly £2000 a year. These offices he held till 1818, when the discovery of a considerable deficiency in the military chest caused him to be arrested and sent to England, and his effects were seized. The public demands for letters towards appeared, had been committed by his deputy, who destroyed himself. On obtaining his liberty, H. supported himself by writing for the newspapers and magazines, and on the establishment of the John Bull, weekly Tory newspaper, in 1820, he was appointed its editor. From his connection with this bold, clever, and, at that time, virulent, periodical, he derived, during its prosperous state, fully £5000 a year. In August 1823, for his debt to the government, amounting to about £12,000, he was arrested under an Exchequer writ, and his property sold. He remained within the rules of the King's Bench till May 1825, when he was released from custody. In 1824 appeared, in 3 vols. 8vo, the first series of his Sayings and Doings, which yielded him £2000. A second series followed in 1825, and a third in 1828, for each of which he received 1000 guineas. Several other three-volume novels were published by him in rapid succession, such as Maxwick, 1829; Love and Pride, 1833; Gilbert Gurney, which contains a sort of autobiography of himself, 1835; Jack Brog, 1837; Richard Deth, and Marriages, 1839; Gurney Married, 1839; &c. He died August 24, 1841.

HOOK, REV. Walter Farquhar, D.D., son of the Rev. James Hook, Dean of Worcester, was born at Worcester about the beginning of the century, and educated at Christ-Church, Oxford, where he graduated in 1821. After holding some minor preferments in the church, he was appointed Vicar of Leeds in 1837, and a few years ago Dean of Chichester. The English Church does not possess a more zealous or laborious son. In 1836, Dr. Hugh Ripon, on taking leave of the clergy of his diocese, stated that twenty churches had been built in Leeds through the exertions of Dr. H., while schoolrooms had been provided for more than 10,000 children, with a salary amounting to £2000. Among his works are:—An Ecclesiastical Biography, containing the Lives of Ancient Fathers and Modern Divines (8 vols. Lond. 1845—1852), A Church Dictionary (9th ed. 1839), Sermons suggested by the exemplars of Lord and Lord, and Miscellaneous Divines (2 vols. 1847), On the Means of Rendering more Effectual the Education of the Peasle (10th ed. 1851), and Lives of the Archbishops of Canterbury (2 vols. 1861).

HOO KAH. See PIPE.

HOOKE, Robert, an English natural philosopher, born at Freshwater, Isle of Wight, July 18, 1635, was educated at Westminster school, and at Christ-Church, Oxford. In 1662 he was appointed curator of experiments to the Royal Society, and in 1677 became its secretary; in 1684, professor of geometry in Gresham College, London; and in 1666, surveyor for the city of London, a most lucrative appointment. He died at Gresham College, March 3, 1703. H. was a man of extraordinary inventive powers, and has justly been considered as the greatest of philosophical mechanics; the wonderful sagacity, nay, almost intuition, he shewed in deducing correct general laws from mere phenomena, was never before since his time equalled. There was no important invention by any philosopher of that time which was not in part
HOOVER.

anticipated by Hooker. His theory of gravitation subsequently formed part of Newton’s; he antici-
pated the invention of the steam-engine, and the
discovery of the laws of the constrained motions of
planets. Among his other completed discoveries
are, the law of the extension and compression of
dastic bodies, ‘ut tensio sic vis;’ the simplest theory
of the arch; the balance-spring of watches and the
anchor-escape-gears; the permanency of the
temperature of boiling water. The quadrant, tele-
scope, and microscope are also materially indebted
to him.

HOOKER, RICHARD, author of the Books of
Ecclesiastical Polity, and one of the most illustrious
of English theologians, was born in the city of
Exeter, or its neighbourhood, about the year 1554.
He was early distinguished for his “quick apprehen-
sion of many perplex parts of learning,” and
attracted the notice of Jewell, Bishop of Salisbury,
through whose influence he was sent to Oxford about
his 15th year. He was placed at Corpus Christi College.
He was advanced first to the dignity of scholar, and then of fellow of his college. After
about the 4th year’s residence in his college as a fellow, he entered into sacred order, and
was appointed to preach at St Paul’s Cross. Hither
all the power and eloquence of the church found
their way in the 16th century. To H., however,
the desire of fame was not sufficiently apparent; his
considerable, according to Walton’s account; and
the more as the weather proved very unfavourable
for his journey; ‘but a warm bed and rest, and
drink proper for a cold, given him by Mrs Church-
man, and the large audience of young attendants,
enabled him to perform the office of the day, which
was on or about the year 1581.’ Mrs Churchman’s
kindness proved too much for the simple-minded
theologian. He was led, evidently without due
consideration, to a marriage which proved unhappy.
This marriage of H. is, as is known to all, was far
from proving a source of happiness—a result
that could scarcely have been expected from its
commencement. Walton’s description of the visit
of his two old pupils, Edwin Sandys and George
Crammer, and ‘Richard called to rock the cradle’
from their company, is among the most charac-
teristic sketches of this fine old writer. The visit
was due to the suggestion of the Rev. Dr Hooker, in
Buckinghamshire, where H. had settled in 1584, as a country
priest, after his marriage. He was transferred ere
long to the mastership of the Temple, by the
patronage of Archbishop Whitgift; and here he was
engaged in controversy with Puritanism, out
of which his great work arose. Travers, one of
the most zealous of the Elizabethan Puritans, was
his colleague in the Temple. Travers was more
attractive and popular orator, if the less profound
thinker. The union was not a happy one. The
congregation ‘ebied in the forenoon,’ Fuller tells us,
‘and flowed in the afternoon.’ ‘Pure Canterbury’
was in the ascendant in the morning, ‘Geneva’ in
the afternoon. H. soon tired of the contention in
the congregation, and the indifference of the majority
to his ministry. He accordingly applied to the arch-
bishop, who presented him, in the year 1591, to the
rectory of Boscom, in the diocese of Salisbury, and
six miles from the sea. Here he remained four
years, busily employed with his great work, which
his experience in the Temple probably prompted.
The first four books of the Ecclesiastical Polity
appeared in 1594. In the same year, he was trans-
ferred to the living of Bishopshope, near Canter-
bury, where he spent the few remaining years of
his life, and gave to the world the fifth book of
the Polity. The remaining three books were posthumous.
About the year 1600, in the 46th year of his age, he
cought cold in his passage from London to Graves-
end, and gradually sunk under the weakness which
followed.

H. will always be esteemed one of the most illustri-
uts thinkers and writers, not only in English
theology, but in English literature. He is alike
comprehensive and profound, tranquil and eloquent.
He is speculative without mysticism, and earnest
without declamation. He searches all the depths
of the soul and rises to all the heights of his subject, without
ever forgetting the simplicity of the Christian or
breaking the charm of catholic association that binds
all its parts together. More than anything, he is
wise and judicious in the highest sense of that
word; and it is the light of lofty and calm wisdom,
shining through his pages, that continue to make
them a delightful and excellent study, when most
of the contemporary theological works are forgotten.

HOOKER, SIR WILLIAM JACKSON, F.R.S.,
a celebrated English botanist, was born at Norwich
in 1783. He was instructed by his friends for
a mercantile life, but his natural love of botany
induced him to devote himself to that department
of natural history. His first work was a Journal
of a Tour in Iceland in 1811, which attained such
popularity that he issued a second edition of
it in 1813. From that time to the present, he has
been almost incessantly engaged in the publication
of botanical works, which are far too numerous
for a full enumeration in this article. His inves-
tigations on the British Juniperaceae and Mosses,
led to his appointment to the chair of botany in
the university of Glasgow, where he lectured with
great success till 1841, when he resigned his pro-
tership on becoming director of the gardens at
Gardens at Kew, an office which he still fills in
a most efficient manner. Those only who recol-
lect the state in which these Gardens were at the
time of his appointment, can fully appreciate
the improvements which have taken place during
his management. His name is enrolled in the lists
of all the scientific societies at home and abroad;
and he was knighted in 1836, on account of his high
scientific acquirements. The following are some of
the most important of his works: 1. The British
Juniperaceae (1812—1816); 2. Musco-
ologia Britannica, containing the mosses of Great
Britain and Ireland (1818); 3. Musci Eczoicici (2 vols.
1818—1829); 4. Flora Helvetica (3 vols. 1825—1827);
5. Icones Floricum (in association with Dr Greville),
(2 vols. fol. 1826—
1837); 7. The British Flora, 1830, a work that
has gone through seven editions; 8. Flora Boreali-
Americana, the Botany of the Northern Parts of
British America (2 vols. 4to, 1829—1840); 9. Illus-
trations of the Genera of Ferns (1838—1842); 10. A
Century of Orchidaceous Plants, (4to, 1848); 11. The
Botany of Captain Beechey’s Voyages to the Pacific
and Bering’s Straits (in conjunction with Dr
Walker Arnot), (1831—1841); 12. The Victoria
Regia; 13. Icones Plantarum (10 vols. 1827—1860);

HOOKER, JOSEPH DALTON, M.D., F.R.S., a
distinguished living botanist, was born at Glasgow
in 1816, and is the only surviving son of Sir William
Jackson Hooker (q. v.). He was educated for the
medical profession, and graduated as M.D. at the
university of Glasgow; accompanied the antarctic
expedition under Sir James Ross in 1839, nominally
as assistant-surgeon to the Erebus, but in reality
as surgeon to the Terror; and after the return
of the expedition, spent over two years on the
Pacific coast. In the year 1848, he started on another
expedition with the view of investigating a tropical
flora, and spent about three years in examining the
vegetation of the Sikkim Himalayas. He returned to
HOOKS AND EYES—HOOKING-COUGH.

England in 1851, and shortly afterwards published his Himalayan Journals, in two volumes, which contain a large amount of scientific information on natural history, physical geography, and meteorology. The botanical collections he made in India were very valuable, the combined Herbaria of his fellow-traveller, Dr Thomson, and himself, embracing nearly 7000 species of plants, including an immense number of duplicates; and the number of new plants—especially of Rhododendrons—that have been introduced into our gardens in consequence of this expedition, is very considerable. He is assistant to his father at Kew, and one of the vice-presidents of the Royal Society. Besides various important papers in the Transactions of the Linnaean and other learned societies, he has published the following botanical works: (1.) The Botany of Sir James Ross’s Antarctic Voyage, including three separate works—viz., The Flora of New Zealand, The Flora of Tasmania, and The Flora of Lord Auckland’s Islands; (2.) Illustrations of Sikkim-Himalayan Plants; and (3.) The Rhododendrons of the Sikkim Himalaya. No one since Humboldt has done so much as the subject of this notice to enlarge our knowledge of the geographical distribution of plants.

HOOKS AND EYES. These small articles are largely used in millinery for dress-fasteners, and are of great utility. Formerly, they were made by hand, the wire of which they were formed being bent into the proper shape with pliers; now, however, they are entirely made by machines of great simplicity and beauty. With a pair of them it is possible to make 200 hooks, and the same number of eyes, in one minute. The operations of the machines are, first, to draw the wire forward from the supplying reel, then cut off the length required for hook or eye, as the case may be; a sinker then descends and forces it into a slot, by which it is bent, and two projecting caps, acting at the same time on the two ends, bend them over so as to form the lateral loops used for sewing the hook or eye to the garment; then, in the case of the hook, it is passed under another sinker, which forces the doubled wire into another slot, and forms the hook part; one side of the slot, being movable, is made to strike the bent portion of the hook sufficiently to flatten it. It is then complete, and drops out, to make room for another.

HOOK-SQUID, the name commonly given to cephalopod molluscs of the genera Onychoteuthis and Enopledoneotes, allied to the common squids or Calamaries (q. v.), but having the eyes destitute of any covering of skin. The arms have two rows of suckers, the tufted bases much exceed them in length, and are furnished with hooks at their extremities. Hook-squids are found in the Sargasso seas, being often of large size—sometimes six feet long or more—whilst their hooks, their many arms, and their very numerous suckers, and their strong mandibles, entitle them to a place among the most formidable monsters of the deep.

HOOK ASH. See Nettle-tree.

HOOKER, John, an English prelate and martyr, was born in Somersetshire about 1495, and educated at Oxford. In the course of the work of the German Reformers, and of the Scriptures, he was converted to Protestantism, and about 1540 he went to the continent, and spent some time in Switzerland. At the accession of Edward VI., in 1547, he returned to England, and became a preacher in London. In 1559, he was appointed Bishop of Gloucester, but his objections to wearing the Episcopalian vestments caused some delay in his consecration. In 1552, he received the bishopric of Worcester in commendam. On the commencement of Mary’s reign, in 1553, he was committed to the Fleet, where he remained for 18 months, being frequently examined before the council; but continuing firm in the Protestant faith, he was condemned as a heretic and lost his life at the stake at Gloucester, February 9, 1555. He was the author of numerous sermons and controversial treatises.

HOOKING-COUGH, or PERTUSSIS, is an infectious, and sometimes epidemic disease, mostly amongst children, especially in the spring and autumn. Its earliest symptoms, which usually appear five or six days after exposure to infection, are those of a common cold, as hoarseness, a watery discharge from the eyes and nose, oppression of the chest, a short dry cough, and more or less feverishness. This stage, which is called the catarrhal, lasts a week or ten days, when the fever remits, and the cough begins to be followed by the peculiar whooping which characterises the disease, and which is caused by the inspiration of air through the contracted cleft of the glottis. See LARYNX. The disorder may now be regarded as fully developed, and consists of paroxysms of severe coughing, which usually terminate in the expectation of purulent mucus, or in vomiting. During the fit of coughing, the face becomes red or livid, the eyes project, and the child seizes some person or object near him for support. These paroxysms occur at uncertain intervals, but usually about every two hours, and between them the child returns to his play, takes his food with good appetite, and exhibits little or no sign of illness. The disease reaches its height at about the end of the fourth week, after which the paroxysms diminish in frequency, and the patient begins to exhibit evidence of improvement. The second stage may last from two to eight weeks, and is succeeded by what may be termed the convalescent stage, the duration of which is very variable. This is one of those diseases which seldom occur more than once in a lifetime; and hence it probably is that, as few children escape it, it is comparatively rarely noticed in adults. Mortal anatomy has failed to throw any direct light upon its special seat. The proportion of deaths to recoveries in cases of hooping-cough has not been satisfactorily determined, but when there is a severe epidemic, the mortality due to this disease is often very great; the deaths, however, in the majority of cases, occur amongst the poorer classes. This mortality is, in reality, due rather to the bronchitis and pneumonia (or inflammation of the lungs), which are frequent complications of hooping-cough, than to the disease itself.

The treatment of hooping-cough, as long as it is uncomplicated or simple, should not be meddlesome. Nothing that can be prescribed in the early stages will check its natural course, and the object of the physician should be to ward off complications.
and to conduct the disease safely to its natural termination. The diet should consist of milk and unstimulating farinaceous matters. The bowels should be kept moderately open. If the weather is cool, the child should be kept in the house with the temperature of the room at about 60°. A grain, or a grain and a half of ipecacuanha may be given three or four times a day. Slight counter-irritants may also be applied to the surface of the chest; Koch's Embocation, which consists of olive oil, with half its quantity of the oils of cloves and amber, is extensively used for this purpose. Nothing is so serviceable in the last or convalescent stage as change of air, often even when from a pure to a comparatively impure atmosphere; and next to this, the internal use of a solution of binoxide of hydrogen (see Hydrogen, Binoxide of) seems most worthy of trial.

**HooP** (Uppa), a genus of birds of the order Anseriformes, tribe Teniurinctor, and family Upupaide.

To this family are referred also the genera Promerops, Eupinacuus (Plume-birds), &c., natives of warm parts of Asia and its islands, Australia, and Africa, some of which are remarkable for magnificence of plumage. In the whole family, the bill is long and slender, the wings of moderate size or short, the legs short, the toes long, and the claws strong and curved. There are among them, however, great diversities, which have led some to divide them into two families, Upupaide and Promeropside. The genus Promerops and its nearer allies have a close relation to the Melopsid, which they resemble in partly feeding on the sweet juices of plants, in order to which the tongue is extensible and divided at the tip. The hoopoe, on the other hand, exhibit many points of resemblance to the crow family, with which they are connected by the choughs, and some points of resemblance even to hornbills. The tongue is short, and not extensible.

**HOOPS.** See Chinoline.

**HOORN,** a decaying town and seaport of the Netherlands, in the province of North Holland, is agreeably situated on a bay of the Zuider Zee, 20 miles north-north-east of Amsterdam. It was at one time one of the most flourishing towns of its province; but, like all the towns of North Holland situated on the Zuider Zee, it has greatly fallen off in trade and prosperity. There are at H. extensive markets for butter and cheese, and fishing and commerce are carried on to some extent. Here the large nets for herring-fishing were invented. Pop. 8670.

**HOP** (Humulus lupulus), a perennial diocious plant of the natural order Cannabinaceae (q. v.), the only species of its genus. It has long rough twining stems, and stalked 3–5-lobed rough leaves, and is a plant of luxuriant growth and abundant foliage. The male flowers grow in loose branching axillary panicles, and consist of five stamens surrounded by a 5-lobed perianth. The female flowers are in strobiles, or cones, with large persistent, concave, entire scales, which enlarge as the fruit ripens. The part of the hop so much used in brewing, and

![Hop (Humulus lupulus)](image)

sold under the name of hops (q. v.), is the ripened cone of the female plant. Female plants alone, therefore, are cultivated to any considerable extent, it being enough if a few male plants are scattered over a field.

The oil of hops is sedative, analgesic, and narcotic; and hence the value of pillows stuffed with hops in cases of mania, sleeplessness, &c. The bitter principle is not narcotic, but it is tonic. The oil and bitter principle combine to make hops more useful than chamomile, gentian, or any other bitter, in the manufacture of beer; and hence the medicinal value of extra-hopped or bitter beer. The tannic acid contained in the strobiles also adds to the value of hops, and particularly as causing the precipitation of vegetable mucilage, and consequently the clearing of beer. The hop is first mentioned by Pliny as one of the garden plants of the Romans, who, it appears, ate the young shoots as we eat asparagus; and, in fact, many country people in England do the same at the present day. It is a native of Europe and of some parts of Asia, a doubtful native of Britain and of North America. It is more extensively cultivated in the south of
England than in any part of the world, but also to a considerable extent in Germany, France, Flanders, and Southern Russia, and now successfully in North America and in Australia and New Zealand.

The cultivation of the hop was introduced into England from Flanders in the time of Henry VIII., but did not become sufficient for the supply of the kingdom till the end of the 17th Century. For some time after hops began to be used in brewing, a strong prejudice existed against the innovation; and parliament was petitioned against hops, as 'a wicked weed, that would spoil the taste of the drink, and endanger the people.' About 50,000 acres are now employed in the cultivation of hops, chiefly in the counties of Kent, Sussex, Worcester, and Hants; the two former counties producing the best hops in the world. Fields of hops are to be seen as far north as Nottinghamshire.

The hop requires a very rich soil, and its growth is promoted by the liberal application both of organic and mineral manures; although excessive manuring is prejudicial. It spreads rapidly underground by its roots, and is not easily extirpated where it has once been introduced. It is generally propagated by layers or cuttings, which usually grow for a year and a half before being put out. In the United States, plantations, they are generally placed in groups of three or four, at distances of from six to nine feet. Great care is necessary in fastening the stems to the poles when they begin to shoot, setting up any that may be blown down, &c. The stalks, or bines, are taken down from the poles after the hop-picking, and cut and removed, to be used as litter or as manure, for which purposes they are excellent. The fresh bines, which are cut to prevent undue luxuriance in summer, are dried for feeding cattle, and are as good as the best clover hay.

The fibre of the stems is employed to a considerable extent in Sweden in the manufacture of a coarse kind of cloth, which is strong, white, and durable; but the fibres are so difficult of separation, that the stems require to be steeped in water for a whole winter. The hop plant often suffers very much, and the prospects of the farmer are destroyed by the Hop Mildew, and by insect enemies, the worst of which are noticed in the following articles.

HOP FLEA (Haltica concina), a very small coleopterous insect, not quite one-tenth of an inch in length, which often does much mischief in hop-plantations in springing, or in blowing the tender tops of the young shoots. It is of the same genus with the turnip flea (sometimes called turnip-fly), so destructive to turnips.

1. Hop Flea (Haltica concina): <a, natural size; b, magnified; c, a fore-leg; d, hind-leg.

HOP FLY (Aphis Humuli), a species of Aphis (q. v.) or plant-louse, important on account of the injury which in some seasons it does to hop-plantations. It is, indeed, the principal cause of the great difference between the hop crop of one year and of another, causing the variations, and the speculations for which the hop trade is notable.—The winged female is green, with a black head, and spots and bands of black on the body; the legs are long. A few winged females appear about the end of July or August, and the male multitudes are sometimes to be seen by the middle of June, on the under side of the hop-leaves and on the stems. The fly is the great dread of hop cultivators, and no means have been found of arresting its ravages. Lady-birds have been introduced in hopes of rendering some service by devouring the aphides, and restraining their excessive multiplication. It is proposed, in Kirby and Spence's Entomology, that women and children should be employed to pick off the winged aphides on their first appearance.

HOPE, THOMAS, a distinguished author and patron of art, ancient and modern, was born in London about 1770. While still a youth, he travelled over a large portion of Europe, Asia, and Africa, and collected many drawings, chiefly of buildings and monuments, which he employed to attract attention by the splendid decorations which he bestowed on the interior of his mansion in Duchess Street, Portland Place, London, a description of which appeared in his book on Houses and Furniture in 1803, and which completely revolutionised the taste of this country. In 1809, he published his Costume of the Ancients, the influence of which was undoubtedly very great. His essay on the Architecture of Theatres, belonging to the same year, also deserves mention. Three years afterwards appeared his Modern Costumes, and in 1819 his Anacharsis, or Memoirs of a Modern Greek at the close of the 18th Century. This last work is his master-piece. It was published anonymously, and was said by many people to be a production of Lord Byron's, who was greatly flattered by the rumour. It is certainly a brilliant and erudite performance, but is tedious and obscure in many places. It wants the dramatic air of a genuine work of genius, and is now hardly ever read. The only other works of H. worth mentioning, are his essay On the Oratio and Prospects of M., a very h虐待 but rather eloquent piece of writing; and a Historical Essay on Architecture, both of which were published posthumously. He died February 3, 1831.

HÔPITAL, MICHEL DE L', was born at Aigueperse, in Auvergne, in 1505, studied law at Toulouse, and first made himself known as an advocate in the parliament of Paris, and after discharging various public functions, became chancellor in 1569, during the minority of Francis II. France at this time was torn by contending factions. The Guises, in particular, were powerful, ambitious, and intensely Catholic; and when one of the family, the Cardinal de Lorraine, wished to establish the Inquisition in the country, H. boldly and firmly opposed him, and may be said to have saved France from that detestable institution. He summoned the states-general, which had not met for 30 years, and, being supported by the mass of moderate Catholics, he forced the Guises to yield. His speech at the opening of the assembly was worthy of his wise and magnanimous spirit: 'Let us do away,' said he, 'with the diabolical words of Lutherans, Huguenots, and Papists—names of party and sedition; do not let us change the fair appellation of Christians.' He induced the assembly to pass an ordinance abolishing, in a manner, the state, regulating the feudal authority of the nobles, and correcting the abuses of the judicial system. In the following year, he secured various benefits for the persecuted Huguenots;
but politico-religious passions were too fierce and
vindictive, and France was invaded by all and
nothing but blood; and in spite of the most
strenuous efforts which II. could make, the nation
was plunged in the horrors of civil war, ending
rather in the success of the Guises, the political
udorontes of their day. The old patriot, who
loved France too well to be either Huguenot or
ultramontanist, went into retirement, where he heard
the news of the massacre of St Bartholomew, a
crime that broke the unity of France and the
rights of conscience, which broke his heart. He
died 15th March 1578.

HOPKINS, SAMUEL, D.D., an American clergy-
man, and founder of the Hopkinsian theology,
was born at Waterbury, Connecticut, September
17, 1721. Having graduated at Yale College in
1741, he studied theology with Jonathan Edwards,
and from 1743 to 1769 was settled as pastor of
Housatonic, now called Great Barrington, Mass.
achusetts. He then removed to Newport, where he
died December 28, 1803. His writings consist of
a life of President Edwards, sermons, a
work on the millennium, and a system of theology,
repubhshed in Boston, 1832. He is said to be
the hero of Mrs Beecher Stowe's Minister's Wooing.
He was remarkable for his simplicity, earnestness,
and persevering industry, and his peculiar theological
doctrines have been a source of controversy for
a century.—HOPKINSIANS, those who adopt
the theological opinions of Dr Hopkins, are not a
distinct sect, but are by far the most numerous,
in America, in some of the Christian bodies of which
the tenets are generally Calvinistic. They hold most
of the Calvinistic doctrines, and even in their
most extreme form, but they entirely reject the
doctrine of imputation, both the imputation of
Adam's sin and of Christ's righteousness. The
fundamental doctrine of the Hopkinsian system,
however, is, that all virtue and true holiness con-
sist in disinterested benevolence, and that all sin is
selfishness—the self-love which leads a man to give
his first regard even to his own eternal interests,
and not to their being consnmed as sinful.

HOPS. The produce of the hop-plant (see Hop).
The fruit is a little nut, not larger than a grain
of mustard-seed, and between its outer shell and
the inner one, which is like unto a bubble, is an
excretable granular substance called Lupulin, which
also exists as a sort of efflorescence on the surface
of the scales themselves; much of the value of the
hop depends upon the abundance of this substance.
The Lupuline is not a mere powder, but each grain
is a little organised cellular body, of an oval or
round form, and, when seen under the microscope,
has been analysed by many chemists. The follow-
ing is the result of the investigations of Payen,
Chevallier, and Pelletan:

The first year the bines, or stalks, are weak, and
have to be provided with poles. When the bines
die down in autumn, they are cut off, and the
sticks set out, or stacked, and left exposed to
winter the ground is forked over and manured.
The plants are in perfection the third year, when each
requires a pole about 18 or 20 feet in height, to
which the young bines are tied as they grow, with
rushes or hemp. They, however, soon begin to
twine around the poles, and then require no more
tying. In the English hop-gounds, the picking begins
about the middle of September. This is done by
women and children chiefly, some men being neces-
sary to lower the poles and bring the hops within
reach. As the hops are picked, they are taken to the
kist, or hop-kiln, in which they are dried, usually
on horizontal screens of haircloth, through
which the heat of the kiln passes, and the culture
requires to be performed with great care, as the
essential oil is very liable to be volatilised, espe-
cially as the hops are frequently kept from year
to year. When fully dried, they are carried to
the packing-house, and are there pressed into the bags
or pockets, and sewed up ready for sale.

The best varieties of the hop are, the Hill Golding,
the East Kent Golding, Golden Hops, Jones' Hops,
Grape Hops, and Farnham White Bine.

The Golding are the best and richest, and are
used for the finest ales. The Jones' are most valued
for their habit of short growth, which enables the
crower to use shorter poles. The Colegates are very
hardy, and can be grown in poorer countries than
others. The grape hops are also very hardy, and
will do on an indifferent soil; they are also very
prolific.

We also receive them of excellent quality from
Canada and the United States. Until the present
year (1862), hops have paid an excise duty, and have
formed an important part of the revenue, although
a very variable crop, owing to the serious check it
is liable to from insects, fungi, diseases, and the
weather. The average payment for duties for the
last ten years has been about £20,000, from about
80,000 acres of land cultivated with this crop. The
import duties have been nearly £50,000. The duty
is now removed, and it is highly probable that the
cultivation will be very greatly extended.

In a carefully conducted experiment, Dr Ives
obtained 14 ounces of lupulin from 6 pounds of
hops; and as he was sure that he had not removed
it all from the scales and nuts, a fair conclusion was
drawn that the lupulin constitutes a sixtieth of the
whole weight of the best hops. Both the bitter
taste and the preservative character of hops are
supposed to depend entirely upon this material,
whether in the form of fully developed lupuline
grains, or diffused in an undeveloped state in the
structure of the scales. It is, therefore, of the
utmost importance not only to encourage the
development of the lupuline by good cultivation,
but it is equally desirable to make the best use
of it when produced. In furtherance of this, many of
the principal English brewers now use an ingenious
machine made by Mr Handside of Derby, which
first shales off and sifts out the lupuline grains,
and then separates the nuts or seeds from the scales.
The reason for this separation is this: Experience
has shown that much of the aromatic principle
of the lupulin is abraded at a boiling heat; there-
fore only the scales are so treated, whilst the free
lupulin is mashed with lukewarm wort, and the
nuts, after being crushed, are treated in the same
manner, and all are added together when cold. By
this means, the aroma is fully developed, and a
smaller quantity of hops is found to answer fully.

There is a narcotic principle in hops as well as
the bitter and tonic, all of which have led to their
employment in medicine. Such use is, however, very
limited. For the full enjoyment of their employment
in the process of brewing, see BIRR.
lately forming part of the kingdom of Naples—on the 8th December, 65 B.C. His father, who had been born a slave, but manumitted before the poet's birth, was a sourcer (a collector of money for taxation) to be his patron and removing to Rome for the purpose, he gave him the culture usually bestowed on the children of the highest classes. Having finished his youthful studies at Rome, he was engaged on higher ones at Athens, when the assassina-
tion of Julius Caesar threw the whole Roman world into confusion, and dragged H. himself—in his 21st year—into the civil war which followed. Brutus coming with Cassius to Greece, made H. a tribune, and he served with the Republican leaders in that rank until the fatal field of Philippi put an end to their campaign. Brutus and Cassius destroyed themselves. H. made his submission, and returned to Rome. With what was left of his patrimony he bought the office of public scribe, and while living by this humble place, devoted his energy to literary creation. Thoroughly accomplished in Greek and Roman literature, he set him-
to himself two great tasks—the naturalisation in Latin of Latin spirit, and the perfect development of the old Roman satire. It is his complete artistic success in both objects which has made him one of the most influential writers of the world, which will secure his name as long as order or culture exist upon the globe.

H.'s first known labours were satires and epodes—the epodes being imitations of the Greek satirist Archilochus. But it is probable that he early began to imitate the other great Greek lyricists; and it is certain that his first success was derived not from the public but the private circulation of his works. He made the friendship of Virgil, whose rise preceded his own, and of Varus; and Virgil and Varus introduced him to Metonza when he was about 26 years old. That great Etruscan noble and friend of Augustus became the good genius of the poet's life. He endowed him—at some period not exactly known, but before 33 B.C.—with a farm near Tivoli, in the Sabine country, established his independence, fostered his fame, sought his intimacy, loved, honoured, and encouraged him as much as one man could and should; and the friendship of Metonza led to that of Augustus, and H. enjoyed all his life (he died at 57) the consideration of the greatest persons of his time. He shews his gratitude for such favour in many passages of his poems, but he is never servile, and he compliments the emperor himself upon those features of his reign which have tended to secure him the gratitude, or, what was not less needed, the forgiveness, of posterity.

It is impossible, in our brief space, to discuss the vexed question of the chronology of H.'s poems, or to notice a fiftieth part of what has been written on it. But if we cannot be sure of the chronology of the poems, they give us themselves ample means for judging of the character of the poet. Even his personal appearance is familiarly known to us. He was a little, round, dark-eyed man, prematurely gray-haired, and inclined to corpulence; in dress somewhat slovenly, and apt to be too full in his gait and manner. He was kindly, friendly, and honourable—irascible, but easily appeased—of amorous and generally sensual temper, yet fully sensible of both the dignity and the proper expression of moderation. His philosophy was Epicurean, like that of most Roman men of the world of his age; but he had both an eye and a heart for the noble in history and in life, and his most discerning readers cannot but see that there was a latent fund of earnestness and even piety in his nature, to which his poetic temper is not wholly alien. The real key to his genius, is to study him as essentially a philosophical wit and moralist, who had an exquisite faculty for lyrical creation, and was a finished artist by diet of the purest examinations for his methods. His writings are philosophically rather than to the poetic class of minds. Some strict modern critics have doubted his being a poet at all, which, since he could produce all the effects of poetry, is plainly nonsense. The latest critics, however, decidedly tend to place his lyrical works—as imitations of the Greek, and echoes of the natural notes of an earlier and more poetich age—farther below his Satires and Epistles than it was once customary to rank them. Meanwhile, this neither robs the Odes of their value, nor of their charm, nor of their merit. Their value, as representing an older literature which only exists in fragments, is immeasurable. Their merit, as breathing now all the gaiety, now all the sadness, of the ancient pagan mind, is irresistible. And their merit, even as imitations, implies a delicacy of insight, a fineness of touch, a power of minute finish, which has been exhibited by no poet before or since, in any other art. They are, indeed, perpetual models of construction, equally valuable to poets of every school, and were not less carefully studied by Wordworth than by Pope. Great, however, as is the merit of the Odes, that of the Satires and Epistles is still higher. The native Roman satire—an indigenous product of Italy, as Casaubon has irrefragably established—was developed by H. into a branch of composition peculiarly his own, and in his own species of which he has never had a rival. He ridicules the follies of the world from the point of view of a man of the world, playing round vice like a picador round a bull; and though his morality does not rise above the level of a prudential maxima, whether of extremes, he endorses this with so much soundness, dramatic liveliness, and gay vivacities humorous wit, that the pulpit has profited by him not less than the pulpit's author's study, and he has been the favourite of ecclesiastical dignitaries and statesmen, while also being the pocket-companion of men of letters and epigrammatists. The Epistles contain the graver element of the Satires in still greater perfection, and with the aid of personal emotion and affection, tinged occasionally with the melancholy of advancing life, which, as the whole, makes them the most valuable of H.'s works.

The literature of H. in modern Europe is copious, and can only be glanced at here in the briefest manner. The Edition Princeps appeared at Milan in 1470, in 4to, and was followed by a long line of editions. In modern times, Orelli has taken a leading place as Horatian editor, and since him, Dillonberger has been justly popular; while England has contributed to the subject, among many other works, the valuable Horatia Reclutata of Tate, and the sumptuous volume of Dean Milman. Among the English translators of H., in the whole or in part, are found Ben Jonson, Milton, Atterbury, Pope, Warren Hastings, and Cowper, while Pope's Imitations occupy a distinc-
tion among the few Masters in the English language. His translations are, in general, as accurate as modern scholarship will admit. His only inferiority is in the translation of the whole of H. in English, is that of Francis, but his day is fast going by. Excellent translations have been issued in our own time by Mr. Coleridge, Mr. Wordsworth, Lord Beaconsfield, and Lord Ravensworth; and a curious one, showing much power, by Professor Newman, whose theory of
HORDEUM. See Barley.

HOREB. See Sinal.

HOREBOUND (Marrubium), a genus of plants of the natural order Labiate, having a tubular 10-rilled calyx, with 5 or 10 spiny equal teeth, 4 stamens included in the corolla, the upper lip of the corolla erect, the lower lip 3-cleft. The species are mostly perennial, herbaceous plants, natives of the south of Europe and the East. One species, the Common or White H. (M. vulgare), is a native of Britain, and is found generally throughout Europe, except in the more northern regions, growing in waste places, waysides, &c. It is about 1-1½ feet high, bushy, with roundish, ovate, crenate, wrinkled leaves, and almost globose whorls of white flowers. The whole plant has a whitish appearance, from the down with which its leaves are covered. It has an aromatic but not very agreeable smell. It is tonic, stimulant, and laxative, and is much used in coughs, being a popular remedy, and a very safe and efficacious one. It was formerly also employed in affections of the womb and of the liver. It is administered in the form of an infusion, or made into a syrup with sugar, and sometimes the syrup is candied. The name H. belongs also to another plant, a native of Britain, Baitola nigra, sometimes called Black H., a fetid plant, also of the order Labiate, and of a genus very closely allied to Marrubium. It closely resembles the White H. in taste, and possesses similar medicinal properties. A third British plant, Lycoptes Europaeus, a diandrous plant of the same natural order, is sometimes called Water Horehound. It is also known as Upsy-wort.

HORIZON, the circular line formed by the apparent meeting of the earth and sky; this, in astronomical phrase, is called the sensible horizon. The rational horizon is the circle formed by a plane passing through the centre of the earth, parallel to the sensible horizon, and produced to meet the heaven.

HORN, CAPE. See Cape Horn, or HORN.

HORN, a musical instrument, commonly called in this country the French Horn; in Italy, Corna; in France, Cor de Chasse. Its form is that of a long tube of brass, with a large bell-shaped end. For greater convenience the tube is coiled up into four continuous circles, lying side by side, the coils being soldered together, to keep them in their position. It is sounded by means of a mouth-piece, in form like a little hollow cup. The thinner the sheet-brass is, of which the horn is made, the more easily can the sound be produced. The sounds obtained on the horn are the harmonics of the sound of its whole length, a fundamental sound which cannot be produced by the mouth. As those sounds form only a limited scale, the notes awaiting are artificially made, by the hand being inserted into the bell, so as to flatten a higher note down to a lower one. These flattened notes are called stuffed notes, as the sound of them is muffled. The horn, in its natural state, can only be played in one key; but by means of crooks, which are added to increase the length of the tube, it can be transposed into any key. When at its greatest length, the horn measures, from the mouth-piece to the end of the bell, 16 feet. The music for the horn is always written in the key of C, with the key of the composition marked at the beginning of each movement; thus, Corno in D, &c., guides the performer as to the crooks he must use, in order to play the notes in the key indicated. The stuffed notes on the horn being very defective in quality of sound, in comparison with the great beauty of the open notes, many inventions have been, from time to time, tried to remedy them. The most successful invention is the valve-horn, which is constructed so that the performer can, by means of three valves, lengthen or shorten the tube, so as to produce any note in the chromatic scale, as a harmonic of the length of the tube, and consequently all of the notes are of the same quality of sound, and open notes. The valve-horn is now generally used as a solo instrument with greater effect than the common horn. As an orchestral instrument, the horn is of great importance. There are never less than two horns in an instrumental score, and in many great works four horns are absolutely necessary. The date of the invention of the horn is lost in antiquity.

HORN MANUFACTURES. The horns of various animals are employed for useful and ornamental purposes. The principal are those of the ox, buffalo, and two or three species of deer, and of sheep, goats. Horn can be softened and split into thin laminae, or pressed into moulds; and as it recovers its peculiar character of flexibility, toughness, and transparency, when cold, it is particularly adapted for a great variety of purposes. It can also be dyed.

Horehound (Marrubium vulgare).

French Horn.
various colours. Solution of gold in aqua regia, dyes it red; solution of nitrate of silver in nitric acid, black; a paste of red-lead, made with a solution of potash, colours it brown; so that, with a proper arrangement and application of these materials, the most admirable imitations of the much more costly tortoise-shell can be produced. The more common vegetable dye-stuffs, as logwood, Brazil-wood, barkwood, saffron, indigo, &c. will also colour it, but neither so permanently nor so brightly as the metallic materials. By long-continued soaking, the horns of all the animals above mentioned, except the deer, can be softened, and those of the sheep and goat can be easily split into several layers when they have been soaked between smooth iron plates heated and placed in a press, but if the edges of two or more are brought together between polished surfaces these will cleave together with a hand-vice, and plunged for some time in boiling water, and thence into cold water, the edges will be found firmly welded together, and the same property enables the horn-worker to use up the smallest cuttings with profit. Another valuable property of horn is, that when heated it can be pressed into a die, and not only takes a beautifully sharp impression, but if left in the die until cold, it retains it. In this way, then, it is employed in making handles for umbrellas, knives, forks, &c., and even ornamental boxes, and a variety of other articles. Combs are made out of the flattened sheets, and beautiful carvings are made out of the solid parts of the buffalo-horns brought in such vast numbers from the East Indies. Ox-horns, too, are sometimes of fine quality and colour, and are fashioned into drinking-cups, and other articles, often highly ornamental. Deer-horns, which, strictly speaking, are bone, have a very limited application; they are employed in this country for making knife-handles, called buck-horn, in much favour for pocket-knives; but on the continent the horns of the fallow-deer are extensively used in making the deer-horn articles of furniture peculiar to Germany. The deer-horns used in Great Britain are chiefly those of the Axis (Axis maculata), of which at least 100,000 are annually imported from the East Indies. From the same country are brought to Britain 800 tons of buffalo-horns, whilst from South America and other parts, the importation of ox and cow horns exceeds a million annually.

HORN-WORK, in Fortification, is a work having one front only, thrown out beyond the glacis of a fortress; with a view, 1. To strengthen a weak salient in the general outline; 2. To occupy a plateau in advance of the place, or to protect buildings, the including of which in the original enceinte would have extended it to an inconvenient degree; 3. To occupy a tongue of land protected on its sides; 4. To bar a defile; 5. To cover the head of a bridge; 6. To occupy rising ground, the possession of which would render the enemy more than necessarily dangerous. The front of a horn-work consists of two demi-bastions connected by a curtain, and usually defended in front, as in the fortress itself, by tenaille, ravelin, and covert-way. The flanks, protected by ditches, run straight upon the ravelin, bastion, or curtain of the main defences, so that the enemy may be swept by the fire of the latter. The flanks should not be too long for easy musketry range.

In most of the earlier works of this nature, the ditch of the horn-work was united with the ditch of the main works by being cut through the glacis and covert-way; but in modern works the horn-work is constructed entirely beyond the glacis, as the annexed figure shews. The masonry wall is shewn in the figure by a thick black line at the head of the horn-work and immediately beyond the glacis, but at times it is merely a straight wall thrown across, as in the dotted line. Occasionally, horn-works are very useful; but modern engineers generally prefer constructing detached and advanced works. A double horn-work becomes a Crown-work (q.v.).

HORNBEAM (Carpinus), a genus of the natural order Cupuliferae; consisting of trees with compact, tough, hard wood; bark almost smooth and of a whitish-grey colour, deciduous leaves, and monocious flowers. The male catkins are cylindrical and sessile, their flowers consist merely of a little scale-like bract and 12—24 stamens. The female flowers consist of a germen, crowned with the 4—8-toothed border of the perianth, and with two thread-like stigmas, and are placed in loose slender catkins, always two together, each at the base of a staked bract, which is three-cleft or three-cornered, and
HORNBILL—HORNET.

which, when the tree is in fruit, enlarges very much, becomes leafy, and covers the fully ripened nut on one side. The nut has a thick husk, and is small and striated. The Common H. (C. Britius), very frequent in the woods of many parts of Europe, is a beautiful tree, attaining a height of 60—100 feet. It is seldom, indeed, now seen of such dimensions in Britain; but it seems to have formed a principal part of the ancient forests of some parts of the island. It has elongato-ovate, acuminate, almost triplicate leaves. When in fruit, it has very large, deeply 3-parted bracts. It thrives best in a moderately moist and shady situation. Its root descends deep into the ground. The wood is white, very hard, uncommonly strong and tough, and therefore suitable for bearing heavy strains. It is much used by joiners, turners, and wheelwrights. It takes a very fine polish, and, when well stained, might readily be mistaken for ebony. In the earth, or where exposed to the changes of the weather, it is of no great durability. It burns like a candle, and it is one of the best kinds of firewood; it affords an excellent charcoal, and the ashes yield much potash. The young stems, by reason of the dense growth of their twigs, are very suitable for forming live-fences and bowers; and as it bears clipping very well, the H. was often employed to form those live-walls which were formerly so much the fashion in gardens.

HORBILL, the name of a genus (Bucerot) and of a family (Bucerotidse) of birds, to which Cuvier assigned a place in the syndactylous division of the order Inaeororir, but which some naturalists rank with crows in the tribe Corvistrea. Their anatomical structure has been found to indicate affinities both with crows and toucans, and the same inference may be drawn from their habits. The species are numerous; they are natives of Africa and the East Indies. They are mostly large birds, some nearly as large as a turkey, the smallest rather smaller than a magpie. They are remarkable for the enormous size of the bill, and for a large bony protuberance with which it is generally surmounted. The bill is curved, broad at the base, compressed towards the tip; the bony protuberance on the upper mandible assumes different forms in different species. They may be described as omnivorous.

HORNBLEND, a mineral allied to Augite (K₂Fe₂Si₈O₂₂(OH)₂), and containing from 40 to 60 per cent. of silicas, with variable quantities of alumina, lime, oxide of iron, soda, potash, and fluorine. H. is found in granite, syenite, and other igneous rocks which contain quartz or free silica. It is particularly abundant as a constituent of syenite. It is sometimes found in considerable masses, and even in beds of slaty structure (H. slate). The variety called Common H. is generally green or black more rarely brown or gray. It contains a pretty large proportion of protoxide of iron; is generally massive, but sometimes crystallises in oblique four-sided, or in six-sided prisms. The crystallised H. is sometimes called Black Schorl, and is capable of being made into ornaments.

HORNCASTLE, a market-town of England, in the county of Lincoln, is situated in an agreeable district at the foot of the Wolds, 20 miles east of Lincoln. The parish church is the most interesting of the public buildings; portions of it were erected during the reign of Henry VII. There is a considerable trade here in corn and wool; and of the three annual fairs, that held in August lasts for ten days, and is one of the largest horse-fairs in Britain. There are at H. remains of a Roman fortification; coins and other antiquities are occasionally found in the neighbourhood. Pop. (1861) 4846.

HORNE, REV. THOMAS HARTWELL, D.D., an English biblical critic, born October 20, 1786, was educated at Christ's Hospital, and afterwards became clerk to a barrister. His leisure hours were devoted to the study of the Bible; and in 1818 he published his Introduction to the Critical Study and Knowledge of the Holy Scriptures, a work which procured for him admission into orders without the usual preliminaries. Subsequently, St John's College, Cambridge, granted him the degree of D.D., and two American colleges that of D. D. In 1833, he obtained the rectory of St Edmund the King and St Nicholas Acon, London. He was also made a prebendary of St Paul's Cathedral. In the course of a long life, H. has published a great variety of works, but the one already mentioned is the principal. From the first moment of its appearance, it not only became popular, but attained the dignity of being considered the text-book on the subject in all or almost all the theological colleges of Great Britain and America. It has gone through ten or eleven editions, and has been frequently improved, so that it still retains the high reputation which it originally bore.

HORNET (Vespa crabro), the largest species of wasp found in Britain. It is not uncommon in some parts of England, but is not found in Scotland. The thorax is mostly black, the fore-part murius; the abdomen is yellow, with three brown points
HORNING.—Horny Tissues.

Each segment. The sting is very painful. The H. is a voracious insect, seizing and devouring bees and other insects, and carrying them to its nest to feed its young. The nest is in a hollow tree, in an outhouse, or in some other sheltered place.

The community is not supposed ever to contain more than about 200 individuals, all deriving their origin from a single female, which, having survived the winter in some sheltered hiding-place, lays the foundation of the nest in spring. The nest is a cup-shaped mass, of a substance resembling coarse paper, and, except as to size, very similar to that of the common wasp. The community consists of females, males, and neuters or workers, as in the case of bees, but there are numerous females. Most of the males and neuters perish on the approach of winter, some of the females alone surviving.

HORNING, LETTERS OR, a writ in Scotch Law, which issues to compel a party to execute or carry out a judgment or decree of the court. The writ was formerly the only form of enforcing civil decrees by imprisonment, except in the case of small-debt decrees. But by recent improvements, the process is shortened, and other forms are more used.

HORNITOS, or HORNOS (Span. ovens), the name given to the low oven-shaped hillocks which emit smoke and vapours, and which occur in great numbers on the sides and in the neighbourhood of the large volcanoes of South America.

HORPIPE, a musical instrument, consisting of the common wooden pipe with the necessary holes for producing the notes, and with a horn on each end. The performer blows into one of the horns, and the sounds of the pipe proceed out of the other. In the north-west of England, where this instrument is mostly found, it is used to accompany a national dance which is also called the Hornpipe. The melody of this dance is always in triple time—that is, in 3/4, or 3/8, and sometimes in 1/4 time—and it consists of two parts of four or eight bars each, with repeats. The movement of the dance is tolerably quick.

HORNS are appendages to the frontal bones of many of the extensive family of ruminants, and are obviously intended as weapons of defence. In the genus Cerus (deer), the horns (known also as antlers) are solid, uncovered by epidermis, bone-like in composition, and decumbous. In the genus Camelopardalis (the giraffe), we have the single example of solid persistent horns completely invested with a hairy integument. In the other horn-bearing ruminants,—as the ox, sheep, goat, and antelope,—the horns are hollow, uncovered by epidermis, and composed of a special tissue (Horny Tissues, q.v.) quite different from bone, and are persistent. In all these cases, the horns are attached to the cranial bones; and in all the hollow horns, except those of the antelope, the osseous axis is hollowed out into cells communicating with the frontal sinuses, and thus admitting the atmospheric air into the interior. The horn of the rhinoceros is quite distinct in character from the horns of the ruminants. It is a tegumentary, not an osseous appendage, and is usually described as if it were a mass of hairs which had coalesced. It consists, however, in reality, of an aggregation of tubercles, from which the horny matter is arranged in concentric lamines, as in the horny excrescences on the inner surface of the leg of the horse. The first and the third variety,—viz., the antlers of the Ceridex and the hollow horns of the ox,—alone require special notice.

The deciduous horns of the Ceridex at different ages, and their process of growth, are explained in the article Deer. To that description, it need only be added, that those horns are formed on two well-marked morphological types—one group possessing rounded antlers, such as occur in the red-deer and the red-deer, and the other having the antlers more or less flattened, as in the elk and fallow-deer. A remarkable sympathy exists between the generative organs and the horns; and the development of the latter may be arrested, and their peripodial shedding may be prevented by castration. As a general rule, it is only in the male Ceridex that horns are developed. In the reindeer, however, they are common both to the male and female.

In the hollow-horned ruminants, the bony prolongations or 'cores' arising from the frontal bones, and supporting the horns, instead of branching like antlers, form more or less solid cylindrical shafts, the surface being protected by ordinary Periosteum (q.v.), and by an extension of true skin, which becomes keratinized and is shed; in the accompanying figure, the horns sheath is detached from the right horn, so as to show the 'core' in the interior.

The horns of ruminants are almost invariably two in number, but exceptions occur in the case of the extinct Bramatherium and Sivatherium, and amongst living species, in the Four-horned Goat, the Many-horned Sheep, &c. In the Pronghorn Antelope there seems to be an approach to the cervine type, there being a prong of some length half way up the horn, which may be regarded as analogous to the brow-antler.

Horny Tissues were formerly regarded as extremely simple in their structure, and as being only different forms of a substance to which the term keratin (from Kerux, a horn) was applied. Recent investigations, however, show that the parts which consist of horny tissue—e.g., for example, the persistent horns of the ruminants, the epidermis, the nails, claws, and hoofs, whalebone, tortoise-shell, &c.—have a somewhat complicated, and, in some respects, a variable structure, although they are so far analogous to one another that they proceed from nucleated cells which are not morphologically developed like the cells of most other organs, but which, to a certain extent, dry up and are only agglutinated together by an intercellular substance; taking this point of view, they are closely resemble one another, for when compared with other tissues they all contain a large quantity of sulphur, in combination with a substance whose origin from, or affinity with the Proteine Bodies (q.v.), is sufficiently obvious from their behaviour towards certain re-agents (the caustic alkalies and the mineral and acetic acids, for example), and their percentage composition.

The accompanying figure represents a longitudinal section of cow's horn (magnified 410 diameters) taken perpendicularly to the surface, kept for four hours in concentrated potash solution, w
HORNY TISSUES—HOROLOGY.

which water was then added. If, however, a section of horn is examined in its natural state, it appears to consist of numerous bundles of fine threads lying side by side. After the addition of the potash solution, these bundles are seen to unfold into little plates, which gradually expand into the regular nucleated cells shown in the figure.

The cellular structure of hoofs, whalebone, tortoise-shell, &c., may be exhibited in a similar manner. It is to the histo-chemical investigations of Muhlner and Donderers that we are mainly indebted for our knowledge of the structure of these tissues, who seem to have established that every horny tissue contains at least three different kinds of substances—viz., 1. The keratin or the cell-membranes, which is exceedingly difficult of solution in alkalies, and which forms the principal part of the tissue; 2. The cell-contents, which dissolve more readily in alkalies; and 3. A cementing or true inorganic substance.

These tissues have been submitted to ultimate analysis, after having been previously digested in water, alcohol, and ether. The analoguy of their composition is shown in the following tabular view:

These tissues differ slightly in the quantity of inorganic matter which they contain, but the difference does not vary much beyond 1 per cent.

Hair yields from 0.94 to 1.35 per cent of ash, containing, amongst other ingredients, peroxide of iron and a little silica. In feathers, the quantity of silica is very considerable, and it is doubtless to this constituent that the shaft in a great measure owes its strength and hardness.

HOROLOGY (Gr. ὁρόν, a defined portion of time, that has for its object the measurement of time. Although it is easy to look back on a period when time, according to the modern conception of it, as measured by hours, and minutes, and seconds, was unknown, yet we find progress early made in the measurement of larger periods of time, by observations of the heavenly bodies; and although, in the later progress of astronomy, it is found that the movements of the more conspicuous heavenly bodies do not afford accurate marks for the equable measurement of time, they were, for practical objects, sufficient, and afforded at least a better measure of time than any other phenomenon which came under the observation of mankind. Thus, time was early divided into years, according to the motion of the sun among the constellations; into months, according to the motion of the moon relatively to the sun's place in the heavens; and into days, by the alternate light and darkness caused by the rising and setting of the sun.

It was long, however, before any accurate measure was found for a division of the day itself. The earliest measure employed for this purpose that we can trace is the shadow of an upright object, which gave a rough bundle of time by the variations in its length and position. This easily suggested the invention of Sun-dials (q. v.). Another means early adopted for the measurement of short periods of time was by the quantity of water discharged by dropping from one vessel into another. Instruments for the measurement of time on this principle were called Clepsydras (q. v.). The running of fine sand from one vessel into another was found to afford a still more certain measure, and hence the invention of hour-glasses (q. v.). King Alfred is said to have observed the lapse of time by noting the gradual shortening of a lighted candle. It is not very easy to trace to its source the history of the invention to which the modern clock owes its parentage; the earliest, however, of which we have a complete description, and perhaps the earliest which attained any distinct superiority to the rude machines already mentioned, was the clock of Henry Vic or De Wyck, a German, erected in the tower of the palace of Charles V., king of France, in 1579. A sketch of this clock, which is subjoined, will be useful not only from its historical interest, but also because, from its comparative simplicity, it will form a groundwork for further explanation of the mechanism of clocks and watches in their more complicated forms. It will be readily understood, from a glance at the annexed figure, that as the weight A tends to uncoil the cord and set in motion the cylinder B round its axis, the motion will be successively communicated to the various toothed wheels in the figure, and finally to the crown-wheel or escapement-wheel, I; the teeth of which so act on the two small levers or pallets, i, h, projecting from, and forming part of the suspended upright spindle or vertical axis, KM, on which is fixed the regulator or balance, LL, that an alternating or vibratory, instead of a continuous, motion of the balance itself is the result. The hands of the clock are attached to the wheel N, also set in motion by the cylinder B. Now, unless there were some check upon the motion, it is manifest that the heavy weight A would go rapidly to the ground, causing the wheels to rotate, the balance to vibrate, and the hands to go round with increasing velocity. In order to prevent this rapid unwinding of the clock-work, and adjust it to the more deliberate measurement of time, the balance is, in De Wyck's clock, loaded with two weights, m, m; and the further these are removed from the axis or spindle, KM, the more heavily they will resist and counteract the escapement of the levers, and the rapidity of the rotation of the escapement-wheel, till the clock be brought to go neither too quick nor too slow.

The above construction is probably the basis of all the principal time-keeping machines in use in the 16th century. The great epoch in the history of horology is marked by the application to it of the Pendulum (q. v.) as a regulating power. This was effected by Huygens (q. v.) about 1657. This philosopher, in adapting the pendulum to the machinery previously invented, had little more to
HOROLOGY.

The principle of construction adopted by Huygens, from the peculiar action of the lever and spindled, required a light pendulum and very small arcs of oscillation in these large areas, the ingenious device of constraining the motion in a cycloidal curve was resorted to; yet the consequence was, as has been remarked, that 'Huygens's clock governed the pendulum, whereas the pendulum ought to govern the clock.' About ten years afterwards, the celebrated Dr. Hook invented an escapement, which enabled a less maintaining power to carry a heavier pendulum. The pendulum, too, making smaller arcs of vibration, was less resisted by the air, and therefore performed its motion with greater regularity. This device is called the 'crutch or anchor escapement.' It was brought by Hook before the notice of the Royal Society in 1678, and was practically introduced into the art of clock making by Clement, a London clockmaker, in 1880. It is the form still most usually employed in ordinary clocks. It regulates the motion as follows: The pendulum is fixed at A, and hangs down behind the pallet-wheel, the last of the train of wheel-work, which revolves in the direction of B; under the action of the weight, B and C are the pallets. When the pendulum swings to the left, AC raises, and a tooth escapes from C, while another falls on the outside of B, and, owing to the form of the pallet B, this latter recoil during the remainder of the swing. The same thing occurs on the pendulum's return; the arm AB rises, a tooth escapes from B, and another falls on the inside of C, and is pushed backwards by it during the remainder of the swing. The revolution of D is thus regularly retarded, one tooth being allowed to escape for every two oscillations — i.e., every two seconds — and as the wheel contains 30 teeth, it performs one revolution per minute (the seconds hand is fixed on the extremity of the axle of this wheel). During a portion of each contact between the pallets and teeth, the outward pressure of the wheel gives an additional impetus to the pendulum, so as to counteract the retarding effects of the resistance of the air and friction, which would otherwise bring it to a stand.

The only defect of this escapement is the recoil, and various modifications have been devised to obviate this. The first and most successful was made by George Graham, an English watchmaker, in the beginning of the 18th c., and his improved form is called the 'dead beat escapement' (fig. 3). Here the outer surface of B and inner of C are arcs of circles, whose centres are A, and a little consideration will shew that there can be no recoil. This escapement is adopted in time-keepers when great accuracy is required. Other inventions, as the detached escapement, the pin-wheel escapement in various forms, and the gravity escapement (described below), though very efficient, have not come into general use.

In the great clock in the new Houses of Parliament, the pendulum is of iron, 8 feet long, it takes 2 seconds, and its bob weighs 6 cwt. The motion is kept up by a remontoire or gravity escapement. On each side of the pendulum a small metallic hammer is hung upon a peg, which is initiated by a little bolt, that stopped the turning of a wheel; the wheel then goes round, under the influence of the weight, lifting one of the little hammers as it does so, until it is caught by another bolt. The hammer-head next falls by its own weight, and the pendulumrod just as it is in the act of descending, communicating the force of its blow to quakes the movement; the same thing is afterwards repeated on the opposite side of the vibration, and then again on the same side; so going on alternately. The push thus given is evidently unvarying. The wheel has three stops and cogs on it, and goes once round in three beats of the pendulum, or 6 seconds. It is provided with an adjustment that all the teeth of the several wheels may be rough, just as turned out from the casting, and the clock will nevertheless keep better time than it would have done with the most perfectly finished teeth under other circumstances.

The gradual perfection of the clock required also improvements in the pendulum. No simple pendulum, however, can be depended on for an accurate timekeeper, for the isochronism of vibration of the pendulum, i.e., the time of one swing, depends on the same length; now a cord contracts or expands with changes in the moisture of the atmosphere, and a rod with cold or heat. To overcome these defects in the pendulum, compensating pendulums were invented, of which Gower, Harrisons's gridiron pendulum, invented in 1718, and Harrisons's compensating pendulum, invented in 1726, are the two principal forms (see Pendulum).

The above improvements in the escapement and the pendulum bring the mechanical perfection of the clock, as a time-keeping instrument, to the point which it has attained at the present day. But the art of horology would be incomplete unless there were some standard, independent of individual mechanical contrivances, to which all may be referred, and by which the errors of each — which must exist in the most perfect human contrivances — may be corrected. The movements of the heavenly bodies are still, as of old, the only standard for a general measurement of time, affording as they do marks of unvarying certainty, to be read by all alike; and clocks and other mechanical contrivances are individual and imperfect measures of the intervals, to be trusted only until there is a new opportunity of comparing them with the certain and public signals of the heavens. These signals can, however, only be accurately read by persons furnished with the proper apparatus, and instructed sufficiently in its use.

This is done in observatories, and there are in most parts of this country now sufficient opportunities of setting clocks by a communication more or less direct with these establishments. When these clocks are to be had, the sun-dial may still be used with advantage, as a means of approximation to the correct time. The time which a clock ought to mark is mean time, the definition of which will be found in the article Day (q.v.). The mean time at any place depends on the longitude. Supposing a clock to be set to Greenwich mean time a clock keeping mean time of any place will be 15 minutes faster for every degree of longitude east of Greenwich.
HOROSCOPE—HORSE.

15 minutes slower for every degree west. Since the introduction of railways, clocks are usually set, within Great Britain, to Greenwich mean time.

The methods by which time is determined in observatories belong to the details of practical astronomy. For the more ready transmission of correct time to the public, there is at Greenwich Observatory, as well as some others, a ball which is dropped by means of electricity precisely at one o'clock. Within the last year or two, however (1860—1861), there has been invented a more ingenious device by which public clocks in a town can be kept at every instant in perfect agreement with the mean-time clock in the Observatory. This is effected by an electric connection, and a modification of Bain's electric pendulum, invented by Mr R. L. Jones of Chester, on the suggestion of Mr Hartnup, the Astronomer of the Liverpool Observatory. For a description, see Electric Clock. The first public application of it was to the town-hall clock in Liverpool, when for the first time was seen the curious spectacle of a great clock with works nearly 100 years old keeping time with astronomical accuracy. In the same way, a clock in the castle of Edinburgh, by whose mechanism a gun is fired precisely at one o'clock every day, is controlled by the mean-time clock in the Observatory on the Calton Hill. To such perfection has the art of publication, as well as the keeping of correct time, been now brought.

It is not known when the alarm, or when the striking-mechanism of the clock was first applied. The alarm was adopted for the use of the priesthood, to arouse them to their morning devotions. The first striking-clock probably announced the hour by a single blow, as they still do, to avoid noise in churches. In De Wyck's clock, the wheel N, with its projecting pins, served to discharge the striking part (not represented in the figure). During the 17th c., there existed a great taste for striking-clocks, and hence a great variety of them. Several of Tempion's clocks not only struck the quarters on eight bells, but also the hour after.

at stated periods in course of the workings of the time-keeping apparatus—viz., at the completion of every hour; when the minute-wheel, which revolves once in an hour, and carries the minute-hand of the clock along with it, brings it into action by the temporary release of a catch or detent, permitting the weight wound up on the cylinder of the striking-apparatus to run down for a little, in doing which, the hammer is forced into action, so as to strike the bell. Whether the strokes shall be one or many, is determined principally by two pieces of mechanism, one called a small, from its form or outline, with twelve steps, and the other a rack, with twelve teeth; but the intricate action of the whole it would be in vain here to attempt to explain. Suffice it to say, that the time during which the striking-weight is allowed to descend, varies according to the turning of the twelve steps of the small on its axis, and the position of the twelve teeth of the rack, at different hours of the day; being sometimes only long enough to permit one blow to be given by the hammer on the bell, and at another time long enough for twelve such blows.

The consideration of portable time-keepers (watches and chronometers) is reserved for the head WATCHES.

HOROSCOPE. See Astrology.

HORS DE COMBAT. A French term, literally meaning 'beyond the battle,' is used to signify a combatant, or body of combatants, so completely beaten either by physical force or strategy, as to be incapable of further action in the struggle actually under consideration.

HORSE (Equus), a genus of pachydermatous quadrupeds of the family Equidae (v. q.v.), or Suidae, generally included as a subfamily of the family, although sometimes limited (see Ass), so as to contain only one species, the most important to man of all animals that are used as beasts of burden and of draught. The principal zoological characters are already given in the articles Equus and Ass, and a more particular description of the H. seems to be unnecessary. The native country of the H. is uncertain. Some contend for Asia, and some for Africa; some suppose that the H. was first domesticated in Egypt, and quote Scripture in support of their opinion, but to no better purpose than to show that at a very early period it was in use as a domesticated and valued animal among the ancient Egyptians; whilst others advance arguments not more conclusive to show that it was originally domesticated in the north-east of Asia; some think it not improbable that Europe also, and even Britain, had indigenous horses. Whether certain wild races of Central Asia and the north of Africa are really indigenous to the regions in which they are found, or the offspring of animals which have escaped from domestication, like those of America; and whether the origin of the domestic H. is to be referred to one original form, or to several forms somewhat different, and belonging to different countries, are questions also uncertain; and the least of them is very similar to that which moves the time-measuring mechanism itself; but the pressure of this weight on the striking-machinery is only permitted to come into play.

Fig. 4.—Horologe:
Presented by Henry VIII. to Anne Boleyn.

each quarter; at twelve o'clock, 44 blows were struck; and between twelve and one, no less than 113! Many struck the hour twice, like that of St Clement Danes, in the Strand, London, first on a large bell, and then on a small one. Others, again, were invented so as to tell the hours with the least possible noise; also by the aid of two bells, each blow on the small one indicating five hours.

The striking part of a clock is rather a peculiar and intricate piece of mechanism. In ordinary clocks, the impelling power is a weight similar to that which moves the time-measuring mechanism itself; but the pressure of this weight on the striking-machinery is only permitted to come into play.

298

The lips and teeth of the H. adapt it for cropping the short herbage of dry plains or hills, so that it finds abundance where an ox would be very insufficiently supplied. The feet are also adapted to dry rather than to soft or swampy ground. On soft ground, not only is the foot apt to sink, not being very broad, but the horny hoof is softened, and a diseased state of the feet is the result, in the case of many of the great dray-horses of London,
Horse

reared in the alluvial districts of the east of England. The H., however, requires a liberal supply of water; and during the dry season, in the hot plains of South America, great troops of wild horses often rush furiously to the rivers, and as they approach the drinking-place, trample one another under foot, vast numbers of skeletons remaining to bleach in the sun.

Wild horses are found on the plains of Central Asia. Some also inhabit mountainous or hilly districts both there and in the north of Africa. They abound still more in the grassy plains of South America, although they were first introduced into America by Europeans; and certain tribes of Indians, both in North and South America, have become, at least as equals, in many ways seem as any of the Tartars of the east. Wild horses are also found in the Falkland Islands, into which they were introduced by Europeans, and a peculiar breed has been found in a wild state in the island of Celebes.

The races or varieties of the H. have an evident relation to the climate of the countries in which they occur. Those of cold and stormy regions are comparatively small and rough-haired; those of more favoured climates, large and sleek. There are also differences among those evidently to be ascribed to domestication, according to which certain breeds are particularly adapted to certain kinds of work, some excelling in fleetness, some in endurance, some in mere strength for burden or draught. The smaller forms of the race-horse, one of the commonest, seems almost as strongly with the ponderous solidity of the dray-horse, as the great size of the latter does with the diminutiveness of the Shetland pony.

Wild horses congregated in troops, sometimes small, but sometimes of many hundreds. The males have fierce countenances, and males that have contended unsuccessfully are often driven off to a solitary life. On the appearance of danger, they raise themselves on their hind-feet, and bring down the force, with great force on the enemy, of wheeling about, and striking back and forth, with the back, and black mane and tail. The eye is small and vicious. Tarpans are sometimes caught by the Tartars, but are with great difficulty reduced to subjection. In some of the steppes of Central Asia are wild horses of a white or dappled-grey colour. —The wild horse of South America is there called the Mustang. It exhibits considerable diversity of colour, but bay-brown is the most prevalent. It is strong and active, and is often taken with the lasso, and employs the service of the Indians, and in its pursuit. A curious method is practised by some Indian tribes of promptly subduing its wild nature, and rendering it tractable, by blowing strongly with the mouth into its nostrils. By other tribes, it is subdued more readily, when it is seen on the ground; but if it can recover, a man gets upon its back, whom, when it rises, it cannot shake off, and who retains his seat until it is quite submissive. —The Koomrah of North Africa is regarded by Colonel Hamilton Smith as a distinct species (H. kiyogruus). It has no forelock, but woolly hair on the forehead, is of a reddish bay colour without stripe on the back, or any white about the limbs, has limbs of a somewhat asile shape, and the tail covered with short hair for several inches at the root. It is an inhabitant of mountainous regions.

Of domestic varieties and breeds of the H., the number is very great, almost every country or considerable district having one or more of its own, and particular breeds being valued on account of their fitness for particular purposes. The breeds are also continually varied by crossing, and great improvements have thus been effected. The superior breed of the English of Norlanc and F.Lanc. is probably the Hunter, are ascribed to the crossing of the old English breed of light-limbed H. with the Arabian; and the English dray-horse, remarkable for its great strength and stamina, is almost certainly the result of the crossing of English draught-horses with the Flemish. A breed produced by crossing one of the lighter kinds of English draught-horse with the race-horse, is in the highest esteem for carriage-horses. North America has a breed of light-limbed horses, remarkable for fast trotting. The Suffolk Punch has been the origin of many of the most useful kinds of draught-horses employed in Britain for ordinary farm-work. The Oudh Arab, employed in the Oudh Horse service, is an old breed of the class, and is an improvement on an older breed. Numerous breeds of smaller size, ponies, have long existed in different parts of Britain, and in almost all other countries. The Shetland Pong, which, crossing with the dray-horse, is little esteemed in any edition of a book beside a great folio, is most prized when most diminutive, and sometimes does not much exceed a large dog in stature. A strong man has been seen to lift one of his arm, and upon it ride on its back, whilst at the same time he walked with his feet on each side on the ground. The Shetland pony is, however, a very handy animal, and remarkably strong.

The Arabian has long been the object of untiring care and attention, and to this very much of the excellence of the race is certainly to be ascribed. The regard of the Arab for his horse has long been famous. Very similar in some respects to the Arabian is the Barb, which, highly valued and esteemed in the West, is not exactly the same breed, being of a smaller size, but equally strong. The Barb has been extensively improved by crossing, and the breed has been much affected by the introduction of a foreign strain. The Barb is a most valuable race-horse, and is the type of all fine horse breeds, and is employed in every part of the world for all purposes. The Barb is a most valuable race-horse, and is the type of all fine horse breeds, and is employed in every part of the world for all purposes.
HORSE.

A horse has been seen to procure a supply of apples
in an orchard by throwing himself forcibly against
the trees and shaking them.

The flesh of the horse is used as food in some
countries. Its use has recently found advocates in
France and some other parts of Europe. It is sold
in London as food for dogs and cats. Mares' milk is
much used by some of the tribes whose chief wealth
consists in horses, and the horses of all ancestors of
it to fermentation, and distil from it a kind of spirit.
The hide of horses is made into leather, which is
used for covering large office and board-room
tables, &c. The long hair of the mane and tail is
used for making haircloth, stuffing mattresses, &c.

Hybrids between the H. and the ass are noticed in
the articles HINNY and MULE. Hybrids have
also been produced between the H. and the zebra,
and between the H. and the quagga, exhibiting, in
some degree, the stripes so characteristic of these
species; but they have been turned to no use.

Fossil Horse.—The remains of the horse have been
long noticed associated with the mammoth, rhino-
ceros, and other extinct quadrupeds, in the old
formations and ossiferous caverns in the New World,
as well as in the Old. Their occurrence in America
is the more remarkable, from that continent being
entirely without the horse when it was discovered
by Columbus. Horses are not generally a valuable
species in the fragmentary is known. The largest
(Equus fossnfa) was about the height of a
middle-sized domestic horse, and differed from
this animal in possessing a proportionally larger
head and jaw. It resembles in this respect the wild
horse of Asia described by Pallas, and in
having the molar teeth, while equal in length, yet
decidedly smaller. The second species (Equus
pickensia) was about the size of a large ass, and
differed from the other species, as well as from the
living horse, in the more complex incisions of the
enamel of its molar teeth.

Horses, of whatever breed or description, should
be of good size, shape, and style; for superior animals
are fed and kept at the same cost as inferior sorts; are
always able to perform their work easily and
satisfactorily, and are at any time saleable at remuner-
ative prices. To produce such animals, requires
careful selection of breed, active, symmetrical
descendants, and the mare carried a colt eleven
months, but occasionally exceeds her time by one or
two weeks. Farmers prefer their mares to foal in
May, from which time the age is generally calcu-
lated, but on the turf, ages date from January, and
hence the earlier the racing foals are dropped the
better. Parturition is usually performed easily and
without any assistance, the foal soon getting on his
legs, and suckling. Good grass, with a feed of oats
daily, will insure an abundant supply of milk.
Weaning may take place in five or six months; and
the foal, when taken from its mother, must be supplied
with a few oats and bran, some good hay, and
comfortable shelter at night. At 1 year old, colts
and mares are turned out to pasture, and are given loose
hay and lightly worked about three years old; but,
derunder good treatment, they continue to grow, and
ought not to be put to severe work until they are
2 years of age.

Oats and hay are the staple articles of food for
hard-working horses. The oats should be sound,
tweet, and heavy; and for hacks and hunters, are
sufficiently dry until they are a year old. Absence
of green grass or vegetation is unbearable. To
insure thorough mastication and digestion, oats
should be given either slightly bruised, or along
with some chaff. For coaching or farm-work, a few
beans or pease should be given; half a bushel, along
with a bushel of oats and hay, is a usual weekly
allowance for log-horses. Close and Rye-grass Hay
(q.v.), such as is common throughout
Scotland, is more palatable and nutritious than the
meadow-hay in general use in England. Riding-
horses generally consume daily about 3 bushels
and a half of hay, and consume daily
14 pounds of hay; but the heavier class of
horses require more. Farmers use oat, pea, and
bean straw for fodder during the winter months,
and in most well-managed establishments, a consi-
gerable portion of the fodder is now given cut
hay, which enables the hard-worked horse to fill himself
more rapidly, and thus gives him more leisure for
rest and repose. Cart-horses usually have an even-
ing allowance of sliced Swedes or carrots; a daily
pound of linseed-cake is now frequently added, to
keep the coat glossy; whilst a weekly bran-mash is
advisable, and should contain during winter an
ounce of pounded nitre. Horses should be liberally
supplied with water at least three times a day, and
it is very necessary to restrict the supplies, except
for a few hours before severe fast work, and when the
animal is much overheated and fatigued. In some
well-constructed boxes and stables (see STABLES),
there is water continually before the animal, in a
shallow vessel capable of holding about a quart, and
which, as it is removed, is slowly replenished, and
thus cannot be drunk either with undue rapidity or in
injurious quantity. During summer, horses generally
may have such green food as grass, clover, or vetches;
but if their work is severe or long continued, oats
and hay ought still to form the principal articles of
diet. In summer, farm-horses are often turned out
to graze after their day's work is over; but it is
generally more economical to bring their green food
to the stable, or, better still, to commodious yards.
It is seldom advisable to follow the old-fashioned
plan of turning hacks or hunters out to grass, as
they are apt to get kicked or otherwise injured, and
lose besides their condition. If not required during
the summer months, they are better and safer in
a large yard or a commodious box, where they can
have proper feeding and daily exercise. They will
thus, at little extra expense, be kept in good
condition, and fit for work, their legs free from blemishes,
and their constitutions uninjured by violent divers-
ities of feeding and management. The small
mammal feeders of the farm indicate the
necessity of his being fed at frequent
meals, at intervals of five or six hours. In most localities,
farm-horses turn out at seven, returning to the
stable at 11.30 or 12, being fed and rested for an
hour and a half or two hours, and then returning to
work for four or five hours. In the midland and
southern counties of England, the straggling position
of the fields, and their inconvenient distance from
the stables, induce many farmers to keep their
horses in the yoke from seven until two or three,
when they finish for the day. This practice is,
however, by no means commendable, unless the
work is very light, and the horses have a feed, a
few mouthfuls of water, and 10 or 15 minutes' rest
about mid-day.

To insure health, horses must be kept in
commodious, well-lighted, airy, properly-ventilated
stables, which ought to be erected only in dry situa-
tions, should be thoroughly ventilated, and well
paved, if possible without a loft overhead, white-
washed annually, and always kept scrupulously
clean and free from smell. This may be effected by
the prompt removal of soiled or wet litter, and by
shoveling the manure daily with a horse-train
or McDougal's disinfectant powder. Where there is

435
HORSE—HORSEMANSHIP.

room, loose boxes are preferable to stalls, especially for the lighter sort of horses, that spend much of their time indoors. With proper feeding, exercise, and grooming, with plenty of fresh air, and good stable management, horses are scarcely ever out of health, and require neither balls, cordials, nor any such messes. Without professional advice, no groom or master should, under any pretence, be permitted to indulge his predilection for physicating or doctoring healthy horses.

HORSE, a miner's term, applied to any intruded material which is the apparent cause of a sudden interruption in the continuity of a mineral that is being quarried. With vein-miners, a detached mass of rock or spar which fills the vein receives this name, while colliers apply the term to the shale which occupies a natural but sudden thinning out of the coal-bed, as well as to such interruptions as seem to have been the channels of small streams, and which were subsequently filled up by the clay that formed the roof of the coal.

HORSE-CHEESNUT (Aesculus), a genus of trees of the natural order Sapindaceae, having large opposite digitate leaves, flowers with five spreading unequal petals, and a leathery 3-valved capsule covered with soft spines. The seeds, which are not more than three in each fruit, are large, and somewhat resemble chestnuts; but the habit of the trees, their leaves, and their flowers, are very unlike those of chestnuts, with which they have no botanical affinity.—The Common H.: (A. hippocastanum) is a much esteemed ornamental tree, very frequently planted in Britain, and in all parts of Europe of which the climate is suitable, on account of its rich foliage, and its erect racemes of beautiful reddish white flowers, which are produced at the extremities of the branches, and contrast admirably with the dark green of the leaves. At St Petersburg, the H. is a greenhouse tree. It is supposed to be a native of Persia or some part of the East; but, strangely enough, its native country is still somewhat uncertain. It was introduced into Western Europe, from Constantinople, in the end of the 16th century. It attains a great size, sometimes rising to the height of 100 feet, and extending its branches very widely, whilst they often droop almost to the ground. The leaves have long stalks, and seven obolate-wedge-shaped leaflets. The wood is soft, not very strong, nor very durable in the open air; but is used for many ordinary purposes, and by carvers, turners, &c. The bark is bitter and astringent, containing a bitter principle called Aescule; it has been used in tanning and dyeing; that taken from branches not very old has been extensively used on the continent of Europe as a substitute for Peruvian Bark. The rind of the seeds contains a colouring matter, which has been used in dyeing; the husks also are used in dyeing. They are an unpleasantly bitter, and contain so much of the saponaceous substance prevalent in this natural order, that when reduced to powder, they may be used for washing. They contain, however, a large quantity of starch, which, when extracted and freed from bitterness by means of an alkaline solution, is pleasant and nutritious. It is prepared on a large scale and at a cheap rate in France. Horse-cheesnuts have long been employed in various countries as food for oxen, sheep, swine, and horses, all of which are fond of them, and grow fat upon them. In Britain, however, they are still very generally allowed to rot beneath the trees. It is said that when the H. was first introduced into Britain, it did not perfectly ripen its seed, which it now does even in the northern parts of the island.—The other species of Aesculus are natives of North America. The foliage is very similar to that of the common horse-chestnut, the leaves and fruit, however, are in a much better state. The BUCK-EYE or AMERICAN H. (A. Obidenia) are very poisonous.—North America possesses also a number of species of a nearly allied genus, Pavia, with smaller foliage, smaller flowers, and very sweet fruit. The seeds of P. macrocarpa or P. edulis, the Edible Buck-eye, are eaten, either boiled or roasted. This species is a shrub with long and beautiful racemes of fragrant white flowers, which have longprojexed stamens. It is a native of the southern states, and seldom ripens its fruit in England. P. Indica is a lofty tree, growing at elevations of 800—10,000 feet in the Himalayas, and producing seeds very similar to those of the H., which, although bitter, are eaten in times of scarcity.

HORSE-FLY. See Forest-Fly.

HORSE-GUARDS, the name applied to a large public office in Whitehall, appropriated to the departments under the general-commanding-in-chief. The word Horse-guards is used conventionally to signify the military authorities at the head of army affairs, in contradistinction to the civil chief, the Secretary of State for War.

HORSE-GUARDS, ROYAL, or OXFORD BLUES, is the third heavy cavalry regiment of the Household Brigade. The regiment was raised in 1661 from the remnants of the disbanded army of the late Commonwealth. It has ever proved a loyal corps, although it readily transferred its allegiance from James II. to William III. It took part in Marlborough's campaigns; served under the Duke of Wellington in the Peninsula and at Waterloo, and has always been considered one of the finest heavy cavalry corps in the world. The guards of state for the sovereign are taken either from its ranks or from those of the Life-Guards. The present uniform consists of a steel helmet, with plume, a steel cuirass over a blue coatee, leather breeches, and knee-boots; the horses are black. The establishment of the regiment consists (1862) of 439 of all ranks, with 275 horses, exclusive of officers' chargers.

HORSEMANSHIP. Throughout history the art of managing the horse and riding on his back has ranked high among useful and graceful accomplishments. According to Caesar and Livy, the Romans were the first to ride; the Persians rode their horses without either bit or saddle, and guided them by the hand.
HORSE-POWER—HORSE-RACING.

sadly by using a small switch, which was applied to either side of the neck, according as they wished to turn. The Persians trained their horses to kneel to receive their riders, and were the first to introduce saddles. Saddles of a simple type, the stirrups that now in use were not known till the 14th c., and side-saddles were introduced about 1388. Stirrups were used in the 5th c., but were not common even in the 21st.

The two essentials for riding are a firm seat and a light hand, as without a combination of the two no one can become a good horseman. In every description of riding, the light delicate 'hand,' just feeling the mouth of the horse, and playing the bit in accordance with his movement, will insure success; and it is to this delicacy of wrist that we must attribute the ease and skill with which ladies often ride the most high-spirited animals, which, in rougher hands, would be unmanageable.

The first lesson in horsemanship is to learn to mount safely and easily; and the ordinary, and on the whole least objectionable way, is as follows: Stand at the shoulder of the horse, and, walking towards his tail, and taking the reins in the right hand, divide them by the middle-finger of the left till you feel the horse's mouth; then take hold with the left hand of a lock of the mane, lift the left foot into the stirrup, and, seating yourself as at a night hold, spring into the air, taking hold of the back of the saddle to assist in getting the right leg easily over the horse, steadying the fall of the body by the right hand on the pommeled, and then arranging the stirrups. In dismounting, exactly the reverse of this process is followed, or both feet may be disengaged from the stirrups at once, and the rider may vault from the saddle to the ground with great facility, and less risk of falling if the horse chance to move on.

There are four different styles of riding practised among modern civilised nations—viz., the military, road, hunting, and racing styles. The military style differs in many particulars from the others, as, owing to the long stirrups used, the soldier is obliged to sit well down in his saddle, with his body erect, the seat being preserved more by balance than by a tight hold by the leg or thigh.

In the style for road-riding, the stirrups are arranged at such a length that when the feet are hanging loose, they shall just touch the ankle-bone, and the rider usually selects the feet only as far as the 'ball' of the foot. In riding, have the horse's rear end in hand, to assist in supporting him, in case of stumbling; the stirrup, to be secure in case of shying; and a knowledge of handling the bridle, to ensure a quick and ready response. In hunting, a much firmer seat is necessary; the stirrup-leathers are about two holes shorter, the foot pressed 'home' in the stirrups, which otherwise would be apt to be lost in jumping; the leg from thigh to knee well forward, and nearly at right angles to the upper part of the body as inclined forward; the legs perpendicular, the heel well down, and the toe pointing nearly straightforward. This 'seat' the hunter has in common with all equestrian nations, as the Arabs, Tartars, Persians, Egyptians, Polish Cossacks, Magyars, and Circassians, the last-mentioned nation carrying it to such an extreme that the leg assumes the form of the letter V, with the knee for the apex. In riding at a fence, 'collect' the horse into the pace at which he is going to make ease to himself; keep him straight at the fence till he rises; 'ease' his mouth by leaning forward; take especial care not to confine it when he is making his effort, or you will pull him into the fence as he deserts it, and will give him less motive power and less chance of success. The jockey's seat is peculiar as his object is to give as much ease as possible to his horse, so that the rider is very much hollowed, frequently standing in the stirrups, and regulating his pull at his horse according to his orders.

As the strongest part of a horse, and also the centre of action, is situated at a point just behind his shoulder-blades, the nearer we can ride to this the better, and riding rather forward in the saddle is a relief to the horse, while leaning back, as it bears upon his loins—his weakest part—is a cause of fatigue. The grip in riding should be obtained by the knee, the thighs and the calves tightly. The thigh is the most essential part of a good and strong seat. Few riders whose thighs are short and round, have a good seat; while, on the other hand, jockeys and tall thin men, whose thighs are long, and more or less hollowed on the underside, are generally very firm.

No one can pretend to horsemanship without a knowledge of the proper action for emergencies. In case of strain, if a horse rises, the first thing you should do is to pull the reins back, not to give up in vain pulling, but guide him out of danger, and let him run till he is tired. A Bucephalus noselband is a great security against bolting. If a horse rears, loosen the reins, and lean forward; in hunting, the 'art of falling' consists in getting clear of your horse. In case of a horse kicking, keep his head up as much as possible, and sit firm in the saddle.

HORSE-POWER, a term used in expressing the force of a motive power. It is based upon the assumption that horses in general perform a certain constant amount of work in a specified time; an assumption which is evidently erroneous. The fundamental unit of work is the Foot-pound (q. v.); but in measuring the work of a horse by this unit, the estimates of the most celebrated engineers differ widely from each other: Boulton and Watt, basing their calculations upon the work of London dry-horses (working eight hours a day), estimated it at 33,000 foot-pounds per minute. D'Anubwsoon, taking the work done by horses in whams at the Newmarket, estimated the work at 16,440 foot-pounds, working eight hours a day; under similar circumstances, Desaguliers's estimate was 44,000; Smestow's, 22,000; and Tredgold's, 27,500 foot-pounds, the result being the same. It matters little, however, what number is assumed, provided the same be always used: and accordingly the original estimate of Watt is still counted a horse-power. In calculating the power of a steam-engine in terms of this unit, the general rule is to multiply together the pressure in pounds on a square inch of the piston, the area of the piston in inches, the length of the stroke in feet, and the number of strokes per minute, the result divided by 33,000, will give the horse-power; but it is necessary to deduct about 1/4th of the whole, as an allowance for friction.

HORSE-RACING dates from the times of the early Greeks and Romans, among whom it was a favourite sport. In England, Charles I., Cromwell, and Charles II. were noted Turf men; and the last-named monarch was a regular frequenter of Newmarket, which, partly from this reason, became the metropolis of racing. William III. and Queen Anne were also patrons of horse-racing. Flying Childers, bred in 1713 by the Duke of Devonshire, was long considered to have been
HORSE-RACING—HORSE-RADISH.

The fleetest horse ever known; he carried nine stones at Newmarket, and ran 34 miles in 6 minutes 40 seconds; he was never beaten, and produced 497 winning guides realizing £200,000 in stakes. The celebrated horse Eclipse, the fleetest from the time of Childers, was bred in 1764 by the Duke of Cumberland. Commencing at five years old, this horse won eleven plates, was never beaten, and was important owner of numerous winners. In the modern race-horse is considerably taller and of earlier maturity than the original type, partly from judicious crossing, and also from early high-feeding and training; yet there has been a loss of stoutness of frame, and although the four-square paru breed Arab has a chance with a modern thorough-bred.

The horses are entered as yearlings (a race-horse's age dates from the Ist of January in the year he is foaled), but as 240 enter the year, rarely more than 25 come to the post the two years afterwards, the majority being found practically useless for racing purposes, and the forfeits from these horses thus 'scratched' form by far the greater portion of the splendid prizes of the turf. (It has been calculated that there are 1500 thorough-bred good-mares in England; these produce annually about 1100 foals.) The value of a thorough-bred yearling depends entirely upon 'the fashion' of his blood: as much as 1500 guineas have been given for 6, 600 and 800 are by no means extravagant rates for promising colts. The training of the young racer commences in his second year, when he is placed under a trainer, in an establishment such as those at Newmarket, Milford, Richmond, Melton, Ispwich, Doncaster, Epsom, &c., where the downs offer a wide expanse of open country for exercise. The trainer's charge is two guineas a week; and for this, each horse is personally attended to and ridden by a specially attached and constant exercise, thus proceeding by gradual stages to gentle galloping and sweating, and finishing by testing the capacity of the colt against a competitor at a distance equal to the forterior race. It has been found that, practically, the speed of almost all horses can be equalised by addition or subtraction of weight; and so nicely is this capable of being adjusted, that the handicaps, which are arranged on this principle, provide some of the best races in the year. Thus, besides the Chester Cup, Doncaster Cup, Goodwood Cup, Liverpool Cup, Cesarewitch and Cambridgeshire stakes, all are run on these terms. For the great prizes of the turf, however, the 1000 and 2000 guineas for two-year-olds, the Derby (about £6000), Oaks (about £4000), and St Leger, for three-year-olds, the horses run upon an equality of age and weight.

Enormously large as are the stakes run for—upwards of £200,000 annually—this is as nothing to the money which annually changes hands in betting. We may divide betting-men into two classes—one who backs a single horse from judgment, or private information; and those who, without any knowledge of the man more calculating the odds, and take the field against 'any favourite.' The latter class are the professional betting-men ('the ring'), who devote themselves to the pursuit; the former is composed of the honest owners and their friends, who trust to their knowledge and tact.

Colossal fortunes have been made by the 'ring' in this way, and there are men perpetually attending the country races, and ready to accommodate any gambler by 'lacing' the field. As no debts incurred by betting are recoverable by law, they become debts of honour; and any 'defaulter' is only amenable to the regulations of the turf, which have been devised to insure, as far as possible, honest dealing. The Jockey Club is the great tribunal of sport in England, and its regulations are adhered to all over the country: it is composed of 64 noblemen and gentlemen, who take an interest in the turf. Newmarket Heath, the greatest racetrack in England, is attended to in virtue of the position and authority of its members, it is enabled to exercise a great check upon dishonesty and fraud. The seven annual race-meetings at Newmarket are as follows: the Craven, first week, second week, Easter meetings, second October, and the 'Houghton.' The principal races are for the 1000 guineas, 2000 guineas, Cesarewitch, and Cambridgeshire. The Epsom meeting is the most popular from London and from the interest attaching to the races for the Derby and Oaks. After Epsom, the Doncaster St Leger, for three-year-olds, claims the position of greatest interest; it is run for by the competition of the greatest Depth and breadth of racehorses, and is generally considered to be a test of the correctness of their results. Ascot is reckoned the most fashionable meeting in the year; it is held on Ascot Heath, in Berks, and here the best horses in England are displayed, and tabled with the best horses from every other racecourse. In the race for the Ascot Cup in 1874, West Australian ran the 24 miles in 4 minutes 27 seconds, the fastest race on record. Goodwood meeting, which is held in the Duke of Richmond's park, in Sussex, is also popular. There are upwards of 150 race-meetings held annually in the United Kingdom; upwards of 1600 horses run at these, and 160 jockeys are in constant employment. A good jockey is considered so valuable, that he is always retained by one or more masters, to receive a considerable sum, and these gentlemen have a call upon his services in a certain rotation. The regular pay of a jockey is £5 for a winning and £3 for a losing 'mount,' but there are so many contingencies that this gives no indication of the income of a jockey, which is often very large: £1000 has frequently been given by a grateful owner. Racing has become popular in France, Russia, Austria, Prussia, Sardinia, and other states of Europe, and the colonies of India, Australia, the Cape, and Canada.

In addition to the flat-racing in England, there are a great number of steeple-chases, where horses contend over natural and artificial fences, ditches, &c. The sport is dangerous, and has not been made to resemble the immense speed arising from competition, so that horses get too distressed to jump, and broken backs and ribs are the consequence. In America, trotting-matches are very popular, and their horses excel all others in that description of racing.

HORSE-RADISH (Armoracia), a genus of plants of the natural order Cruciferae, differing from scurvy-grass (Cochlearia) chiefly in having the valves of the seed-pouches destitute of prominent nerves. The species are annual, or biennial, herbs, with white or oblong, crenate root-leaves on long stalks, and elongate-lanceolate stem-leaves. It grows in damp meadows in the middle and south of Europe, is naturalised in some places in Britain, and is cultivated for the sake of its roots, which are scarified or grated down and mixed in salads, or used as a condiment with roast-beef. H. root is used also in medicine as a stimulant, and is often useful.
HORSE-RADISH TREE—HORSE-SHOEING.

In promoting digestion; it is also regarded as an appetite-stirrer, and it is thus supplied externally as a rubefacient instead of mustard. In vegetable gardening, the H. is generally planted very deep. It is very difficult to eradicate from ground in which it has become established, as almost any portion of the root will grow into a new plant. Another species, A. officinarum, a native of Hungary and Transylvania, has much larger flowers, and a rather less pungent root.

HORSE-RADISH TREE (Moringa pterygosperma), a tree of the natural order Moringaceae, a native of India and Arabia. It has bipinnate or tripinnate leaves, with roundish oblong leaflets, terminal panicles of white flowers, and a pod-like, 3-valved fruit, with roundish 3-winged seeds. The leaves, which are mildly pungent, are used in curries, and with vinegar: the roots, which are very pungent, are used for purposes like those for which the root of the horse-radish is used, from which they are not easily to be distinguished. The seeds yield the useful fixed oil called Oil of Ben (q.v.), and the bark a gum like tragacanth. M. optera, another species of the same genus, also a native of the East Indies, is cultivated in Egypt, Syria, and Italy, for the sake of the oil of ben obtained from its seeds. For the sake both of the pungent roots and of the oil, these trees are now cultivated also in the West Indies.

HORSE-SHOEING. The ordinary system of horse-shoeing is rude and irrational, and is the main cause of most lamenesses and of the majority of falls in riding and driving. Chief amongst its faults are the attempts to fit the foot to the shoe, instead of the shoe to the foot, and the wholesale cutting and rasping, and consequent injury to several parts of the foot. After the cautious removal of the old shoe, the crust on which it rested generally requires to be pared down with a drawing-knife, and its edge afterwards rounded with the rasp. Any ragged portions of the frog may also be taken off, and this includes the whole of the allowable paring or dressing of the horse's foot. The horny sole intended as a covering and protection of the sensitive parts beneath; the tough elastic frog, an insensible pad which obliterates concussion, and preserves the foot wide and free from contraction; the bars, an involution of the crust, which help it to support weight, and give it lateral support, are all too valuable for the frog or bars, and it is not considered injurious to the frog or bars, if, from constant cutting, the bars are unfit to aid the crust in carrying the shoe, it will be often advisable to shoe for a time with tips or half-shoes, keeping the horse as much as possible on soft ground, and waiting the healthy growth of the foot. In troublesome cases of thrust, such tips are also most serviceable, allowing the frog the natural healthy pressure for which it is intended, and with astringents and cleanliness, great expediting of a cure. Groggy horses should have the toe shortened, and turned up, as already advised; the frog and sole must be untouched, and the shoes made light and nicely fitted. Over-reach, or cutting of the heel of the fore-foot with the shoe of the hind, is remedied by filing round the posterior edge of the offending toe, and keeping that shoe as far back as possible on the foot. For speedy cut, which is common in horses with in-turned knees, the shoe should be carefully fitted, and no projecting portions left; the clinches must

A sound Fore-foot prepared for the Shoe.

Copied from Stoneberry's Horse in the Stable and the Field.

A, A, the heels of the crust; B, the toe cut out to receive the clip; C, C, the quarters of the crust; D, D, the bars as they should be left, with the full frog between them; E, E, the angles between the heels and bars, where corns appear; F, F, the concave surface of the toe; G, G, the bulbs of heels; H, the cliff.
HORSING—HORUS.

also be well hammered down. — Further information may be found in Lieutenant-colonel Fitzwgram's Notes on Shoeing Horses; Mr Miles's pamphlet on Horse-shoeing, originally published in the Journal of the Royal Agricultural Society; Professor Dick's Manual; and other veterinary treatises.

HORNS, a small but very old town and seaport on the east coast of Denmark, and one of the prettiest and most thriving in the country, is situated at the head of the fjord of the same name, 25 miles south-west of Aarhus. It contains two churches, has four bridges, and carries on manufactures of tobacco, and a considerable trade. Pop. 7250.

HOR'SHAM, a parliamentary borough and market-town of England, in the county of Sussex, is situated on a tributary of the Arun, 28 miles north-east of Chichester, and 35 miles south-west of London. The Court-house, a Gothic edifice; St Mary's Church, in the Early English style; and the Grammar-school, with an endowment of £412 a year, are the principal institutions of the town. The trade and manufactures are inconsiderable. H. returns a member to parliament. Pop. of parliamentary borough in 1861, 6747.

HORSLEY, Samuel, an English prelate, was the son of a clergyman of the Episcopal Church, and was born at St Martin's-in-the-Fields, London, in 1733. He was educated at Westminster School and Trinity Hall, Cambridge, where, though he studied hard, and laid in immense stores of knowledge, he took no degree in arts. In 1758, he became curate to his father, then rector of Newington, after succeeded to the rectory; a living which he held for thirty-four years, though he also enjoyed in the interval many other preferments. In 1767, H. was elected a Fellow of the Royal Society, of which he long continued an active member. In fact, the writings that first brought him into notice were scientific, and not theological. We may mention his Remarks on the Observations made in the late Voyage towards the North Pole, for determining the Acceleration of the Pendulum, in lat. 79° 31' (1774). Two years afterwards, he issued proposals for a complete edition of the works of Sir Isaac Newton, which, however, did not make its appearance till 1785. But the grand event in his career was the controversy with Wedgewood, which, considering the momentous nature of the subjects discussed, and the splendid talents of the combatants, may be safely pronounced to be the greatest theological contest of the 18th century. The impression at the time was, that so far as hard, merciless hitting goes, H. had decidedly the best of it. Rude in language, but panoplied in learning, contemplauous, defiant, dictatorial, his attitude reminds one of Goliath rather than of St Paul, and we cannot but feel that he is, at least, as much inspired by the ambition of the pupil as by the arduous of the Christian. The work that excited the controversy was Dr Priestley's History of the Corruptions of Christianity, and it was one of the propositions that was included the orthodox dogmatics of Christianity. M. H. reviewed the work with great severity in his charge delivered to the clergy of the archdeaconry of St Albans, May 22, 1753. Priestley replied the same year in a publication entitled Letters to Dr H. in Answer to his Animadversions, &c. &c. In 1784, H. retorted in seventeen Letters from the Archdeacon of St Albans in reply to Dr Priestley, &c. &c. These were, in return, met by a new series from Priestley, who, waxing warm with the fight, describes his antagonist as 'the incorrigible dignitary.' After a silence of eighteen months, H. again replied in his Remarks on Dr Priestley's Second Letters, &c., and in 1789 collected and published the whole that he had written on the subject. His series were rewarded with the bishopric of St David's in 1788, whence he was translated to the bishopric of St Asaph's in 1802. He died October 4, 1806. H. as character as a writer has been already indicated; it remains to be added, that as a bishop he was liberal and humane both to the clergy and the poor of his diocese, although vigilant and even strict in the discharge of his episcopal duties. H.'s works, besides the many already mentioned, consist of sermons and treatises on biblical criticism, on mathematics, and on classical subjects. A collected edition of his theological works was published by Longman 6 vols. 1845).

HORTICULTURAL SOCIETIES, associations for the encouragement of gardening, are now numerous in almost all civilised countries, but seem to derive their origin only from the beginning of the present century, when the London Horticultural Society was formed, chiefly through the exertions of Mr Mr Wedgewood, and Sir Joseph Banks. The society obtained a charter in 1808. The Experimental Garden of the society, the first of its kind, was established in 1817, and was removed to its present situation at Chiswick in 1822. The progress of the society has been very rapid; and its usefulness has been very great. Societies of the same kind soon began to spring up in Germany and other parts of the continent of Europe, and horticultural societies now exist in almost all the towns and in many of the villages and rural districts of France. The Prussian Gardening Society perhaps ranks next in importance to the horticultural society of London; and the Pomological Society of London has been very useful in regard to the cultivation of fruits. The horticultural societies, now so common throughout Britain, have done much to promote not only horticulture, hut habits of neatness and a taste for flowers among the humbler classes, of which the humanising effects have been very manifest and important. It is perhaps to be regretted that their attention has been so exclusively devoted to the cultivation of particular kinds of vegetables already in general use, and of those flowers known as the flowers of fashion.

HORTICULTURE. See Gardening.

HORUS, an Egyptian deity, whose name, Hor, means 'the day,' or 'the sun's path,' and is usually written in hieroglyphics by the sparrow-hawk, which was sacred to him. The old derivation from the Hebrew our, light, is now recognised as incorrect. Under the name of Horus were included several deities, as Haroeris, the Elder Horus (q. v.), and Harpocrates (q. v.), or the Younger Horus; Hor-sam-ta, Horus, the uniter of the upper and lower world, who was the second son of Athor, reigned in Annu, or Heliopolis, and emanated from the eye of the sun (Rosellini, M. d. c. t. 47); and Har-sets another form of the same god, represented as a boy wearing a triple crown, who existed from the commencement of things, a self-created being, and emanated from the Nu, or firmament; besides several others. But the principal Horus was H. the son of Isis (Har-ah-hen), represented as a naked child standing wearing a skullcap, or the crown of Lower Egypt. H. M. is first mentioned by Herodotus (ii. 144. n. 150) as the son of Amon and Osiris, and brother of Bubastis, the Egyptian Diana. Various accounts are given of his birth; he having been, according to one version, engendered by his mother Isis on the barren shore of the Nile; or, according to another account, begotten of Osiris after that god's destruction by Typhon. His birth was said to be premature, and he was
HORUS—HOSIERTY.

consequently weak in his lower limbs. In order to avoid the persecution of Typhon, he was brought up by Lessu the floating island of Chemmis, or Buto, in secret. Having grown up, he became Har-nef-set (Horus the avenger of his father), and, along with his s, avenged his father’s death (see Osiris), according to the best received tradition, vanquishing Typhon and directing the development of the Egyptian ritual, he cut off their heads for the souls of heaven, and their thighs for the wild beasts and fishes. Typhon is said to have been delivered bound in fetters to Isis, who released him, upon which H. tore the diadem off his mother’s head, but Thoth replaced it by the head of a cow. H. was often confounded with the elder Horus by the Greeks, but the monuments represent him as the type of royalty, the antagonist of Seth or Typhon, the avenger of his father Osiris, for whom he obtained the title of Elusiam and the waters of Elephanteion, conquered the north and south, and shared Egypt with Seth or Typhon, having held the government of the northern part of the country at the death of Typhon, he became sole monarch, and as last king of the dynasty of gods, reigned, according to different versions, 100 or 25 years. Numerous esoteric explanations have been given of this god, as that he represents the Nile, as Typhon the desert, the fruitful air or dew which revives the earth, the moon, the sun in relation to the changes of the year, or the god who presided over the course of the sun. He also represented three planets, Jupiter (Juppiter), the sun (Horus), and Saturn (Harco), and the wolf. The sparrow-hawk was sacred to him; so were lions, which were placed at the side of his throne. There was a festival to celebrate his eyes on the 30th Epiph, when the sun and moon, which they represented, were on the same right line with the earth. A movable feast, that of his coronation, is supposed to have been selected for the coronations of the kings of Egypt, who are described as sitting upon his throne. When adult, he is generally represented hawk-headed; as a child, he is seen carried in his mother’s arms, wearing the pschent or atef, and seated on a lotus-flower with his finger on his hip, as had any special relation with Eden or Hut, the ancient Apollonopolis Magna, where he was identified with Ra, or the sun. There were also Books of Horus and Isis, probably referring to his legend (Lucian, De Bomn. sive Gall. a. 185). The magnet was called his bone; he was of fair complexion.—Birch, Coll. of Abydes, p. 35: Wilkinson, Man. and Cust. vol. iv. p. 305: Tabolski, Pesth, iv. 4, p. 222: Champollion, Pesth, E. J.: Hucques, Dubb. Uni. Mag. xxvii. p. 187: Boeckh, Manetho, p. 61.

HORUS, a king of Egypt, named Haremhebi, who reigned at the close of the 18th dynasty. His reign has been placed at 1661, 1455, or 1446 B.C., but it probably fell about 1400 B.C. Although the lists of Manetho give him a reign of 30 or 36 years, no higher monumental date than his seventh year has hitherto found. He restored the worship of Amen Ra, which had been overthrown by the disk or sun worshippers, and conquered the Bara-

HORVÁT, István (Stephen), the Hungarian Varro, was born at Stuhlweissenburg, in 1784. From early youth to his death in 1841, H. cultivated all his rare abilities to historical research, with the double object of settling the question as to the origin of the Magyars, and of consoli-
dating Hungarian nationality through the scientific study of the Hungarian language. Among H.’s published works, the chief merit belongs to his Magyarország Tölapókére Régi Nevezetégeövel (Primitive Families of the Hungarians, Pesth, 1820), which has an five volume, and, in 1829, a volume, for it have been gathered from innumerable rare manuscripts, and other documents, partly foreign, partly domestic. It is a monumental work in genealogy, connecting some of the living Hungarian families with the chiefnesses who were with Arab at the end of the 8th century. In 1814, appeared at Pesth, Defence of the Kings Lewis and Mathias Corvinus; in 1821, two volumes of Anweres to the Questions on Philology, put by the National Museum at Pesth, in 1825, Sketches from the Oldest History of the Hungarian Nation; in 1828 and 1829, Researches on Biblical Expressions, &c. H. was for many years editor of, and later, chief contributor to the Tudak dunk Gyaj termény, or Scientific Magazine.

HOSEFA, the third (in the number of time) of the twelve minor prophets of the Old Testament, delivered his prophetic message, according to the inscription of his book, during the reigns of Uzziah, Jotham, Ahaz, and Hezekiah, king of Judah, and of Jeroboam II, king of Israel. Reckoning even from the last year of Jeroboam’s reign (about 785 B.C.) merely to the first of Hezekiah’s (about 725 B.C.), his career must thus have extended over nearly 60 years; but most—especially of modern scholars—seem inclined to regard this period as improbably long, though some calculations (e.g. Horsley’s) make it even longer. Whether H. belonged to Judah or Israel, cannot be determined with certainty; but the greatest critics, with the exception of Maurer, maintain him to have been an Israelite. His prophecies, which are mainly directed against Israel, give a frightful picture of shameless idolatry, licentiousness, iniquity, horror, and eager inclination towards disadvantageous and demoralising foreign alliances, and they may be regarded as appropriately to the period of anarchy and vice which followed the luxurious reign of Jeroboam II.

HOSHUNGARAD, a town in Central India, stands on the left or south bank of the Nerbud, in lat. 22° 44' N., and long. 77° 44' E. Its district of the same name is a subdivision of the Sogor and Nerbuda territory, belonging, as such, to the sub-presidency of the North-western Provinces. It is said to contain 1916 square miles, and 242,641 inhabitants. Besides being so fertile as to be styled the garden of the country, it possesses abundance of excellent coal.

HOSIERTY, in its most limited sense, refers to the manufacture of stockings (hose); but in its more general application, it comprises all knitted goods, whether made by hand or by machinery. The use of stockings originated in the cold countries of the north, and probably the first were made of skins, and subsequently of cloth; they were also, until a comparatively late period, made all in one piece with the trousers, constituting the trunk-hose of our ancestors; but these garments were separated; and the art of making stockings in the United Kingdom in Scotland, about the commencement of the 16th century. Certain it is that knitted stockings found their way to France from Scotland, and led to the
HOSPITALS.

Establishment of a guild of stocking-knitters, who chose for their patron saint St Firac of Scotland. In 1559, William Lee, of Woodbridge, Nottinghamshire, entirely altered the hosery trade, by inventing the stocking-frame, although he did not live to enjoy much benefit from it, it soon became a very important aid to the commerce of this country. During the Protectorate, the stocking-frame knitters obtained a charter, and extended the manufacture through the provinces of England, but with all the disadvantages of a monopoly, which eventually led to legal proceedings, by which the charter was set aside in 1733. Since that time, many improvements have been made in the stocking-frames, and it may be fairly said that four-fifths of the stockings now worn through the world are made by the manufacturers of Great Britain. The ingenious contrivances by which this vast work is produced, will be described under Stocking-frame.

Stockings are made of cotton, of worsted, or of cotton and worsted mixed, called Angola, and silk. They are each made of two distinct kinds. The beat are made in a flat web, which has to be sewn at the back as well as the foot, and it is so made that when the two edges are brought together at the back, they give the form of the calf. The common or raked stockings are woven in a circular frame, and are of a cylindrical web, of equal width from top to bottom; these have to be stretched on boards to give them the shape, and are ironed with hot irons whilst on the board, to make them retain the shape of the board. The foot is formed by cutting the web and adding a small piece for the sole. Nottinghamshire, which gave birth to the inventor of the stocking-frame, is still the centre of the hosery trade in Great Britain. At Belper, in Derbyshire, stockings of very fine quality are produced; but the cheaper sorts of stockings, gloves, singlets, etc., are made in Nottingham or its immediate neighbourhood.

HOSMER, HARRIET, an American artist, was born at Watertown, Massachusetts, in 1831. As she had a feeble constitution, her father, a physician, encouraged her to strengthen it by out-door exercises, and she became an adept in shooting, riding, rowing, skating, and swimming. She also showed a talent for sculpture by modelling figures in clay. To prepare herself for her chosen career, she studied anatomy and surgery with her father, and afterwards at the medical college at St Louis. Returning to her home in 1831, she modelled her first work, 'Hesper,' which had so decided a success that she was sent to Rome, where she became the pupil of Gibson. In his studio, she has modelled busts of 'Daphne' and 'Medusa,' and a statue of 'Eone' for a gentleman of St Louis; and the much admired statue of 'Beatrice Cenci' for the Mercantile Library of that city. Her statue of 'Puck' has been honoured by orders for copies from His Royal Highness the Prince of Wales, and the Duke of Hamilton. Her most ambitious work, finished in 1839, was a colossal statue of 'Zenobia in Chains.'

HOSPI'ENCE, the name given to the pious establishments kept up by the monks on some of the Alpine passes, for the purpose of affording assistance and shelter to travellers. The oldest of these is that on the Great St Bernard (see Bernard, Great St), which the priests of the canton of Valais gained possession of in 1525, and afterwards fitted up in a comfortable manner. A hospice likewise existed on St Gothard as early as the 13th century. At present, however, it is inhabited not by monks, but by a hospitaler, who entertain travellers gratis, and accepts no remuneration beyond a present.

Similar establishments are found on Mont Cenis, the Simplon, and the Little St Bernard.

HOSPITAL, in Law, is used in England to denote an eleemosynary corporation founded for the purpose of supporting certain descriptions of persons; whereas, in Scotland, it more frequently signifies a municipal endowment for the reception and care of the indigent poor, as well as support of children. In both countries, it is also used, popularly, to denote an institution for dispensing medical assistance to the poor gratuitously.

HOSPITALS, Damest of the. See SISTERS OF CHARITY.

HOSPITALLERS, charitable brotherhoods founded at various times and in different countries, for the care of the sick in hospitals. The vow to devote themselves to this work of mercy is, in all these brotherhoods, superadded to the ordinary vows of poverty, chastity, and obedience, which are common to all the religious orders in the Church of Rome. One of the earliest recorded instances of a hospital served by such a brotherhood is that of Constance in the 13th century.

The KNIGHTS OF ST JOHN OF JERUSALEM (q.v.), as also the TEUTONIC KNIGHTS (q.v.), were originally hospitals. The hospitalers of Our Lady of Christian Charity were founded near Chalons in the end of the 13th c., by Guv de Joinville; a similar body at Paris in 1294; and the hospitalers of Our Lady Delta Scalz about the same time at Siena. The history of the Brethren of Mercy, founded by St John of God, will be found under that name. There are many other local institutions or congregations, all of which, however, recognise the same general rules, and follow the same general organisation.

HOSPITALS are so called from the medical hospitals, or more properly the class of hospitals established very generally for the reception and relief of lepers, whose malady was one of the scourges of Europe. These leper hospitals were very commonly in England and in the Low Countries called 'Spitals,' hence the frequency of such names as Spital, Spitalfields, &c. The leper hospitals, and other kinds of the old hospitals, disappeared with the improvement of society, and such hospitals began to be established in the modern form of hospitals. Of public establishments under this general designation, there are now, as is commonly known, three distinct classes—hospitals for the reception and treatment of the sick and hurt, hospitals for the board and education of children, and hospitals for the reception and permanent board of poor old persons of both sexes. Hospitals of these several classes are numerous and on a munificent scale in Great Britain, where they take the position of leading charities in the country. As, in the present work, the more remarkable hospitals receive some notice under their respective heads, we need here only mention a few general observations.

HOSPITALS for the sick and hurt are in some parts of England and Scotland termed Infirmaries. Under whatever designation, institutions of this kind are now established in all parts of the civilised world on a vast scale, and are usually termed charity, or, as in France, chiefly from the funds of the state or the civic municipalities. The primary or more important object of all such institutions is to mitigate bodily suffering, whether that arises from natural or accidental causes, in which case they are indispensable as a refuge to all who are unable to pay for private medical or surgical aid, or as a convenient means of succour on emergencies to persons of every rank and degree of opulence.
HOSPITALS.

While such is the main object of these benevolent institutions, they are in numerous instances serviceable as schools for medicine and surgery; as such, no university, at which these and kindred branches of learning are taught, can be said to be complete without the adjunct of a well-organised hospital, where professors can practically educate their pupils by pointing out varieties of disease and injuries, and which holds the great advantage of giving them the best specimens of hospitals found in university towns—as in London, Paris, Edinburgh, and some other cities famed as schools of medicine and surgery. The older of the London hospitals are, St. Thomas's, 1553; St. Bartholomew's, 1546; and Bethlehem, 1547. A considerable accession to the number took place in the reign of George II., when society became alive to the value of such institutions. It was at this period that the Royal Infirmary of Edinburgh was established (1736).

The antiquity of British hospitals sinks into insignificance in comparison with that of some institutions of this kind on the continent. The Hôtel Dieu, in Paris, which is alleged to be the most ancient hospital in Europe, was founded in the 7th c., and long known as the Maison Dieu, received the benefactions of successive sovereigns. It is now conducted on a stupendous scale. Houses of this kind in every city and town of France are conducted with peculiar strictness and administration. They have been for ages the object of religious influence on a great scale, and are conducted in a religious sisterhood, renowned for its practical benevolence, the Sisters of Mercy. A striking example of these women's unselfish and useful labours is furnished at the great hospital for the sick, lying-in women, and infants, in Paris, erected gratuitously by them.

In London, Paris, and other large seats of population, the practice of medicine by professors, likewise the necessity for classifying and properly attending to large numbers, have led to the establishment of hospitals for special departments of medical practice. Thus, besides the general hospitals, there are now lying-in hospitals, ophthalmic hospitals, consumptive hospitals, children's hospitals, &c.—each with its peculiar accommodation, and its appropriate staff of officials. Independently of these, there are hospitals for the treatment of mental maladies, of which Bethlem and St. Luke's in London, and the establishments in Paris, known as Hospices, are examples. To this class of institutions belong Lunatic Asylums (q. v.), also asylums for the reception and treatment of naturally imbecile persons, and public institutions for the insane. Some time in France and Switzerland, being out of recent establishment in Great Britain. To all these institutions under civil administration, are to be added those hospitals which are maintained by the English, French, and other governments for the military and naval services.

No part of the social economy of European countries is so perfect in its organisation, so purely humane, and so unobjectionable on the score of promiscuous charity, as the institution of public hospitals or infirmaries. As means of relief and schools of medicine, they appear to be absolutely essential to every dense community; not the least of the inestimable value of public benefactions lies in the prompt and liberal action, they instep to stem contagious distempers, which, if unchecked on their outbreak, might visit and decimate families who are not rendered valuable to the state by the value in the midst of poor communities, invaluable like hospitals, are a means of staying the course of contagious distempers. The other institutions to be noticed are those called in France Maisons de Santé. These establishments are private hospitals and treatment hospitals for the reception of patients liable and disposed to pay a small sum for board and

43
medical or surgical attendance. A common charge is from three to five francs a day. Under the name of this institution, an attempt has been made to introduce this kind of institution into England, where, however, from various circumstances, including the generally good home-accommodation of the middle and sub-middle classes, the institution has not assumed the same popular shape as it is in Paris.

Hospitals for the board and education of the young are more varied in character and more numerous in Great Britain than in any country in the world. Consisting for the most part of large and handsome buildings, placed in salubrious situations in the environs of cities, some are specially adapted for boys, some for girls, and less frequently they are for both; some are maintained by endowments from deceased benefactors, some by funds connected with trade incorporations, and some by casual donations and subscriptions. The oldest, and those on the most munificent scale, are of the class first mentioned; as, for example, Christ's Hospital, London, and Heron's Hospital, Edinburgh. Donaldson's Hospital, Edinburgh, belongs to this class; and so likewise does the Girard College, Philadelphia, which costing for construction nearly two millions of dollars, and giving accommodation to upwards of 300 orphans. Another method, exceeding in point of architectural grandeur, or in munificence of private endowment, by any European hospital for children. In the whole of this class of institutions in Great Britain there is a similarity of arrangements. The inmates and orphans are of both sexes; and in the case of parents in reduced circumstances; they are admitted at about six or seven years of age, and kept till about fourteen; they receive gratuitous board and education within the establishment; and they wear a uniform and conform to the fancies of the directors—the dress being in some instances in England antiquated and ridiculous. There is ordinarily a keen competition among parents and guardians to procure the admission of children into these hospitals, for the benefit to be secured is deemed equal to a gift of £200 to £300. Hence, as may be supposed, the charity, to call it so, is frequently abused. As residence within such establishments for a period of six or seven years, interrupted only by holidays, involves a withdrawal to that extent from the family circle, serious objections have lately been taken to the marked and necessary deficiency of hospital training. On this ground, as well as from the usual tendency, hospitals for children are suffering in public estimation; and extended in number beyond all reasonable bounds, as they are in Edinburgh and some other places, are remonstrated against as being inconsistent with a sound social economy.

Hospitals for indigent old men and women are found in several European countries, but nowhere are they so common as in Great Britain and the Netherlands, where begging is rigorously proscribed by the police, and almshouses assume the character of rates for support of the poor. The workhouses for the reception of parish paupers are the humblest variety of these hospitals, though as seen in some parts of England and Scotland, they are on a vast scale of accommodation, adapted to the wants of unions or clusters of parishes. Considerably above these in point of comfort and liberality of management, are the hospitals endowed by individuals or by incorporations for persons who once occupied a respectable position, and have through misfortunes lapsed into decayed circumstances. Almost every city of any note in the United Kingdom has one or more of this species of hospital, the claim for admission being ordinarily a privilege of local burgesses or members of incorporated crafts. Analogous to this class of institutions are Greenwich Hospital for superannuated mariners, and the almshouses of the Hospital, Chelsea. In England there are numerous establishments called Alms Houses. These are of the nature of hospitals for indigent men and women of respectable character, but with this difference, that instead of all living in wards under one roof, the inmates are each provided with a small dwelling for him or herself, and receive the means of separate livelihood. These establishments, consisting of clusters of neat, small cottages in contiguity, or of separate dwellings grouped in the form of a spacious building, abound in London and its vicinity, where they afford pleasing examples of the munificence of opulent benefactors, and incorporated city companies. At St. Cross, near Winchester, and at Coventry, there are Alms Houses curious from their antiquity and external appearance. The noblest example of this class of institutions is the Charter-House, London, described in the present work.

Hospitals, Military, establishments for the reception of the sick and wounded of an army. There are the so-called Regimental Hospitals, and the medical officers of the regiment; next, there is the Divisional Hospital, presided over by staff medical officers, for the benefit of all the corps in the division; and, lastly, there is the General Hospital, applicable to the whole force. In these hospitals, the medical officers are responsible directly to the Secretary of State for War for all purely medical functions. With regard to discipline, inspections, and other military duties, the principal medical officer is responsible to the commandant of the regiment or division, who in his turn is answerable to the general-in-chief for the state of the hospitals in his command. Soldiers while in hospital are subjected to a stoppage of 5d. a day from their pay if abroad, 10d. if at home. The amount of these stoppages for 1862 was £111,000, in addition to which the military hospitals were estimated to cost the country £101,819. There are several large military hospitals at home—e.g., Netley (q. v.) and Plymouth, but abroad there are such establishments at Malta, Bermuda, Halifax, Jamaica, the Cape, and Hong Kong. The annual cost of the staff for naval hospitals amounts to about £20,000.

Hospodar is the title now generally used by the governors of Moldavia and Wallachia. Formerly, they were called by the Turks, Beys; by the Slavs, Wojewoda. The latter title is frequently given in connection with that of hospodar, the term wojewod signifying the right and dignity of leading the army (being thus identical with Duke), while hospodar (gospodar, gospod, gospodan, in the Polish or Serbo-Slavonic dialects) means simply, master (dominion). Formerly, the Lithuanian princes were likewise called hospodars, and the Polish kings, down to the time of Sobieski, assumed this title in their diplomacy; the claim to it being originally a privilege of local burgesses or members of incorporated

434
of Russia, and in ordinary conversation signifies master. See Moldavia, Wallachia.

HOST (Lat. hostia, a victim), the name given in the Roman Catholic Church to the consecrated bread of the Eucharist. It is so called in conformity with the ancient belief that the Eucharist is a 'sacrifice,' in the strict sense of the word. The host in the Latin Church is a thin circular disc of unleavened bread, made of the finest flour, and generally bearing some emblematic device, as the OECUMEN, the Lamb, a V, or initials of words having reference to the sacrifice. In the Greek and other Oriental churches, as well as in the various Protestant communities, the Eucharist is celebrated in leavened bread, only differing from ordinary bread in being of a finer grade, and the grounds of separation from the West alleged by Michael Cerularius was the western practice of using unleavened bread. The Greek and Protestant controversialists allege that, in the early church, ordinary unleavened bread was used by the Roman Catholics, and that at Malatun they held, a content for the antiquity of the use of the unleavened bread, and especially for its conformity with the institution of our Lord, inasmuch as at the paschal supper, at which 'he took bread, and blessed, and brake it,' none other than the unleavened was admissible (Exod. xii. 8, 15; Levit. xxiii. 5). See Klee's Dogmaticii, iii. 190.

HOST, JENS KLUGH, a Danish historian, born at St Thomas, 13th September 1772, and died 26th March 1844. The great aim of his literary career was to create a conviction of their unity among the Scandinavian nations. With this view, he established, in company with Nyerup, Pram, and Baggesen, the Scandinavian Literary Society, which originated the journal entitled the Scandinavian Marsch, and his most important work is Count Struensee and his Ministry (3 vols. Copenhagen, 1824), which was the first attempt to delineate, in a thoroughly impartial manner, the events of that singular period in Danish history. Among his other writings are: Norendt Blaude; Ethnographie; Danskere; A Swedish Grammar and Dictionary for Danois; Lectures on the Swedish Language and Poetry; Life and Government of Gustavus Adolphus; Memorials of the Life and Character of the celebrated Bishop of Copenhagen; History of the Danish Monarchy under Christian VII.

HOSTAGE (through the French otage (ostage), from the Latin obiace), one given in pledge for the performance of conditions. When a town capitulates, victors and vanquished usually give in the custody, one of the other, several officers, as pledges that each party will duly carry out the terms stipulated. When the terms are fulfilled, the hostages are exchanged; but if the terms be evaded, the opposite side has the right to take possession of the hostages, and, in case of death, the hostages in its possession. It is needless, however, to add that, in modern civilised warfare, the circumstances would have to be very remarkable indeed to be held to justify so cruel a measure as the execution of a family or a nation, as hostages.

HOSTILIUS, TULLUS, grandson of Hostus Hostilius, the champion of Rome in the first war with the Sabines, succeeded Numa Pompius on the throne of Rome, 670 B.C. According to Livy and others, he was killed in the battle of the same year with the Latins, by the combats of the Horatii and the Curtatii, for the decision of the question of supremacy between Rome and Alba, which was decided in favour of the former: he fought against Ficilum and Veii, and conquered some cities, destroyed Alba, and removed the inhabi-

HOTBED, a heap of fermenting matter, covered with a layer of earth, and generally surmounted with a frame, for the cultivation of plants which require more than the natural heat of the climate and season, but not so much as to render the hot-house necessary. The heat is the result of fermentation. Hotbeds not being expensive, are in very general use in the northern parts of Britain, for raising ornamental plants from seed in spring, to be planted in the open ground as summer advances, &c. The material most used in stable-duf or a mixture of horse-dung and litter; but tanners' bark, leaves, the waste of flax, cotton, or woollen factories, &c., are sometimes substituted for it. The heat of a very rapid fermentation being too great, it is necessary that this be over before the hot-bed is planted; and it is usual, on this account, to prepare the materials for some time before it is formed. A hot-bed is made highest at the back, sloping—in the northern parts of the world—towards the south. The bed extends on all sides six inches or thereby beyond the frame, which has a movable glass sash or sashes, according to its size. The thickness of the hotbed, and of the earth upon it, are accommodated to the purpose intended, and the degree of heat required. When the heat decreases, it is for some purposes necessary to keep it up by linings of the same material as the hotbed, added to the sides of it. The cushions of hotbeds must be partially removed during the day, to permit ventilation and the escape of vapour.

HOTHOUSE, a building intended for the cultivation of exotic plants requiring a higher temperature than that of the open air. The term is sometimes employed to include even the green-house and conservatory; but generally it is used for green-houses in buildings in which artificial heat is kept up at all seasons of the year, as the Barks-towe (q. v.), Dry-stoove (q. v.), forcing-houses, pinery, peach-house, &c. Hothouses resemble green-houses in their general form and structure, and with most of the same varieties in both. It is important that they have a good exposure, so that the plants may enjoy as much sunshine as possible; and the free admission of air to the utmost extent allowed by the requirements of climate, is very favourable. The old method of heating hothouses is by furnaces and flues, but the other modes practised are by steam, or by hot water led through the house in tubes, and by hot air admitted into the atmosphere or the air. Into the details of these modes, we cannot enter.

HOT SPRINGS, a small village in Arkansas, United States, America, 53 miles west-by-south of Little Rock, and celebrated as a resort for invalids to the hot springs which give the name to the village and the district. Fifty miles south and 150° F., break out from the west side of a mountain, and flow into a creek, which empties into the Wachita river, six miles distant. There are also cold chalybeate springs, much frequented, and sulphur springs, in the same county.
HOT WALLS—HÔTEL

HÔTEL, originally Hostel, or Hostelrie, a French term applied to an inn, or house for the temporary accommodation of travellers. The term, however, is also applied in France to the private mansion of a distinguished person, and in like manner the word inn was at one time indifferently used in England to signify the town residence of a great man. The name hostelier was applied by Chaucer to a public inn, and till a more recent period it was similarly used in Scotland. From its general use comes the designation hostler, which originally signified the keeper of the inn or hostel. Only in recent times has the significant old English word inn been eclipsed by the reintroduction of hostel, under the softened form of hôtel.

An account of inns ancient and modern, under whatever designation, would form an interesting chapter in social history. The Caravansarai (q. v.) of the East is the most ancient species of inn of which there is any notice. The Greeks and Romans did not improve on the quality of these oriental establishments. Their inns, if worthy of the name, were little better than receptacles for a crowd of wayfarers, who were supplied with cooked food and wine were dispensed to the hungry and thirsty stranger. Along their highways, the Romans gave encouragement to these primitive varieties of inns; the best of such establishments being called cuoreia, or taberna denticaria, while those of an inferior kind were known as psicon, of which some specimens have been disclosed at Pompeii.

The duties of hospitality and also the obligations of religion long postponed the introduction of regular inns. In medieval times, the castles of the barons offered shelter with straw, and sometimes food, to the wayfarer of high and low degree, and there are traditions to the effect, that to pass some of these strongholds without calling to render obeisance, and receive the hospitality of the owner, was deemed an insult. But the monastic establishments, great and small, scattered over every part of Europe, formed the chief hospita (see Settlev). With the general improvement of society and the increasing concourse of travellers came the modern inn, or professional hostini, which entertainment for man and horse was afforded as a business. Nowhere in Europe did this class of establishments so soon attain to a determinate and respectable character as in England.

Growing first into importance in London, York, Oxford, Bristol, and some other cities, the substantial and well-managed English inn was imitated on a smaller scale in the different provincial towns, and gained a good standing in national usage before it spread to Scotland; the inns of which, even up to the middle of the 18th c., were on a mere scale of accommodation. It is not necessary to call to mind more than a few of the interesting old inns in London, all celebrated less or more for names, which constitute a series of specimens of different times, of Clement Dane's, and Angel at Islington; the Bell, Warwick Lane, Newgate Street; Belle Somoge, Ludgate Hill; Bull and Mouth, St Martin-le-Grand; Four Screas, Bishopsgate Street; Saracen's Head, Snow Hill; Golden Cross, Charing Cross; Horse, Fetter Lane; and Tabard (now Talbot), Southwark. For brief notices of these and others, see Curiosités of London, by J. Timbs. For the most part, the old inns of London, Westminster, and Southwark, consisted of a building round a courtyard, entered from the street by a wide covered passageway. The ground-floor was disposed as stables, kitchens, and other offices, with a large reception-room; above, were the lesser apartments and bedrooms. The most interesting of hanging wooden galleries, whence the inmates could look down on the busy scene of arrivals and departures in the courtyard beneath. Some specimens of these old inns with open galleries still exist, such as the Tabard, now named as the hostelry from which Chaucer's pilgrims set out for Canterbury. There is reason to believe that this form of construction was derived from the arrangement of ancient Roman villages, which consisted of buildings round a series of courtyards; hence, also, the form of French hôtels, public and private. Modern Italy has examples of inns of this form. We may allude particularly to the HÔTEL de Ville at Milan, and the Albergo delle Due Torri at Verona. East having hanging galleries round a courtyard in precisely the old English style.

Of the character and management of the inns of England, with their offers of 'entertainment to man and horse,' we are favoured with innumerable glimpses in the fictions of Fielding, Smollett, Goldsmith, and others—the jolly hostess, the obsequious waiters, the bumbling chambermaids, the host and his tabard the traveller's nag, and above all the garrulous host-was, who, whether company to his guests, tells them the news, and at dinner, according to use and wont, places the first dish on the table. See Dr Syntax's Tour in Search of the Picturesque, illustrated by Rowlands, for some humorous delineations of inn- usages. The great personal comfort and independence of feeling enjoyed in English inns is frequently referred to in literature. Archibald Leighton, who died 1684, in the Bell, Warwick Lane, 'often used to say, that if he were to choose a place to die in, it should be an inn; it looking like a pilgrim's home, to whom this world was all an inn, and who was weary of the noise and confusion of these last all one obtained what he desired."—Burnet's Own Times. Dr Samuel Johnson, as is well known, expatiates on the delights of an English inn; on one occasion, as related by Boswell, repeating with great emotion Shenstone's lines:

'Who'er has travelled life's dull round, and in his wanderings these stages may have seen May think to see he still has found The warmest welcome at an inn.'

English inns have not lost their reputation for comfort and the attention paid to guests; but the almost entire alteration in the methods of travelling by the introduction of railways has left them
HOTTENTOT COUNTRY—HOTTENTOTS.

...considerably behind the requirements of the age. Except in the smaller towns and villages, they have been superseded by hotels—that is, houses of a more pretentious kind. The better classes of these hotels contain private parlours for families or individuals who choose to be waited on by waiters, and also a large room, known as a table d'hôte, for travellers generally. Houses frequented by commercial travellers have a room set apart for this class of customers. The plan of taking meals at a table d'hôte has not hitherto made much progress in the smaller towns; but in London, and elsewhere in England, the demand is considerable.

The greater number are merely private houses transformed for the purpose, and are inadequate to meet the increased demand on the railways. The truth is, the establishment of inns or hotels is a part of Great Britain that has hitherto been neglected. It has been developed as a profitable investment for a large capital. The business of innkeeping has been thought a little derogatory, and few except old waiters, who had realised some money by their services, embarked in the business. On the contrary, the hotelkeeper is a considerably higher social status. A large capital is invested, the keeper or manager is a man of local note, and the waiters or garçons are young men who follow the business as a profession, which they expect to rise by their diligence and acquirements.

In point of fact, the garçon is much above the English waiter in his aims. He voluntarily undertakes a kind of curriculum of education, by passing from the hotels of one country to those of another, and does not consider himself proficient till he speaks German, French, Italian, and English; at the very least, if of German birth, speaking French with fluency. Some good and capacious hotels, built distinctly as such, have lately been established at the principal railway termini in London, also at Dover and a few other places. With these exceptions, the hotels of England are far behind the new high-class hotels of the continent; nor do we know of any English hotel which approaches in grandeur or extent to the Hôtel de l'Homme in Paris, the Metropole at Geneva, or some of the magnificent hotels at Hamburg. But while we now call ourselves a nation of hoteliers, and people who, in many cases, are compelled to build several hotels in London, worthy of the demand, and corresponding to the vastness of modern demands.

In England, the hotel system of living is simply that of paying for what is called for, with the addition of a certain charge per diem for the rooms which are occupied; in France and other continental countries, this plan is so far modified by the plan of dining at a table d'hôte, which lessens the general expenses. Both in English and continental hotels, the charge for attendance is now made explicitly in the bill, a very grateful improvement. The ordinary hotels in all parts of the United Kingdom are licensed to sell wines, spirits, and other excisable liquors, and therefore come under the category of public-houses open to the supervision of the police. In the higher-class hotels, the supply of liquors is confined to the resident guests; and it is only in the others that drink is sold as in taverns.

Latterly, there has sprung up a class of houses, some of them on a considerable scale, known as Temperance Houses, in which the supply of liquor is confined to the resident guests; and it is only in the others that drink is sold as in taverns. See Tavern. Throughout the United States of America, the system of hotels has taken a peculiar turn. The hotels are built for the purpose, and usually very large; with few exceptions they are conducted as boarding-houses on the plan of charging so much per diem, everything included, except what is obtainable in a large drinking-room called the bar. A common charge is about 10s. 6d. a day. All the meals are given with liberal profusion in the table d'hôte fashion; and as these establishments become known to friends, for example—makes no difference of charge, the system, though simple and adapted to a constant flow of customers, is not without its disadvantages.

Elegant in their architecture and commodious in their interior arrangements, the American hotels are up at great expense, as may be judged from their extensive accommodation, which ranges from 180 to 800 rooms. The Astor House, the St. Nicholas, and the Metropolitan, at New York, are among the largest and most splendid of these establishments. The system of American hotels is generally followed in the British colonies. W. C.

HOTTENTOT COUNTRY, a region of South Africa, stretches indefinitely to the North of the Cape Colony, having the Atlantic on the W., and the Bechuanas and Kafirs on the E. In long. it extends between 15° and 27°; and in lat. between 31° and some line to the north of the tropic of Capricorn. This territory is bounded on the south by the Orange river, is almost useless for navigation; and though here and there well wooded, yet the surface is chiefly an arid desert. The only examples of civilisation are to be found in several missionary establishments.

HOTTENTOTS is the name generally given by Europeans to a singular race of people, supposed to be descended from the aborigines of Southern Africa, and now dwelling for the most part in and about the English settlement of the Cape of Good Hope. The origin of the name Hottentot is uncertain. Some think it is of Dutch origin; a word coined by the early Dutch settlers to convey by the sounds Hot en Tot, Hot and Tot, some idea of the peculiar clicking noise made by the people when speaking. Dampier, however, wrote the name Hothoden, instead of H.; and Franchard says that it is probably a corruption of Homteniqua, the name of a particular tribe now extinct, or at least unknown. They now call themselves by various names, supposed to be those of tribes, as Attaquas, Hessaquas, Daumaras, Saals or Saaps, Namaquans, and Korannas; and by the collective name of Quai-que, or Khiuigkhiu.

In the ethnological classification given by Dr. Latham, the H. are ranged under the second great division of the human family—Africa. In the older classification, that of Blumenbach, they were ranged under the third great division of the human race—the Ethiopians—under which division that author also places the negroes. But the H. are not like the negroes, and are more akin to the Mongolians; having broad foreheads, high cheek-bones, olive eyes, and a dirty, olive-coloured complexion. The width of the orbits, their distance from each other, the large size of the occipital foramen, are points in which the H. resemble the northern Asians, and even the Equinums. The person of the Hottentot, when young, is remarkable for its symmetry. The joints and extremities are small, and the males look almost as effeminate as the women. The face, however, is in general extremely repulsive, and with the exception of John Barrow, in describing the Hottentot women, observers of them that before child-bearing they are models of proportion, every joint and limb rounded and well turned, their hands and feet small and delicate, and their gait by no means deficient in grace.
HOTTONIA—HOUND.

HOTTONIA, a genus of plants of the natural order Primulaceae, of which one species, H. palustris,

Water Violet (Hottonia palustris): a, corolla; b, calyx; c, pistil; d, stamen.

Water Violet or Featherfoil, is among the most beautiful of British aquatic plants. It is not found in Scotland. Its leaves are all submerged, crowded, and much divided: the large, beautiful, pale purple, whorled flowers alone rise above water on a long cylindrical stalk. Other species of H. are found in the East.

HOUARIOS are small coating-vessels and pleasure-boats used in parts of the Mediterranean. They bear lateen sails, and have each two masts and a bowsprit.

HOUND (Ger. Hund), a name commonly given to those kinds of dog which are used in hunting, but more especially, at least by systematic writers on dogs, to those which hunt by scent rather than by sight. When this definition is adopted, greyhounds are not regarded as true hounds. Examples of true hounds are found in the Bloodhound, the

Old English hound (Canis sanga).

Hound (Canis sanga).

The H., as a distinct race, first became known to Europeans about the year 1500, when Francisco d'Almeida, Viceroy of India, landing at Table Bay, was killed, with about seventy of his followers, in a scuffle with the natives. They were afterwards frequently visited by navigators from different countries; but no authentic account reached Europe respecting them until the Dutch settled in the Cape of Good Hope in the middle of the 17th century. The H. were then much more numerous than at present, but upon becoming addicted to rum and brandy, their numbers diminished gradually. Many of the tribes parted with their flocks and herds to procure the fire-water, and eventually they became the absolute slaves of the Dutch settlers or Boers. From this condition they have been delivered by the enlightened and humane policy of the British government; and as free labourers they make excellent herdsmen and drovers. Their number at present is thought to amount to about fifteen thousand, and from that to twenty thousand, not including those who in all probability may be found dwelling more in the interior. Of the Bushmen, no numerical estimate has been formed. They are widly scattered throughout the English settlements, but their numbers must be very small, while their wretched and degraded habits are such that it is thought they will soon become utterly extinct.
The muzzle is not so sharp as in greyhounds, nor is the form so slender. The ears are large and pendulous. Some varieties have rough, and some have smooth hair. The rough-haired varieties are generally those which exhibit the most perfect domestication, and in which the attachment to man is closest. True hounds are figured in ancient Egyptian paintings and sculptures. It is believed that all the best varieties were introduced into Europe in comparatively recent times from the East.

HOUNDS, in point of law, render the person who keeps them liable to the dog-tax—viz., twelve shillings each—unless compounded for; but a person who follows the hounds, i.e., goes out hunting with them, does not require a game licence. Though such a person, however, is not punishable summarily by a magistrate for an illegal trespass when following the hounds on a stranger's lands, yet he is liable to an action at law for the trespass, except only in the case of fox-hunting, which to this extent may be called a privileged pursuit, at least in England. In Scotland, fox-hunting is not allowed as an excuse for a trespass; and in England and Ireland, even in following the fox-hounds, no more damage is to be done than what is absolutely necessary.

HOUND'S-TONGUE (Cynoglossum officinale), a genus of plants of the natural order Boraginace, of which there are many species, all of a coarse appearance, with small flowers. The Common H. (C. officinale) is a native of Europe, Asia, Africa, and North America; not uncommon in some parts of Britain, especially near the sea-coast. It has soft downy leaves, of a dull-green colour, purplish-red flowers, and a stem about two feet high. Its colour is very disagreeable. The root was formerly administered in scrofula, dysentery, &c., and is said to be anodyne. It is also one of the pretended specifics for serpent-bites and hydrophobia.

HOUSINGLOW, a small town of England, in the county of Middlesex, consists of a single street, stretching along the Great Western Road from London, from which it is distant ten miles west. Its church, a modern building in the Italian style, is surmounted by twelve small spires and a belfry. The numerous inns and posting-houses of H. were busy and prosperous till the opening of the railways to Southampton and Bath. Previous to that event, its posting business was as extensive as that of almost any town in England. About 800 horses were then maintained here, and about 183 coaches while 500 coaches passed through the village daily.

The Heath, which till the present century was notorious as the scene of frequent highway robberies, is now in great part enclosed. Numerous villas have risen up around the town. On the Heath are extensive gunpowder mills. Pop. (1861) 6632.

HOURLY, a measure of time equal to one-twelfth of a day. The division of the day into hours seems to have been known to the Babylonians and Egyptians, from whom, first the Greeks, and then the Romans derived it. But their scheme of division extended only to twelve, viz. (utta, the sun was above the horizon), which they divided into twelve parts. The consequence of this was that the hour constantly varied in length. This system was introduced into Rome by L. Papirius Cursor about 263 B.C., and during the Punic Wars, the Romans adopted the division of the night also into twelve parts. This system continued till about the end of the 4th c., when the present system was adopted. In the British Empire and most countries, the day is reckoned from midnight to mid-day 12 hours, and mid-day to midnight 12 hours. In Italy, the day is reckoned from sunset to sunset. Astronomers reckon from mid-day (on the previous day) to mid-day, counting from 1 to 24.

HOÛRA, a town on the right or west bank of the Hooghly, stands within the limits of the Twenty-four Pergunnahs, in lat. 22° 36' N., and long. 88° 27' E. It is directly opposite to Calcutta, and is the commercial and manufacturing centre of Bengal. The river Hooghly rises in the town, and is navigable for both passenger and goods boats. It is about 73 miles long, and has a fall of 23 feet. It flows through the Hooghly delta, which is about 800 miles in length. The delta is divided into numerous branches, and is a vast tract of salt marshes and backwater. The town is celebrated for its fine produce of rice, and for its shipbuilding industry. The climate is very warm, and the rains are excessive. The town is connected with Calcutta by ferries, and is an important centre of trade.

HOÛRGLASS, an instrument for measuring intervals of time. It is made of glass, and consists of two bulbs united by a narrow neck; one of the bulbs is nearly filled with dry sand, fine enough to run freely through the orifice in the neck, and the quantity of sand is just as much as can run through the orifice in an hour, if the instrument is to be an hour-glass; in a minute, if a minute-glass, &c. The obvious defects of this instrument are the expansion or contraction of the orifice produced by heat or cold, and the variations in the dryness of the sand, all of which produce deviations from the true measurement of the time. The hour-glass was almost universally employed in churches during the 16th c., and continued in use till about fifty years ago. In several of the churches in England, hour-glass stands of elegant workmanship are still to be seen.

HOUSTON, a river of New England, which rises in Massachusetts, and flows southwardly through Connecticut into Long Island Sound. Its length is about 130 miles, through a picturesque country, and its numerous falls afford water-power to many manufacturing villages. For forty miles its course is followed by the Housatonic Railway.

HOUSE, in point of law, is an Englishman's castle, though not a Scotchman's. In other words, when a man shuts himself up in his own house, no bailiff can break open the door to arrest him, or
seize his goods for debt in England or Ireland, and no court can give a bailiff such power; in Scotland, however, even a man's own house is no protection, for the sheriff can get out the constable armed with a warrant, or in some cases without, to break into the house and arrest him.

In England, therefore, if a person can manage to procure supplies from without, he can fortify himself against the enemy for any length of time; but though it is not competent for the bailiff to break open the outer-door by force, yet every trick or stratagem is fair in order to effect a peaceable entry, and once in, he cannot be turned out. Where the party is charged with a criminal offence, a constable armed with a warrant, or in some cases without, is entitled to break into the house and arrest him, both in England and Scotland. A man is entitled also to defend his house against trespassers and thieves, using no greater force than is necessary; and if necessary in that sense, he may even kill the intruder, though very strong circumstances are required to justify this. He may also put spring-guns on the premises.

In Scotland, a peculiar name is given to the offence of feloniously assaulting a man in his own house, called Haimaunck (q. v.), though in England it is not singled out by a separate name; yet all offences committed in a house are generally punished more severely. Housebreaking is a technical name in Scotland, but in England is a popular phrase, the legal term being larceny or robbery in a dwelling-house, or burglary, according to the circumstances.

HOUSE OF COMMONS. See PARLIAMENT.

HOUSE OF CORRECTION, a jail which is not under the ordinary charge of the sheriff, but is governed by a keeper; it is also sometimes called a Bridewell. These houses were originally intended for the detention of vagrants and convicted persons, and compelling these to work; but their purpose is now extended in England. Every county, and most cities and towns, must have one. The persons who may be committed to them are prisoners convicted of felony, or misdemeanour; persons committed on charge or suspicion of felony, or of misdemeanour; and vagrants. And generally, any justice may commit to the House of Correction persons awaiting their trial, and persons convicted of small offences. The prisoners are classified, and the courts are more generally defined by 4 Geo. IV. c. 64, 5 and 6 Will. IV. c. 38. In Scotland, the regulation of prisons is transferred to a Board of Directors of Prisons in Scotland, 7 and 8 Vict. c. 34, 14 and 15 Vict. c. 27.

HOUSE OF LORDS. See PARLIAMENT.

HOUSEBOATS, in English Law, the right which a tenant has to cut wood on the land to repair the house, often called Estovers.

HOUSEBREAKING. See HOUSE.

HOUSEBURNING, a crime in Scotland, generally called Arson in England.

HOUSE-DOVES, in the Law of England, are protected like domesticated animals, and the taking of them is in general larceny; and if the offence of larceny cannot be made out, then a magistrate may inflict a penalty of £2, over and above the value of the bird (34 and 35 Vict. c. 90, s. 23). In Scotland, it is also theft to break into dove-cotes. But there is no summary redress for the lesser offences.

HOUSE-FLY (Musca domestica), an insect too well known to need description, and remarkable for its extensive distribution both in the Old and in the New World. It belongs to the vast dipteron family Muscidae. The maggots live in moist dung, in heaps of rotting vegetables, &c. When house-flies become annoying, various expedients are resorted to for killing them, as trapping in glasses partially filled with some sweet viscid fluid, or by pieces of paper covered with a mixture of sweet and poisonous substances. Sweet substances, however, attract flies into a room, so that the benefit of fly-traps is often doubtful; and care must be taken that the poisons used do not endanger the lives of children or others. Quassia is safe enough in this respect, and very fatal to flies. In addition to what has been said in the article DIPTERA concerning the power which many insects possess of walking on perpendicular walls, ceilings, &c., it may here be mentioned that, according to the observations of Mr Hepworth, who has carefully investigated this subject, although the membranes discs (palpi) on the foot of a fly are incapable of being used as suckers, yet the hairs with which they are thickly beset, are terminated by minute discs, which probably are so used. At the same time, these minute discs appear to exude a liquid, not viscid, which probably serves to make the adhesion more perfect.

The proboscis of the H. is a very interesting microscopic object. It is chiefly formed by an extraordinary development of the tonguet or linguula, the upper part of the under lip (labium), but with this are combined lancets formed of the metamorphosed maxillae. (For these, see COLEOPTERA.) The lobes of the linguula are much enlarged and flaky. They are surrounded by rough hairs, to aid in scraping or tearing delicate surfaces. There are many rows of these hairs on each lobe. In using its proboscis to feed on dry substances, as sugar, the fly moistens them with a liquid which may be regarded as saliva, so as to fit them for suctorial action. To aid in this suctorial action, the muscles of the lobes of the linguula are disposed in a spiral form.

HOUSEHOLD TROOPS are those troops whose especial duty it is to attend the soveregn, and to guard the metropolis. These forces comprise three regiments of cavalry—the 1st and 2d Life-guards, and the
regiments of Foot-guards (which include seven battalions), the Grenadier, Coldstream, and Scots Fusilier Guards. The cost of these corps, for pay and allowances only, reaches the sum of £280,000 a year; and they number in all ranks 1317 cavalry and 6306 infantry, who are justly held to be the lower of the British army.

HOUSE-LEEK (Sempervireum), a genus of plants

House-Leek (Sempervireum tectorum).

of the natural order Crassulaceae, having a calyx of 6-20 sepals, the petals equal in number to the sepals, and inserted into the base of the calyx; the leaves generally very succulent, and forming close rosettes. The Common H., or Cyphel (S. tectorum), called Pous or Pounz in Scotland, and in some countries Jupiter’s Beard, grows wild on the rocks of the Alps, but has long been common in almost every part of Europe, planted on walls, roofs of cottages, &c. It sends up leafy flowering stems of 6-12 inches in height, bearing branches of pale-red star-like flowers, equally curious and beautiful. The leaves cut or bruised, and applied to burns, afford immediate relief; as they do also in stings of bees or wasps; and they are a beneficial application to ulcers and inflamed sores. They were formerly in high esteem as a remedy for fevers and other diseases, and an edict of Charlemagne contributed greatly to the extensive distribution of the plant. The edict is in these words: Li habeat quiunque supra domum eum Jovis barbam (And let everybody have the Jupiter’s beard on his house).—Other species possess similar properties. S. soboliferum, with yellowish-green flowers, is very frequently planted on walls in Germany. Some of the species, natives of the south of Europe, Canary Islands, &c., are shrubby; others are common greenhouse plants.

HOUSEMAID’S KNEE is the term commonly applied to an acute inflammation of the burna or sac that intervenes between the patella, or knee-pan, and the skin. Housemaids are especially liable to it from their kneeling on hard damp stones. It causes considerable pain, swelling, and febrile disturbance. The only disease for which it can be mistaken is acute inflammation of the synovial membrane lining the cavity of the joint; but in this disease, the patella is thrown forwards, and the swelling is at the sides, while in housemaid’s knee, the swelling is very superficial, and is in front of the patella.

The treatment consists essentially in the means usually employed to combat inflammation; viz., rest, fomentations, and purgatives; if suppuration take place, the sac must be freely opened, and the pus evacuated.

HOUSE-RENTS, in Scotland, when the lease is verbal, prescribe in three years—i.e., no action can be maintained after that time; but in England an action can be brought within six years. See LANDLORD AND TENANT.

HOUSNA, or, according to Dr Barth, HAUZA, a district of Africa in Sudan, forming a portion of the empire of Sokoto (q. v.). The name, however, is used to designate rather the race inhabiting the district, and the language which there prevails, than to mark any distinct political division. H. Proper comprises seven states. The country of the H. is very beautiful, and the inhabitants lively, spirited, and industrious.—See Barth’s Travels and Discoveries in North and Central Africa.

HOUSTON, a city in Texas, United States of America, at the head of steam-boat navigation on Buffalo Bayou, 45 miles from its mouth in Galveston Bay, and 80 miles from Galveston. It has iron foundries, machine-shops, and cotton-presses, and exports cotton, sugar, and agricultural products. Pop. in 1860, 5000.

HOUSTON, SAM, general and ex-president of Texas, was born near Lexington, Rockbridge Co., Virginia, March 2, 1793; enlisted as a common soldier in the war of 1812; was chosen ensign, and fought under Jackson with a courage that won him lasting friendship. In 1823, he was chosen member of congress, and in 1827, governor of Tennessee. In January 1829, he married the daughter of an ex-governor; and in the following April, for reasons never made public, abandoned wife, country, and civilisation, was adopted as a son by the chief of the Cherokee nation, beyond the Mississippi, and was formally admitted as a chief. In 1832, he went to Washington, and procured the removal of several United States Indian agents, on charges of fraud, but got into personal difficulties with their friends. The Texan war offered a new field to his ambition. H. was made commander-in-chief. The Americans at first sustained some severe defeats, and H. was obliged to retreat before the Mexicans under Santa-Anna for nearly 300 miles, but suddenly turning on his pursuers, H. fought the remarkable and decisive battle of San Jacinto on the 21st April, at one blow annihilated the Mexican army, and achieved the independence of Texas. The hero of San Jacinto was elected first president of Texas, and re-elected in 1841, and on the annexation of Texas to the United States in 1845, sent to the national senate, where he remained until 1859, when he retired, and was elected governor of Texas. He opposed secession, but retired to private life when he found that opposition was fruitless.

HOVEN, or distention of the rumen or first stomach with gas, is a common complaint among cattle and sheep, and results from the eating of food to which the animal has been accustomed, from wet clover or vetches, or from any easily fermentable food. Relief generally follows walking exercise, friction on the belly, and a dose of any ordinary stimulant, which for a cow may consist of a couple of ounces of turpentine, whisky, ether, or ginger, to which should also be added, in order to clear the bowels, one or two grains of salt, or a pint of oil or a pound of salts. A fourth or fifth of these quantities will suffice for sheep. The introduction of the probang, with the small end downwards, allows the escape of gas when there is little food in the stomach. If simple remedies fail, the breathing become distressed, and the animal stupid; the gas may with safety be allowed to escape by an external opening made at a point
Howard.

intermediate between the last rib, the lumbar vertebra, and the prominence of the haunch, either with a camisa and trochar, or a large pocket or table knife. For several days after an attack of hovery weakness, organ is apt to be easily deranged, and the animal must have soft and digestible food, and an occasional dose of simple laxative medicine.

Howard. The noble House of H. has stood for many ages upon the firmest of all the British and Eminent Poles, under Edward I. and Edward II., though Dugdale incidently mentions a tradition that their name is of Saxon origin, and derived either from an eminent office under the crown before the Conquest, or from Hereward, the leader of those forces which for a time defied the issue of Ely so valiantly against William the Conqueror. Whether this be as it may, it is certain that Sir John H., the grandson of the above-mentioned judge, was not only admiral and captain of the king's navy in the north of England, but in the defence of Norfolk, in which county he held extensive property, which was subsequently increased by the marriage of his grandson, Sir Robert, with the co-heiress of the ancient and noble House of Mowbray, Dukes of Norfolk. The only son of this union was Sir John H., one of the leading supporters of the House of York, who, having gained early distinction in the French wars of Henry VI., was constituted by Edward IV. constable of the important castle of Norwich, and sheriff of Norfolk and Suffolk. He subsequently became receiver of the royal household, obtained a grant of the whole benefit that should accrue to the king by coinage of money in the City and Tower of London, and elsewhere in England; and further, was raised to the peerage as Lord Howard and Duke of Norfolk.

We find him in 1470 made captain-general of the king's forces at sea, and he was most strenuous in that capacity in his resistance to the House of Lancaster. Finally, he was created Earl Marshall of England, an honorary distinction still borne by his descendants, and in 1484 was constituted Lord Admiral of England, Ireland, and Aquitaine. He fell next year, however, on Bosworth Field, and, after his death, his honours were attained, as also were those of his son Thomas, who had been created Earl of Surrey. The latter, however, after suffering three years of imprisonment in the Tower of London, obtained a reversal of his own and his father's attainders, and being restored to his honours accordingly, became distinguished as a general, and is more particularly celebrated in history for his defeat of the Scotch at Flodden in 1513. His son Thomas, third Duke of Norfolk, was attainted by Henry VIII., though afterwards restored in blood, and by his marriage with a daughter of King Edward IV., became the father of the ill-fated and accomplished Earl of Surrey, whose execution was the ruin of the House of York, in many acts of tyranny which disgraced the memory of Henry VIII. "Eminent as a statesman, a warrior, and a poet, Surrey is thus described by Sir Egerton Brydges: 'Excellent in arts and in arms; a man of learning, a genius, and a hero; of a generous temper and a refined mind, he united all the gallantry and unbroken spirit of a rude age with all the elegance and grace of a polished era. With the greatest splendour of descent, in possession of the highest honours and unbounded wealth, he relaxed not his efforts to deserve distinction by his personal worth. Conspicuous in the rough exercises of tilts and of tournaments, and commanding armies with skill and bravery in expeditious against the armies and in the open field; he, still found time, at a period when our literature was rude and leas, to cultivate his mind with all the exquisite spirit of the choicest models of Greece and Rome, to catch the excellence of the revived muses of Italy, and to compose in a form of which, in simplicity, perspicuity, graceful ornament, and just and natural thought, exhibit a shining contrast to the works of his predecessors, and an example which his successors long attempted in vain to follow.'"
great earthquake at Lisbon, urged by motives of benevolence, as well as of curiosity, he set sail for that city. On this voyage his vessel was taken by a French privateer, and he was carried into the interior, where he suffered imprisonment for some time. The hardships which he here underwent, combined with the knowledge of prisons and the miseries of prison-life which he acquired as a county sheriff in 1772 and afterwards, determined him to devote himself to prison reform. His life hereafter was spent in traveling all over the United Kingdom and the continent, in which he visited the principal prisons and hospitals.

The chief work in An Account of the Lazarettos in Europe, etc., with Remarks on the Present State of the Prisons in Great Britain and Ireland (1780).

He died January 20, 1790, at Kheresin, in the south of Russia, from having caught infection from a fevered patient for whom he had prescribed. The fame of H. is peculiar. He is remembered not so much for his talents as for that devotion to his suffering fellow-men, in which he expended his fortune and his life.

HOWE, EARL (Richard Howe), British admiral, was the second son of Emanuel Scrope, second Viscount Scrope of the Irish peerage, born in 1723, and educated at Eton. Having a boisterous passion for the sea, he left Eton at 14, and went to the South Seas in the squadron under Anson. He was with Admiral Vernon in 1748, and at the time of the Spanish Armada and in the campaign of the Baltimore sloop, took part in the siege of Fort William. He also, with another vessel, beat off two French ships convoying troops and ammunition to the Pretender, to which they had been posted. In 1755, his ship, the Dunkirk, captured the Alcide, a French 64, off Newfoundland. He next served under Sir E. Hawke in the expedition against Rochefort. He was ordered to attack the fort on the island of Anville with his ships the Magnanime, compelled it to surrender after an hour's cannonade, and achieved the only material success which attended the expedition. He was commodore of the squadron which sailed in 1758 for St Malo. The troops were landed and re-embarked without loss, after destroying all the magazines and shipping in the port, to the number of 120 sail. In the same year he took Cherbourg. Nearly 200 pieces of iron cannon and mortars were here rendered unserviceable; the lost How chargers and the How shot kept the celebrated basin was destroyed, and 27 ships and vessels were burned or sunk. A second attack upon St Malo was less successful. The French troops assembled in force at the Bay of St Malo, and it was only by the intrepidity of H., who went in his own barge into the centre of the enemy's fire, that the re-embarkation of the rear-guard was effected, with great loss of life. In 1758, he succeeded to the Irish title of Viscount on the death of his brother, the brigadier-general, who was killed before Ticonderago. He took part in the defeat of the fleet under the Marquis de Conflans, and captured the Hero, 74 guns. In 1760, he was made colonel of the Chatham division, and afterwards a Lord of the Admiralty, and Treasurer of the Navy. In 1776, he commanded a fleet on the American coast, when the conquest of New York, Rhode Island, and Philadelphia, and the occupation of the French ships on the Delaware, within the reach of a naval force, testified to his skill and energy. In 1778, he defended the American coast against superior naval force under D'Eas'tain. He was made a viscount of Great Britain in 1782, and sent out with a fleet to relie of Gibraltar. He succeeded in disembarking troops, ammunition, and supplies, and then offered battle to the combined fleets of France and Spain, which declined an engagement. He was made First Lord of the Admiralty in 1783, and received an English earldom in 1788. When war with France broke out in 1793, he took the command of the Channel fleet, and next year gained the victory which will long be known as that of 'the glorious first of June.' The French fleet consisted of 26 ships of the line, and the English of 25. H., in his flag-ship, the Queen Charlotte, engaged in the Bay of Biscay, off Ushant, the French admiral, who in less than an hour before the battle had crowded all the sail he could carry, followed by as many of his ships as could get away. The English captured two ships of eighty guns, and four seventy-fours; another seventy-four sank immediately after she was taken possession of. London was illuminated three nights in honour of the victory. The thanks of parliament were voted to Howe. George III. visited him on board the Queen Charlotte, gave him a sword, and made him a Knight of the Garter. His last service was in bringing back the mutinous wamen at Portsmouth to order and duty in 1797. He died August 5, 1799, aged 74, leaving a name high in the rôle of English naval worthies.

HOWE, JOHN, who has been called the Platonic Parson, was born 17th May 1630, at Loughborough, in Leicestershire, to the living of which parish his father had been presented by Lawrence Holden who died both at Cambridge and Oxford, and after preaching for some time at Winwick, in Lancashire, and Great Torrington, in Devonshire, he was appointed domestic chaplain to Cromwell in 1666, in which difficult situation he was as much exposed alike from the Civil as even from the enemies of his party. At the Restoration, he returned to Torrington, where the position he had held during the Commonwealth made him an object of close suspicion to the government. The Act of Uniformity, however, ejected him from his parish, 24th August 1662, and he wandered about preaching in secret till 1671, when he was invited by Lord Massarne, of Antrim Castle, in Ireland, to become his domestic chaplain. Enjoying there the friendship of the bishop of that diocese, and liberty to preach in all the churches under his jurisdiction, he wrote his Vanity of Men as Mortal, and began his greatest work, The Good Man the Living Temple of God (1675—1679), which occupies one of the highest places in Puritan theology. In 1675, he was called to be pastor of the dissenting congregation in Silver Street, London, and went thither in the beginning of 1676. In 1677 he published, at the request of Sir Bernard de Gomme, The Celestial Breath of God's Presence of the Sins of Men with the Wisdom of His Counsel and Exhortations; in 1681, Thoughts for the Morrow; in 1682, Self-dedication; in 1683, Union among Protestants; and in 1684, The Redeemer's Tears wept over Lost Souls. In 1683, he was invited by Lord Wharton to travel with him on the continent; and after visiting the principal cities, he resolved, owing to the state of England, to settle for a time at Utrecht, where he was permitted to several interviews with the Prince of Orange. In 1687, the Declaration for Liberty of Conscience induced him to return to England, and at the Revolution next year he headed the deputation of dissenting clergymen who brought their address to the throne. Besides smaller works, he published, in 1693, Carnality of Religious Contention; in 1694—1695, several treatises on the Trinity; in 1699, The Redeemer's Dominion over the Invisible World; and he continued writing till 1705, when he published Patience in Expectation of Future Blessness. He died 2d April 1706. See Henry Rogers's Life and Character of John Howe, with an Analysis of his Writings.

HOWE, SAMUEL Gridley, M.D., an American
HOWNT—HOY.

HOWNTHERS are guns which came into use early in the history of field-artillery, as portable instruments for discharging shell into a hostile force. As, for this purpose, no great range was necessary, a small charge of powder sufficed; and the howitzer could be made, in proportion to its large bore, extremely light. It combines in some degree the accuracy of a cannon with the calibre of a mortar; and while equally effective at short ranges, is far more portable than either. That the powder, on its expansion, may act with full force on the shell, it is confined in a hemispherical chamber of smaller diameter than the rest of the bore, the mouth of which is completely closed by the shell when rammed home. The Coehorn howitzer, much used in India for mountain-service, is a small gun, light enough to be borne by a horse up hilly defiles, &c.

HOWLER, HOWLING MONKEY, or STENTOR (Mycetes), Aliasvate of the French, a genus of American monkeys, remarkable for the dilatation of the Hyoid (q. v.) bone into a hollow drum, which communicates with the larynx, makes a conspicuous external swelling of the throat, and gives prodigious power to the voice, enabling these animals to emit hideous sounds, which are heard miles away, and to which all their names refer. They live chiefly among the branches of trees, and take extraordinary leaps from one to another, taking hold by the tail as readily as by the hands, and often swinging by it alone. They are gregarious, and unite their voices in concert, so as to produce a most deafening noise. The monkeys of this genus are regarded as in their low intelligence and their fierceness of disposition American representatives of the baboons, whilst in many of their habits they move nearly accord with the gibbons of the Old World. They inhabit the north-eastern parts of South America. They are the largest monkeys in the New World. There are not many species.

HOWTH, a small peninsula on the east coast of Ireland, forms the north shore of the Bay of Dublin, and is two and a half miles long by about two miles broad, with an area of about 2000 acres. H. is connected with the mainland by a low and narrow isthmus, and its insular appearance greatly enhances the picturesque effect of Dublin Bay.

HOY, a small vessel differing little, if at all, from the sloop or smack. Its ordinary employment is in carrying goods or passengers coastwise from one place to another, and particularly in inlets. *
HUBER, FRANCOIS, a Swiss naturalist, was born at Geneva, July 2, 1750. At an early age he lost his eyesight, and some years after this, married a Mademoiselle Lullin, by whose assistance, and that of an intelligent domestic, named Burmens, he made a vast variety of original and important observations on the habits of bees, which did much to correct the errors and imperfections of previous writers.

H.'s first work was entitled Lettres a Ch. Bonnet (1782). It was reprinted in 1796, and again in 1814, under the title of Nouvelles Observations sur les Abeilles. In his latter years, H. derived important aid in his studies from his son Pierre (born 1777, died 1840), the author of a valuable treatise on the Habits of Ants, and of several able memoirs relating to Zoology and Meteorology, which are to be found in the Mem. Soc. Genève, between the years 1821 and 1830. H. died at Lausanne, 21st December 1851.

HÜBNER, RUD. JUL. BENN., one of the most eminent painters of the modern German school, was born at Oels, in Silesia, in 1806, and first attracted attention by his picture of 'Ruth and Boaz.' In 1839, he settled at Dresden, where he has been a professor since 1841. His principal productions are "Samson overcoming the Pillar in the Temple," 'The Departure of Naomi,' 'Christ and the Evangelists,' 'Job and his Friends,' 'The Lovers of the Canticles,' 'Happiness and Sleep,' 'Christ in the midst of the People,' 'The Fisherman' (from the ballad of Goethe), and 'The Golden Age.' H. belongs, as the character of his works shews, to the great historic and religious school of German art whose principal seat is Düsseldorf.

HUC, ÉVARISTE RENÉ, a distinguished missionary and traveller, was born at Toulouse, August 1, 1813. He was educated in his native city, and about his 24th year he entered the missionary congregation of the Lazarist Fathers, and received holy orders at Paris in the year 1839. Almost immediately after his ordination, he joined the missionary expedition of his order to China. After he had spent about three years of missionary life in the northern districts of China, the new apostolic vicariate of Mongolia was founded, and H., in company with a priest of the same congregation, Père Gabet, and a Swiss native, Gabel, who had accompanied him, took to explore the new district, and to ascertain, for the guidance of the mission, its extent and its missionary capabilities. After a few months' study, in the province of Tarts, they opened the missionary station, north of the Great Wall, called Si-wang, towards the close of 1844; and after a journey of excessive hardship over the high tablelands of Tartary, they took up their quarters for some months in one of the Lamaseries, or Tartar monasteries. Having here become familiarised in some degree with the Tibetan language, they succeeded in making their way, in January 1846, to H'lasa, the capital of Tibet, and the residence of the Grand Lama; but scarcely had they settled in that city, when an order for their immediate expulsion from the country was obtained from the Lama by the Chinese resident in H'lasa. They were not permitted to resume their route homewards, but having been put in charge of a Chinese official, were carried back a journey of nearly 2000 miles to the extreme south, and arrived in October 1846 at Macao, where they were subjected to a tedious trial by the Chinese authorities. The end of 1846, and part of 1847, were permitted to return to the missionary station of Si-wang, from which they had originally taken their departure. H.'s health having been completely broken down, he sailed from Macao in the beginning of January 1849, and in the autumn of
the same year reached his native city of Toulouse. In the following year he returned to Paris, where he published Souvenirs d'un Voyage dans la Tartarie, le Tibet, et la Chine pendant les Années 1844—1845 (Paris, 1852). This work was followed, in parliament by his"." But the railway mania was at its height, a statute to H. as proposed, and measures were put down for £2,000,000; but before the money could be collected, the popularity of the Railway Bill" was on the wane. His connection with the Eastern Counties Railway led to some exposures. The accounts had been 'exposed,' matters had been 'made pleasant,' and dividends had been paid out of capital. Suspicious were excited in regard to his direction of other companies, shares fell, the bubble burst, the railway monarch was deposed, and encountered nothing but invective from quarters which had pursued his획은). Every board-room was closed against him, and his suddenly acquired gains were almost swept away. The constituency of Sunderland, however, continued to sit as his representative until March 1859. He has since resided abroad, in comparatively narrow circumstances.

HUCKABACK. A very coarse kind of linen-cloth, figured somewhat like damask; it is usually employed for common towelling.

HUDDERSFIELD, a parliamentary borough and important manufacturing and market town of England, in the West Riding of Yorkshire, is situated in the midst of a fertile district, on an activity rising from the left bank of the Colne, 16 miles south-west of Leeds, and about 25 miles north-east of Manchester. It is remarkably regular, is well built and drained, and very healthy. Upon the Holme and the Stour, which unite in the town, numerous mills have been erected for the manufacture of woollen fabrics, and for fulling and washing the goods manufactured. H. stands in the centre of a district rich in coal, and its natural advantages are enhanced by its direct connection with the principal seats of manufacture in the north of England, by means of the London and North-Western, Lancashire and Yorkshire, and Manchester, Sheffield, and Lincolnshire railways. Among its churches, several are noteworthy in an architectural view. It has a proprietary college, now in connection with the London University; a collegiate school, and many other institutions; a navigable cloth-hall 2640 feet in circumference, attended by upwards of 600 cloth-merchants each market-day (Tuesday and Friday): an infirmary; and in the vicinity the Lockwood Spa Baths, where the water is strongly sulphureous. H. is the chief seat in the north of England of what is called the 'fancy trade,' comprising shawls, waistcoatings, flannelings, &c., of the most elegant patterns and the finest fabric: it also carries on extensive manufactures of narrow and broad woolen fabrics, kerseymers, serge, and cords. It is connected by canals with the Mersey and the Humber. The parliamentary borough sends one member to the House of Commons. Pop. (1881) 39,574.

HUDSON. GEORGE, English railway director and speculator, was born in 1799, and apprenticed to a linen-dyer in the city of York, where he subsequently carried on business for himself. He took an early share in railway speculation, and was appointed a director of the North Midland Company. His plans of management were carried out, schemes of railway annexation and extension were undertaken, embarrassed lines were relieved, and rivals were subdued. He was elevated into the dictatorship of railway speculation; everything he touched turned into gold; and H. was everywhere known as 'the Railway King.' The shares of the lines with which he consented to become connected went up, and he said to have made £100,000 in one day. He bought large estates; was three times elected to Parliament, to which he was returned, in 1841, as representative of Sunderland; and found his acquaintance courted by persons of the highest rank. When the railway mania was at its height, a statute to H. was proposed, and measures were put down for £2,000,000; but before the money could be collected, the popularity of the Railway Bill" was on the wane. His connection with the Eastern Counties Railway led to some exposures. The accounts had been 'exposed,' matters had been 'made pleasant,' and dividends had been paid out of capital. Suspicious were excited in regard to his direction of other companies, shares fell, the bubble burst, the railway monarch was deposed, and encountered nothing but invective from quarters which had pursued his 획은). Every board-room was closed against him, and his suddenly acquired gains were almost swept away. The constituency of Sunderland, however, continued to sit as his representative until March 1859. He has since resided abroad, in comparatively narrow circumstances.

Hudson, Henry, a distinguished navigator. His early history is unknown. He undertook his first voyage for the discovery of a north-east passage in 1607, in a small vessel with ten sailors, but failed in this attempt. In his second voyage in 1608 he reached Nova Zembla. He undertook a third voyage in 1610 from Amsterdam, at the expense of the Dutch East India Company. Giving up all hope of finding a north-east passage, he sailed for Davis's Strait, but encountered an American continent about 44° N. lat., and, steering southwards, discovered the mouth of the river which now bears his name. He sailed upon his last voyage in April 1614, with 23 sailors, and reached Greenland in June. Steering westward, he discovered the strait now known as Hudson's Strait, and passed through it, and entered the great bay, which has received the name of Hudson's Bay. Although very insufficiently supplied with provisions, he adopted the resolution of wintering in these desolate regions, in order to prosecute his discoveries further in the following spring. He proceeded to carry this design into execution, but his provisions became so much exhausted that he was compelled to return. This sailed mutinied, and placed him, with his son and some others who adhered to him, in a small boat, at the mercy of the waves and of the savages. His fate was revealed by one of the conspirators. An expedition was sent from England in quest of him, but no trace of him or of his companions in misfortune was ever discovered.

Hudson, Sir James, K.C.B., diplomatist, is the son of a Yorkshire gentleman, and was born in London in 1810. He was educated at Rugby and Westminster, and subsequently studied at Paris and Rome. He was made private secretary to William IV.; and after the king's death, entered the diplomatic service, and became Secretary at Legation at Washington in 1838, at the Hague in 1842, foreign commissioner to the Viceroy of Bengal, was appointed minister to Rio, but was transferred to Florence in 1851, and to Turin, January 1852. His counsels exercised great influence over the Sardinian government; and the conclusion of a commercial treaty between that country and England, the accession of Sardinia to the treaty of alliance
Hudson—Hudson's Bay Company.

between England and France against Russia, and the despatch of a Sardinian army to the Crimea, were services which procured for him the dignity of K.C.B., and gave further validity to that result which led to the independent and united kingdom of Italy, demanded the watchful vigilance, and sometimes the active interference, of the British minister (now ambassador) at the court of Turin. He has never forgotten that he is the minister and representative of a constitutional government, which sympathises with the aspirations of the Italians for national independence, and which has therefore the privilege to warn and counsel as well as to animate. His devotion to course has not escaped the anannovation of the partisans of things as they were; but it has commanded the approbation of the vast majority of his countrymen.

Hudson, a city of New York, United States, America, on the east bank of the Hudson river; at the head of ship navigation, 116 miles north of New York, and 29 miles south of Albany. It is a beautifully situated and well-built city, a point of entry, and formerly had a large amount of shipping engaged in the foreign trade and the whale-fisheries. It is now chiefly engaged in the manufacture of cloth and clothing, and in the export of agricultural staples. It has a fine courthouse, eleven churches, public library, orphan asylum, and three newspaper-offices. Pop. in 1860, 7282.

Hudson, a river in New York, United States, America, and one of the most beautiful and important rivers in the world. Its source rises in the Adirondac mountains, 4000 feet above the level of the sea, and its head-streams are the outlets of many mountain lakes, in the northeastern portion of the state. At Glenn's Falls, it has a fall of 50 feet, and soon afterwards a southern course; then a straight line to its mouth, at New York city. At Troy, 151 miles from its mouth, it is affected by the tide, and becomes a broad deep river, having a width of from 200 to 700 yards, and deep enough for the largest river steam-boats, and for ships to Hudson, 116 miles. At Newburg, 61 miles from New York, the river enters the highlands, which rise abruptly from the water to the height of 1200-1600 feet. Here the scenery is of great beauty and grandeur, and is admired by all travellers. Several of the heights are crowned with the ruins of fortifications, built to prevent the passage of British ships in the War of Independence. Here was the scene of Arnold's retreat, and the sad fate of Major André. Emerging from the highlands, the river widens into a broad expanse called the Tappan Zee. Below, on the west bank, on the New Jersey shore, rises an almost straight and perpendicular wall of trap rock, from the river's brink, to a height of 300 to 500 feet, called the Pallisades, extending 15 miles to the upper portion of the city of New York. The river is here from one to two miles wide, and here it falls into New York harbor. Its average length is about 300 miles, and its principal tributaries are the Housatonic, Mohawk, Walkill, and Croton. The steam-boats which ply on the H. are among the finest and fastest in the world. Steamers more than 1000 feet long are fitted up with great luxury, and attain a speed of 23 to 24 miles an hour. The Hudson River Railway runs along the margin of the river on the east bank, to Albany. By this river, and the Erie Canal, and several railways, New York is connected with the great lakes and the west. The river is named from the English navigator who discovered it, 1609. The first successful experiment in steam-boat navigation was made on this river by Robert Fulton in 1807.

Hudson's Bay, a spacious gulf in the north-east section of the American continent, may be regarded as an arm at once of the Arctic Sea, and of the Atlantic Ocean; it communicates by means of a strait, which, besides being boldly bridged for about ten months of the year, isiset, even during its brief period of navigation, by detached fies and bogs of ice. The eastern portion of this outlet is broken up into two branches, offsets of Davis' Strait, the more northerly bearing the name of Frobisher, and the more southerly that of Hudson. It is fully 400 miles long, and averages at least 100 miles in width. With the Arctic Sea, again, H. B. is connected by channels, which, notwithstanding the comparative lowness of their latitude, have proved far less practicable than the Arctic Sea itself, never having been navigated throughout; but it is only within these twenty-five years that this hopeless result has been definitively accepted by the world. H. B., taken in its narrowest sense, extends in N. lat. from 61° to 62½, and in W. long. from 76½ to 95. When compared with the extensive regions between the eastern side of the Atlantic, the shores of H. B. possess a singularly inhospitable climate. At York Factory, lying nearly in the latitude of Aberdeen, the finest weather of summer is liable to a wintry temperature through a month of the wind; and the most southerly extremity of the gulf is beset for months by snow at the very season when the Faroe Islands, stretching as far north as the parallel of its opposite end, yield available pasture to sheep and cattle.

Though H. B. is not particularly remarkable for the extent of its drainage, yet towards the south and west its basin meets at once the waters of the St Lawrence, the Mississippi, and the Mackenzie. Its largest feeder, the Nelson, fills perhaps a full half of the area, touching the Rocky Mountains on the west, embracing Rainy Lake on the east, and considerably overlapping the international boundary on the south.

Hudson's Bay Company, a corporation erected, in 1670, by Charles II., primarily consisted of Prince Rupert, the king's cousin, and certain specified associates. It was invested with the absolute proprietary, navigation, and exclusive trade of a undefined territory, which, under the name of Rupert's Land, comprised all the regions discovered, or to be discovered, within the entrance of Hudson's Strait. Rupert's Land was essentially the mouth of Hudson's Bay, and all the dependencies of England, being held to embrace all the lands that poured water into Hudson's Bay or Hudson's Strait. For more than a century, however, the grantees confined themselves to the coast. About the period of the formation of the American republic, their advance into the interior was accelerated, if not occasioned, by the more mature development of an ancient rivalry. From about the middle of the 17th c.—an epoch antecedent to the charter—New France, besides stretching, in name, to the arctic circle, had, in reality, advanced to the shores of Hudson's Bay; and this position of affairs was virtually recognized by that provision of the letters-patent, which exempted from their operation any actual possessions of any Christian prince or state. Though the claims of France, after being confirmed in 1697 by the treaty of Ryswick, were at last abandoned in 1713 by the treaty of Utrecht, yet, in point of fact, adventurers from the great lakes, while Canada was still French, had penetrated, in quest of peltry, far up the Saskatchewan towards the Rocky Mountains. Such overland enterprises—interrupted for many years, by the conquest and cession of 1759—1763.
Hudson's Bay Company.

soon came to be prosecuted, with more systematic energy, under English auspices, till in 1783, they led to the formation of the North-west Company of Montreal. After an age of stubborn competition, the Hudson's Bay Company coalesced, in 1821, with its formidable opponent. But the two members of the new partnership had already almost doubled the original field of connection for one association, and soon traversed the basin of the Coppermine; and, finally, twenty years later, the younger one had descended the Mackenzie into the Arctic Sea, and had, through the barrier of the Rocky Mountains, reached the Pacific Ocean. Even in general equity, a body, which now represented all the discoverers, had a peculiar right to the discoveries themselves; but beyond general equity, a secondary provision of the decrees of Charles II., regarding discoveries, at least for the purposes of trade, as accretions to the primary grant. Accordingly, when, in 1821, parliament, in view of the intolerable evils of competition, empowered the crown to issue licences for the Indian Territories—expressly declared to be all the wildernesses of British North America to the west of Rupert's Land—the government exercised this statutory authority in favour of the Hudson's Bay Company, as recent and extended by the coalition. So far as commerce was concerned, there was now no practical difference between Rupert's Land and the Indian Territories, excepting that the charter of the former was perpetual, and the licence of the latter was to be for 20 years at a time, and only at the option of the crown; yet the newly-modified supremacy virtuously ruled the western world, through 75° of long., from Davis's Strait to Mount St Elias, and, through 28° of lat., from the mouth of the Mackenzie to the borders of California.

But these dominions, second, in point of supererogation, to Russia alone among the compact organisations of the world, was gradually diminished. About twenty years after the coalition, Oregon from the borders of California to the parallel of 48° N., which had always been open to Americans by international arrangement, was given up to the United States by the same treaty which sacrificed sections of Canada and New Brunswick; in 1859, the rest of the Cumberland boundary was fixed at the pale of civilisation as the national colonies of Vancouver's Island and British Columbia, and lastly, as the second term of the licence was, in 1859, also permitted to expire without renewal, the Home Office gave the Hudson's Bay Company a license to trade with the Indians and the black man, a license brought within the ambit of the new law, and the Indian Territories contained in the act, under the condition from which the statute of 1821 had been fit to rescue it. In all these cases, excepting, of course, the case of Oregon, the Hudson's Bay Company would appear to have lost rather from privilege than actual influence, retaining, if not a legal monopoly as of old, at least a commercial supremacy on a wider basis. Though the withholding of the licence neither affected, nor professed to affect Rupert's Land, yet between it and the remaining portion of the Indian Territories the difference, so far as Hudson's Bay Company is concerned, is little more than nominal. This result must, to some extent, be regarded as a matter of practical politics; a free company of free colonisation having become part and parcel of our national policy. But one may reasonably doubt how far the virtual abolition of the charter promises to be advantageous. So far as the Indians are concerned, the question is hardly open to discussion. With regard to them, competition, after long and decisive experience, has been already condemned by the supreme legislature of the empire. The opposite side of the other hand, may, in this respect, holdly challenge comparison with the practice of any other portion of North America. Within this range, it may exclusively boast of having neither extinguished nor expatriated the native tribes. Nay, far beyond this negative merit, it has achieved, what has never been elsewhere successfully attempted—the elevation of the descendants of mixed blood as the equals of their white brethren, to the highest degree of civilisation that exists in the country. Yet it may be said, the competition may not fully realise the expectations of either of speculators themselves or of their emisaries. While the latter must gradually lose all reliance for any more steady pursuit, the former, by operating as much against each other as against the Hudson's Bay Company, must at once fritter away the amount of business, and reduce the rate of profit, besides being tempted by the absence of all check to the matter to exhaust, alike the hunter and his game for the sake of present returns; to kill, in a word, the hen that lays the golden eggs. Nor with regard to colonisation does experience lead to much hope of success. Hudson's Bay Company and the former settlers of the Hudson's Bay Company, or their offspring. In very few instances, if in any, have agricultural immigrants gone to Rupert's Land at their own expense; and of the successive bands that have been sent thither by others, such as Lord Selkirk, and the Hudson's Bay Company, and the British government, a very scanty proportion have remained, and those, too, almost constantly on the wing for the south. As a consequence of Charles II., the Hudson's Bay Company possesses certain powers, now practically obsolete, beyond the limits of Rupert's Land, being invested with a jurisdiction over its own servants, which have been exercised in its adjacent wildernesses or on the high seas, and being entitled to make war on any non-Christian prince or people. Its internal constitution, as regulated by the letters-patent, is peculiar in this respect, that without any such graduated restrictions as generally affect similar associations, the influence of a proprietor is precisely proportioned to his number of shares—one vote being attached to every £100 sterling of stock. Further, the body at large is required to act at home through a governor and of the settlers are either retired servants of the Hudson's Bay Company or their offspring. The body at large is required to act at home through a governor and council. As to actual organisation, the local ruler's advisers are mostly such mercantile officers as are above the rank of clerk. These mercantile officers, hence, rare distinguished as with others, such as Lord Selkirk, as agents of the net profits of the concern, a chief factor getting two, and a chief trader one of the eighty-five parts, into which the allotment in question is divided. As a single part, between one year and another, ranges from about £300 to about £500, the total revenue may easily be found to vary from about £335,750 to about £106,250—averaging perhaps about £60,000, so as to yield about £20,000 to the proprietors, and about £20,000 to the wintering partners. This income arises almost entirely from furs; for other articles, such as tallow, oil, feathers, fish, timber, &c., have never been of much account. As nearly all the skins are shipped from Rupert's Land, similar details to the trade through the two ports, Norse Factory and York Factory. See also Indian Territories, Red River Settlement, and Vancouver's Island.

The Hudson's Bay Company naturally excites a retrospective interest, as the last of the great associations that have figured so largely, and, in general, so creditably, in the colonial and commercial annals of England. For further particulars, see Fitzgerald's Examinatio
of the Charter and Proceedings of the Hudson's Bay Company, and Montgomery Martin's Hudson's Bay Company's Territories, and Vancouver's Island, both published in 1849—perhaps the leading works on opposite sides of a much vexed controversy.

HUÉ, the capital of Cochinchina, or, more properly speaking, Annam, in the Gulf of Tonquin, is the prefecture of Thua Thuan, 16° 30' N. lat., 107° 12' E. long., 10 miles from the mouth of the Hue river. It is built almost in the European style. Under the reign of King ChiaHung (1861—1829), it was strongly fortified by French officers, to whom, with a French bishop, that monarch was indebted for his throne; to which circumstance— in part, at least—may be referred the present occupation of Tonquin by the French. It is accessible only to vessels of the smallest class, owing to the shallowness of the small river on which it is situated. Pop. variously estimated at from 30,000 to 100,000.

HUÉ AND CRY, a phrase used in English law to describe the body of persons joining in the pursuit of a felon. Whoever arrests the person pursued is so far protected, that he requires no warrant to justify the arrest; and even if the party turn out to be no felon, no action can be brought if the arrest was made base or bad, but it is not only a defense to an action, but an offense subject to fine and imprisonment, to maliciously and wantonly raise the hue and cry against a person. It is the duty of all persons to join in a hue and cry, and if a person who has been robbed, either of life or liberty, is not known to be the hue and cry, he is liable to fine or imprisonment, or, according to some authors, to indictment; but these punishments are never inflicted.

HUÉLVA, a maritime and trading town in the south of Spain, capital of the modern province of the same name, which was formed out of a portion of the ancient kingdom of Seville (v. q.), is situated at the confluence of the Odiel and the Tinto, 63 miles west-south-west of Seville. The town is in constant communication with Portugal, Cadiz, and Seville; sends great quantities of fruit and fruit-matings to the latter places, and carries on an extensive tunny-fishery. The remains of the Roman aqueduct, which for many years has served as a quai, with a large group of lions, is now fast disappearing. Pop. 8423.

HUERTA, VICENTE GARCÍA DE LA, a Spanish poet and critic of the 18th c., was born in 1729 at Zafra, in Extremadura, but spent the greater part of his life in Seville and Cadiz, and was the principal librarian of the Royal Library, and where he died on 12th March 1797. He early distinguished himself by his poetical talent. His tragedy of Ruybal, founded upon the story of the love of King Alfonso VIII. for the fair Jewess Rachel, and its tragic catastrophe, was received with great enthusiasm when first produced in 1778, and is to this day esteemed as one of the very best of modern Spanish tragedies. H. was a most zealous but always a wise or skilful defender of the ancient Spanish national taste against the Gallicism which then prevailed. As a lyric and dramatic poet, he shews great command of language and versification. His poems were published in two volumes (Obras Poéticas, Madrid, 1778—1779). H. edited the Teatro Español (17 vols. Madrid, 1785—1786), a collection of the best works of the older Spanish dramatists.

HUESCA (the Oser of the Romans), a very old and picturesque town of Spain, in the modern province of the same name (see Aragon), is surrounded by old walls once surmounted by 99 towers, two of which only remain, and is situated in the midst of a plain covered with vineyards, on the right bank of the Isuela, 50 miles north-east of Zaragoza. Among its chief buildings are the cathedral, built in 1400, a beautiful Gothic edifice the university, founded in 1354 by Pedro IV.; and the picturesque college of San Pelayo. It was once famous as a seat of learning. Tanning and manufacture of linens are here carried on to some extent. Pop. 9874.

HUESCAR, a small town of Spain, in the province of Granada, is situated 75 miles north-east of the city of that name, and is said to contain a population of about 6000, who are chiefly employed in the manufacture of linen and woollen goods.

HUET, PETER DANIEL, was born at Casen, February 8, 1630. His father had been converted from Calvinism, but died while H. was still very young. The latter was educated in the Jesuit school of Casen, and was early distinguished by his extraordinary progress in almost every department of learning. He was a zealous pupil of Descartes and of Bochart—the latter of whom he accompanied on his visit to Stockholm in 1652, where he published and transcribed the MS. of Origen, which, subsequently, was the basis of his celebrated edition of that father. On his return to Casen, he gave himself up entirely to study; and as a preliminary to his translation of the text of Origen, he published, in 1669, the small known essay De Interpretatione; but it was only at the end of 15 years' study that he published his edition of Origen's Commentaria in Sac. Scripturam, 2 vols. fol. (Rouen, 1688), with a most learned introduction, entitled Origines, a work which has since been reprinted in the great Benedictine edition of that father. In 1670, H. received the degree of Doctor of Law; and soon after, he was summoned to Paris, to take part, with Bossuet, in the education of the dauphin. In 1673, he published his Demonstratio Evangelica. He had an active part, moreover, in the Delphic edition of the classics. In 1676, he entered into holy orders; and in 1678, was named abbot of the Cisterian abbey of Aunay, from which place is named his well-known work, Questiones Abbatiae de Concordia Rationis et Fidei (1690). About the same time, also, he published a work On the Site of the Terrestrial Paradise, another On the Voyage of Solomon, which to be followed later by his equally celebrated work in classical geography, History of the Commerce and Navigation of the Ancients. In 1685, H. was named Bishop of Soissons, a dignity, however, on which he never entered, being transferred to the see of Bayeux, which he took in 1692. He was as zealous in the discharge of his episcopal duties as he had been in his devotion to literature; but his health having given way, he obtained permission to resign his see in 1699, and retired to the abbey of Fontenay, near Caen; but, in 1701, he took up his residence in the Jesuit's house in Paris, and published, in 1717, his autobiographical memoirs—a model of pure Latinity as well as a most interesting record of the history of his time. H. died in 1721. His works were published in a collected form in 1712, and a volume of Huetiana appeared in the year following his death, 1722.

HUG, JOHN LEONHARD, was born at Constance, June 1, 1766, and educated at Freiburg, where in 1789 entered into priest's orders. In 1791, he was appointed professor of Oriental languages, and of the Old Testament, to which was added, in 1792, the professorship of the New Testament also. These united professorships H. continued to hold uninteruptedly for upwards of half a century, with the exception of some brief occasional visits to the great libraries of Munich, Vienna, Paris, Milan, Rome, and Naples. The most important fruit of
HUGO-HUGUENOTS.

His biblical researches was his Introduction to the New Testament, which appeared in 1806, in 2 vols., and which, besides several German editions, has been translated into most of the European languages. His great eminence as a biblical scholar led to his being called on to take part in the arrangement of the newly organised studies of most of the German universities—as at Breslau, in 1811; at Tubingen, in 1817; and again at Bonn, in 1818 and 1831. He died 11th March 1846. His works, which are indifferently in Latin and German, are chiefly in the department of biblical criticism and poetic. On the Apocalypse (1810), On the Conticle of Conticles (1813, and again 1818), On the Indissolubility of Marriage (1816), On the Alexandrian Version (1818), Re-examination of Strauss's Life of Jesus, 2 vols. (1835); but there are also some of them on subjects of classical criticism, especially an interesting work on the ancient mythology, published in 1812. See Maier's Gedächtnisrede auf Hugo, Freiburg, 1847.

Hugo, Victor Marie, Vicomte, one of the most distinguished French writers of the present day, was born at Besançon, in January 1802, at the age of 18, in 1826, at Paris, where his father was then commandant of the garrison. His mother was a native of La Vendée, and from her he imbibed romantic royalist sentiments, although his father, who had been devoted for the Napoleon, his youth was spent partly with his mother in Paris, partly in Italy and Spain, where his father held high appointments. He early acquired distinction by his poetic effusions; and before he was 30 years of age his published works were numerous, and his name famous. Odes and ballads, romances, drams, &c., flowed from his prolific pen. Shortly before the revolution of 1830, a literary revolution took place, at the head of which was Hugo. A band of young men, imaginative, ardent, and confident, sought to renovate French literature, by departing from classic rules and models, substituting a varied and very irregular verse for the monotonous Alexandrines of the old school, and making art precisely conform to nature, which they carried so far as even to bring into prominence things disagreeable, which nature itself is displeased with, and teaches us to keep out of sight. The new school, la joie France, as they called themselves, formed their theories and their opponents, the Classicists. The literary war which arose lasted for several years. His drama of Marion Delorme, produced on the stage after the accession of Louis Philippe, was received with great enthusiasm; and at the same time he added to his reputation as a poet by the publication of the elegies which bear the name of Feuilles d'Automne (Autumn Leaves). In 1832, the ministry of the day suspended the representation of one of his dramas, Le Roi d'Aumus; but his popularity still continued to increase, and in 1837, Louis Philippe made him an officer of the Legion of Honour, and in 1845 a peer of France. After the revolution of 1848, he was elected to represent the city of Paris, both in the Constituent and in the Legislative Assembly, in which he manifested democratic principles, and was one of those members of the extreme left who were banished from France for life by the Carrous Napoléon. He was arrested and confined in the island of Jersey. In 1852, he assailed the ruler of France in a remarkable political pamphlet, Napoléon le Petit (Napoleon the Little), which produced a great sensation; but the effect of its severity was weakened by its undignified virulence. In the following year appeared Les Châtiments, a series of poems written with great force, and in the same spirit as the brochure Napoléon le Petit. In 1858, he published his Contemplations, a work of more enduring merit; and the present year (1862) has just witnessed the conclusion of a large prose poem, entitled Les Misérables, in which the author, with a fine profusion of sentiment, keenness of analysis, and passionate dramatic force, handles, in the form of a story, some of the most important social questions.

His writings have great faults. They are often eccentric, and much in form and substance, and sometimes marred by an affected triviality of images and harshness of versification. Yet they have also great excellences, the command of language shown as a poet. Hugo, as a poet, has, perhaps, never been equalled in France.

HUGUENOTS (probably corrupted from the Ger. eidenoso, confederates), the name formerly given in France to the adherents of the Reformation. This movement commenced almost simultaneously in France and Germany. One of the most eminent names in the early history of French Protestantism is that of Faréol (q. v.), and one of the first supporters of its cause was Margaret of Valois, queen of Navarre, the mother of Francis I. Subhinc, in their days, of Calvinism of the nobles and middle classes embraced the reformed religion. Francis I., however, opposed it with great severity, and caused many to be burned as heretics. The alliance of England with the Huguenots was in support of the first impulse to the cause of the Reformation, but the aspect of things was again changed when the family of Guise obtained the ascendancy at court. Under Francis II., a chamber (chambre ardente) was established in each parliament for the punishment of Protestants; and executions, confiscations, and banishments were common in all parts of the kingdom. The Protestants took up arms against the government, choosing Louis I. Prince of Bourbon-Condé, for their leader. On February 1, 1560, in a meeting at Nantes, they resolved to petition the king for freedom of religion, and for the removal of the Guises; and in the event of his refusal, to seize the king's person, and proclaim Condé governor-general of the kingdom. But the court, being apprised of the conspiracy, fled from Blois to Amboise, and the Duke of Guise was appointed governor-general. Some bands of Huguenots, gaining on themselves, formed their own governments, and in their hands, were easily defeated and taken; 1200 died by the hand of the executioner. The Edict of Romorantin, in May 1560, took the prosecution of heretics out of the hands of the parliament, and put it in the hands of the Chamber of Notables in August, it was resolved that the whole matter of religion should rest until the next Assembly of the States. Whilst the Guises plotted the death of the Protestant leaders, Charles IX. ascended the throne, a prince not yet of age; and the queen-mother, Catharine de Meilllici (q. v.), having removed the Guises from the helm of the state, was compelled to seek the support of the Protestants against them and their partys. In July 1560, appeared an edict which freed the H. from the penalty of death. For the complete termination of strife, the court opened a religious conference at Poissy on the 3d of September. The chief disputants were the Carouss Napoléon, and Theodore Bœza (q. v.) on the other. The effect of the discussion was to unite and embolden the Protestants, with whom the machinations of the Guises forced Catharine into closer alliance. On January 17, 1562, appeared an edict, giving noblemen the right of the free exercise of their religion on their own estates. The Guises and their partisans became exasperated. On March 1, 1562, a company of Protestants met at a barn at Vassy for religious exercises, and
attacked, and many of them were massacred by the followers of the Duke of Guise. On this, Condé hastened to Orleans, and called his co-religionists again to his standard; whilst the Guises took possession of the persons of the king and his mother, and the rebels of the south and west. On September 11, 1562, the royal troops, after much bloodshed, took Romen, and on December 19 a battle was fought at Dreux, in which, after a hard struggle, the Protestants were defeated. The Duke of Guise himself was among the slain. The whole body of the rebels, which took up its quarter in the camp before that city, February 18, 1563. Hereupon the queen-mother hastened to conclude the peace of Amboise on March 19, by which the Protestants were allowed the free exercise of their religion, except in certain districts and towns. Condé, however, hated the new faith, and formed a close alliance with the Spaniards for the extirpation of heresy, rearmed the new liberties of the Protestants, and made attempts upon the liberty and the life of Condé and of the Adonis Coligny (q. v.). These leaders of the Protestant party adopted the resolution of taking possession of the king's person. The court fled to Paris, which Condé invested; but on March 26 of 1563, several places were secured by the Constable Montmorency (q. v.), in consequence of which Condé fell back into Lorraine, where he effected a junction with an auxiliary force of 10,000 men from Germany, under Prince John Casimir. After this, he again threatened Paris; upon which Catharine concluded peace at Longjumeau on 27th March 1568, re-establishing the terms of the treaty of Amboise. Nevertheless, she proceeded to persecute the Protestants, and on March 13, 1569, the Peace of Dreux was signed, by which peace was concluded or executed. The Protestants having, however, received assistance in troops from Germany, and in money and artillery from England, began the third religious war. But on March 13, 1569, the treaty of Dreux was broken, and the Protestants were again defeated by the Duke of Anjou at Montcontour, on 3d October. Fresh reinforcements from England, Switzerland, and Germany, enabled Coligny to take Nimes in 1569, and to relieve Rochelle, whilst Lamont obtained a victory over the royal troops at Luçon. Catharine and her son now sought for peace, to which the Protestants, weary of the hard contest, consented. The treaty, concluded at St Germain-en-Laye on August 8, 1570, gave to the Protestants an amnesty, the free exercise of their religion everywhere except in Paris, and the possession of a number of places of security.

Catharine, having failed to overthrow the Protestant cause in the open field, sought to accomplish her object by treachery, and by a public declaration of the Protestants on St Bartholomew's Day (q. v.) 1572. Although deprived of their leaders, and weakened by the slaughter of great numbers of their best soldiery, the Protestants, under the leadership of the Duke of Anjou, after having lost his army before Rochelle, took advantage of his election to the throne of Poland, and on June 24, 1573, concluded a peace, by which the Protestants obtained the free exercise of their religion in their places of security, Montauban, Nimes, and Rochelle, and a certain concession of liberty of conscience. A section of the Roman Catholic nobility, at whose head was the Duke of Alençon, the youngest son of Catharine, from purely political motives, united with the Protestants in opposition to the government of the queen-mother and the Guises. Catharine, therefore, incited her third son, Henry III., who had now succeeded to the throne, immediately to recommence hostilities against the Protestants. But, contrary to all expectation, the Protestant cause was in the highest degree prosperous during the year 1575. A peace was concluded at Beaulieu on 8th May, by which the Protestants were freed from the obligation of exercising their religion, and obtained a number of places of security. The king also paid their German auxiliaries. The Duke of Guise, thus frustrated in his political designs, originated a Catholic association, called the Holy League, at the head of which the king put himself in the Assembly of the States at Blois, on November 6, 1576, and then the sixth religious war began. Peace was, however, again concluded by the king himself at Bergerac, in September 1577, on the same conditions; and Catharine, to diminish the power of the Duke of Guise, entered into a private treaty with Henry of Navarre at Nerac, by which the royal power was more securely consolidated by the Protestants. The terms of peace being violated by the court, Henry I., Prince of Condé, son of Louis I., and, like his father, a leader of the Protestant party, commenced the seventh religious war (called the guerre des Trois Ans) in November 1577, with the occupation of Lafore, and Henry of Navarre, in April 1580, took Cahors. But Condé, having been driven out of Lafiére by Matignon, and Henry of Navarre vanquished at Mont-Crabel by Biron, in November 1577, the war was at an end.

There was now a comparatively long interval of repose till 1584, when, by the death of the Duke of Anjou (formerly of Alençon), Henry of Navarre became heir to the throne of France. Hereupon Henry, Duke of Guise, exerted himself for the removal of the League, entered into an alliance with Spain and the pope for the extirpation of heresy, declared the Cardinal of Bourbon heir to the throne, and began hostilities against the Protestants. This war is commonly known as the war of the three Henrys. The king soon made terms with him, and declared all the privileges of the Protestants to be forfeited. The Protestants, having obtained troops from the League, and money from England, signed an eighth religious war, which was prosecuted with various success, Henry of Navarre commanding the Protestant army. The Duke of Guise, in the midst of these troubles, grasped the whole power of the state. But his designs with regard to the throne having become very evident, the king caused him and his brother the cardinal to be assassinated at the Assembly of the States at Blois in September 1588. In less than a year, the king was himself assassinated by a monk named Jacques Clement, and Henry of Navarre succeeded to the throne, and signed the famous Edict of Nantes (see NANTES), on 13th April 1598, by which the rights of the Protestants were established and enlarged.

Under the reign of Henry IV., whose great minister, Sully, was himself a Protestant, the Protestants lived in tranquility. But when, during the minority of the king, the majority of the nobility turned to ardent Catholicism, the Edict of Nantes was revoked, and the Protestants enjoyed peace only in the provinces bordering upon the Spanish territories. In 1614 to 1615, the Edict of Nantes was renewed, and the marriage treaties with the Spanish court excited the apprehensions of the Protestants to such a degree that, in November 1615, they made common cause.
with the Frunt of Coméd, who had then set up the standard of rebellion. This they did contrary to the advice of the most sagacious of their own party. Although by the treaty of Loudun, 4th May 1616, they obtained a new confirmation of their freedom of worship, the court now only waited for an opportunity of breaking at least their political power. In June 1617, a royal edict commanded the entire suppression at once of the Protestant Church, and of all Protestant establishments, in the province of Lorraine; but the provincial court at Pau refused to register the edict, and the matter lay over till 1629, when, at the instigation of the Jesuits, and of his favourite De Layses, the king caused the edict, by force of arms. The Protestants throughout all France took alarm, and hostilities again broke out in May 1621. At the head of the Protestants were the two brothers, the Duke of Rohan and the Protestant who, in the fullness of their power, however, was freely maintained; almost all the Protestant towns fell into the hands of the king, force, stragazem, and bribery being equally employed. At last, after the capitulation of Montpellier, 21st October 1622, there fell, after all peace, by way of Levis, the Edict of Nantes was confirmed, but the right of prohibiting the assemblies of the Protestants was assumed on the part of the crown. The court, however, paid little attention to the stipulations of the treaty, and the campaign to maintain its privileges in Italy, the Protestants took the opportunity again to rise in arms. Soubise, with a fleet furnished by the town of Rochelle, oftener than once defeated the weak royal navy. Cardinal Richelieu (q. v.), who was now at the height of his power, had under the necessity of making offers of pacification, which were rejected. Hereupon the cardinal resolved upon the capture of Rochelle, the most important stronghold of the Protestants. This he accomplished after a heroic resistance by the inhabitants. The fall of Rochelle was speedily followed by that of Nantes, Montauban, Castres, and all the other Protestant strongholds. Now left the Protestants were entirely dependent on the will of the court, which, however, made no attempt to deprive them of their liberty of conscience. It was Louis XIV., when he became superstitious in his old age, who, at the instigation of Madame de Maintenon, and his confessor La Caille, commenced anew the persecution of the Protestants. He gradually deprived them of their equal civil rights, and endeavoured to put down the Protestant Church altogether. Bodies of troops, accompanied by monks, passed through the southern provinces, compelling the inhabitants to renounce their religion, demolishing the places of worship, and putting to death the preachers. Hundreds of thousands of Protestants fled to Switzerland, the Netherlands, England, and Germany. In vain was it attempted to restrain this self-expatriation by cords along the borders. Many Protestants also made an insincere profession of Roman Catholicism. These, on the slightest appearance of relapses, were put to death. On 24th October 1685, Louis at last revoked the Edict of Nantes. (See Ruhlbré, Éclaircissements Historiques sur les Causes de la Révocation de l'édit de Nantes, 2 vols. Paris, 1788.) Hereupon began a new flight, followed by a more fearful persecution of the Protestants. Their marriages were declared null; their children deprived of the right of inheritance, and forcibly shut up in convents; their preachers indiscriminately put to death. From the vicinity of Nantes, where they had always been very numerous, thousands betook themselves to the mountains of the Cevennes, and continued the exercise of their religion in secret. Amongst these and the mountainiers of the Cevennes, a remarkable fanatical enthusiasm displayed itself, and, under the name of Camisards, they maintained for a number of years a wonderfully successful opposition to the forces of the great monarchy. The War of the Cevennes (q. v.), or Camisard War, was not terminated till 1706, the suppression of the local rebellion being attended with circumstances of great cruelty. France had lost by this time more than a million of her most active, enterprising, and industrious inhabitants, notwithstanding all the persecutions, about two millions continued to adhere to the Protestant religion.

The partial reprobation which the Protestants enjoyed for a time was at length affected by a revival of their worship, especially in Provence and Dauphiné. In 1724, therefore, Louis XV., at the instigation of the Jesuits, issued a severe edict against them. The spirit of the age, however, now began to be opposed to persecution. An edict of 1759 declared marriages and baptisms by Protestant ministers to be null, and required the repetition of them by the Roman Catholic clergy. But when, upon this, many began again to flee from France, the Catholic Church, of itself, and the Catholics themselves so much excited, that the court recalled the edict. Montesquieu successfully advocated the cause of toleration; Voltaire did much to promote it by his exposure of the judgments and acts of the Inquisition. In 1777, a new edict, which indeed was not registered by the parliament till 1789, Louis XVI. declared the Protestant marriages and baptisms to be valid, and restored to the Protestants equal civil rights, except that they might not be admitted into the offices and dignities. Even in 1792, a proposal for the complete emancipation of the Protestants was rejected by the National Assembly, which, however, admitted Protestants as members without objection; and in 1790, it passed a decree for the restitution of all the properties of non-Catholics confiscated since the time of Louis XIV. The Code Napoleon gave the Protestants in France equal civil rights with Roman Catholics. The charter granted by the Bourbon acknowledged the freedom of Protestant worship, and the state pledged itself for the maintenance of the pastors; yet, under the government of the Restoration, the privileges of the Protestants were in many ways rescinded. After the revolution of July 1830, the Reformed Charter of France proclaimed universal freedom of conscience and of worship, which principle has been maintained in subsequent changes. Protestantism is now suffered to exist, but are subjected to many exceptional hardships, and have in various important instances been protected by the imperial authority from the arbitrary exercise of power attempted by illiberal local magistrates adverse to their religion. But the recognized Protestant Church—in which are included both Reformed and Lutherans, and of which the pastors receive small salaries from the state (see Frank)—is not permitted to hold synods or general assemblies; its affairs being managed by local consistory, somewhat analogous to kirk-sessions and presbyteries in Presbyterian churches, but of which by law those members of the congregation are members without office. But the Huguenots—HUILE DE CADE. A brownish, inflammable, oily liquid, obtained by the dry distillation of the wood of Juniperus oxycedrus. It has a strong odour of tar, and an acrid, caustic taste. It is almost entirely manufactured in France, and bore its name. It is employed externally in veterinary medicine, and has been used in the human subject both externally and internally, but chiefly externally in chronic skin-diseases. It is a good local
the exports being woollen and cotton manufactured goods, and the imports timber, corn, wool, iron, flax, hemp, tallow, pitch, bones, etc. In 1861, 6792 vessels, of 1,591,750 tons, entered and cleared the port. H. returns two members to the House of Commons. Pop. of municipal and parliamentary borough in 1861, 98,994.

HULSEAN LECTUREs, &c. The Rev. John Hulse, of Edworth, in the county of Chesterfield, who was born at Middleton, in 1708, and was educated at St John's College, Cambridge. Having no children, he bequeathed the bulk of his property to the university. His will, an extraordinary document, containing 400 pages folio, of closely written manuscript, with nine codicils appended, provides for the founding of two divinity scholarships in St John's College, the Hulsean Prize, the office of Christian Advocate, and that of Hulsean Lecturer or Christian Preacher. By a statute confirmed by the Queen in council in 1860, the office of Christian Advocate was changed into a professorship, called the Hulsean Professorship of Divinity. Bishop Elliot was the first professor under the new statute. The office of Hulsean Lecturer, or Preacher, is an annual one; and the duty of the lecturer is to preach not less than four, nor more than six sermons before the university in the course of the year.

HUMANITARIANS, the name assigned to the several classes of anti-Trinitarians, who regard Christ as a mere man, and refuse to ascribe to him any supernatural character, whether of origin or of nature. In this class are commonly enumerated the early Judaising sects of Ebion and Cerinthus; but this is by no means certain, at least as regards the former, who taught that the baptism in the Jordan the Demiurge descended upon Christ, and was united to him. The earliest recorded author of the purely Humanitarian theory is Theocles of Byzantium, the Grammar, who, having denied Christ in time of persecution, declared himself afterwards by declaring that in so doing ' he had denied not God, but man. A contemporary of Theocles, Artemon, taught in like manner that Christ was a mere man, and asserted that such had been the universal belief of Christians till the time of Zephyrinus, 202. These opinions must be carefully distinguished from the doctrines of the various sects of Arians, even the lowest schools of which have admitted the pre-existence of Christ, and his pre-eminence among the creatures of God.

The name Humanitarian is also sometimes applied to the disciples of St Simon, and in general to those who look to the perfections of humanity itself as their great moral and social dogma, and ignore altogether the dependence of man upon supernatural aid, believing in the all-sufficiency of his own innate powers.

HUMBER, the continuation and estuary of the river Ouse (q.v.).

HUMBLE-BEE (Bombus), a genus of social bees (see BEE), having a thick and very hairy body, the hairs often arranged in coloured bands; and also differing from the honey-bee in having the front edge of the hinder-legs terminated by two spines.
species are numerous, and are found in almost all parts of the world, from the equator to the utmost polar limits of vegetation, but they seem to abound most of all in temperate climates. About forty are natives of Britain, one of the largest of which, and of British hymenopterous insects, is the common H. (B. terrestris), the Bumble (boom-bee) of the Scotch; black, with a yellow ring before the wings, and another on the abdomen, the apex of the abdomen white. Another of the largest species is the Red-tailed Bee (B. lapidaria), and one of the most abundant is the yellow and orange Moos-bee (B. muscorum), the Fugge of the Scotch. Some of the tropical species are much larger than any found in Britain. The name H. is supposed to be a modification of Hummel or Hummer Bee, and to refer to the loud hum produced by the wings of these insects.

Humble-bees do not form communities so large as those of honey-bees; seldom more than two or three hundred occupying one nest, and in some species not more than fifty or sixty. The females are much less prolific than those of honey-bees. The community is dissolved on the approach of winter, the males and workers die, and only females remain in a torpid state—among moss, in rotten wood, in greenhouses, or some other situation where they may enjoy protection from frost, and concealment from enemies—to perpetuate the race by founding new communities in the ensuing spring. The nests of some species, as B. terrestris, are in holes in the ground, at the depth of a foot or more, floorcd with leaves, and lined with wax, and often entered by a winding passage. Others, as B. lapidaria, make their waxen nests among stones; while others still, as B. muscorum, make them among moss, which they mix and join with wax. The nests are the kind already noticed, and open cells or cells filled with honey, the frequent deposit of schoolboys, who know well how to open and plunder the humble-bee's nest. Many animals are also expert in this, as badgers, foxes, rats, &c., which, however, devour the wax as well as the honey.

HUMBOLDT, FRIEDRICH HEINRICH ALEXANDER, BARON VON, one of the greatest of naturalists, and who has contributed more than any man of modern times to the progress of several departments of physical science, was born at Berlin, 14th September 1769. His father, whom he lost when he was not quite ten years of age, was chamberlain to the king of Prussia. He studied at the universities of Frankfurt-on-the-Oder, Berlin, and Göttingen. His love of natural history was very strongly manifested at this period; he spent his residence at Göttingen (1789—1790), he made visits of scientific exploration to the Harz and the banks of the Rhine, the fruit of which was his first publication, 'On the Bees,' &c. In the spring and summer of 1790, he accompanied George Forster in a tour through Belgium, Holland, England, and France. In June 1791, he entered the Mining Academy at Freiberg, where he gave special attention to the art of mining, and spent eight months' residence here led to the subsequent publication of his Flora Subterranea Friderici et Aphorismi et Phylologorum Chimica Plantarum (Berlin, 1793). He was afterwards appointed to an additional department, and spent some years in this capacity, chiefly at the Friedrichberg, in Upper Franconia. His researches here resulted in a work 'On the Irritability of the Muscular and Nervous Fibres, with Conjectures regarding the Chemical Process of Life in the Animal and Vegetable World' (Ueber die Geruchte, &c., 2 vols. Berlin, 1797—1799).

The desire of visiting tropical countries, however, led him to resign his office, and devote himself entirely to the study of nature. He spent three months at Jena, where he was the intimate associate of Goethe and Schiller, and studied anatomy under Loder. Circumstances now led him to Paris, where he contracted a friendship with a distinguished young botanist, Aimé Bonpland (q. v.), afterwards his companion in many and various scenes. Some time after, he obtained permission from the Spanish government to visit all the Spanish colonies in America, and the Indian Ocean, with every additional favour which could promote his researches in the various departments of natural science. He sailed from Corunna, along with Bonpland, on 5th June 1799. They visited Teneriffe, ascended the Peak, and made many scientific observations. On 16th July, they arrived at Cumaná in South America, and in the course of five years explored a vast extent of territory in Venezuela, Granada, Ecuador, and Peru, whence they sailed for Mexico, which they crossed from west to east. On 7th March 1804, H. sailed from Vera Cruz for Havana, where he spent two months, completing the preparation of materials afterwards employed in his Essai Philosophique de l'Antique et du Precurseur, (Paris, 1824). From Havana he proceeded by sea to Philadelphia, and thence to Bordeaux, where he arrived after a course of travels unparalleled for variety and importance of scientific results. Here he contrived a friendship with the learned chemical constitution of the atmosphere. Having

Humble-Bees and Nest:

1. humble bee and nest; 2. orange-tailed bee; 3. mose bee.
HUMBOLDT.

visited Italy, and returned to Berlin, he accompanied Prince Wilhelm of Prussia in 1807 on a political mission to France, and obtained leave from the government of his own country to remain there; for the publication of his travels, for which the disturbed state of Germany at that time did not allow proper opportunity. He continued to reside in Paris till 1827. In 1807—1817, his great work, embarking 

on the new subject of geography, produced, folio and quarto, in each consisting of 29 volumes, and containing 1425 copper-plates. The wish of the king that he should reside in his native country, was finally carried into effect. He thus returned to Berlin, and there, in the winter of 1827—1828, he gave lectures on the Cosmos, or physical universe.

In 1829, H. again became a traveller, the Emperor Nicholas then sending out a well-appointed expedition to the southern hemisphere. He visited the Urals, the Altai Mountains, the Chinese Daonangai, and the Caspian Sea. In this expedition, H. was accompanied by his two friends, Ehrenberg and Gustavus Rose. Its principal results were the scientific examination of the beds which produce gold and platinum, the discovery of diamonds in an extra-

tropical region, the astronomical determination of positions, magnetic observations, and geological and botanical collections. The whole journey occupied nine months, and during its course, the description in Rose's 'Mineralogical and Geological Travels to the Ural, the Altai, and the Caspian Sea' (Mineralogisch-geographischer Reise, &c., 2 vols., Berlin, 1837—1842), and in H.'s Ann Centrale, Recueils sur les Chiffres, Molusca, and Geognostie comparée (3 vols., Paris, 1843). This expedition must be regarded as having also led to much increase of our knowledge of the earth's magnetism, through the adoption by the Emperor of Russia of H.'s proposal for the establishment of magnetic and meteorological stations from Petersburgh to Pekin; which was followed, on H.'s application to the Duke of Sussex, by the establishment of similar stations in the southern hemisphere.

The political changes of the year 1830 led to H.'s employment in political services. He had been long on friendly terms with the members of the House of Orleans, and therefore, after Louis Philippe ascended the French throne, he was chosen by the king of Prussia to carry to Paris his recognition of the new sovereign, and was afterwards, during the ensuing twelve years, frequently sent to Paris to reside for four or five months. He accompanied the king of Prussia in his tour to Scotland, and also to Italy and Spain.

During this time, he published his Examen Critique de la Geographie du Nouveau Continent (5 vols., Par. 1833—1838).

H. spent the latter years of his long life at Berlin, where he occupied a high position at the Prussian court. His last great work, Cosmos (4 vols. Stuttg. 1845—1858), has been unanimously recognised as one of the greatest scientific works ever published, exhibiting in most liad arrangement many of the principal facts of the physical sciences, and their relations to each other. It has been translated into all the languages in which a book of science is required. The germ of the work was the author's lectures on Natur und Welt (Ansichten der Natur, Stuttg. 1808). H. died May 6, 1859.

It is not easy to estimate the amount of H.'s contributions to science. The geography of Spanish America was most imperfectly known previous to his travels there, during which he astronomically determined more than 700 positions, and he bestowed much labour on the preparation of the maps in which his discoveries were exhibited. His barometric observations were likewise very numerous, as well as his observations on the points connected with meteorology. To him we are indebted for the most important generalisations concerning magnetism and also climate, some results of which are exhibited in the inderthmal and other lines which have begun to be drawn in our maps.

Among his botanical works, that on the geography of plants, De Distributione Geographica Plantarum &c. (Paris, 1817), was regarded as a sequel to his great work on the Cordilleren and Monumenta of the Sciences Indigene of the Amerique. He directed the attention of Europe to the monuments of a little known antiquity in America, and shewed for the first time the possibility of combining knowledge of plants and local position with accuracy. He published in 1823 an Essai Geographique sur le climat des Roche dans les deux Hemispheres (Paris); and in 1831, Fragmenta Geologica et Climatologia Sinonica (2 vols., Paris). In 1811, he published his work on political science, Nobilitas Politique sur le Royaume de la Nouvelle Espagne (2 vols., Paris), abounding in philosophical reflections as well as in statistical facts. He obtained distinction also by his labours in the determination of the magnitude of the magnetic equator, and by his observations on electrical cells, and on the respiration of fishes and young crocodiles. His labours have won him a high name in almost every department of science.

HUMBOLDT, KARL WILHELM, BARON von, the elder brother of the preceding, eminent as a statesman, and for his works in philology, aesthetics, and the Kautian philosophy, as well as on laws, to which he professedly devoted himself. After travelling in Germany, France, and Switzerland, he acquired the rank of counsellor of legation, but shewed little inclination for official employment, and in 1791 married Maria Antonia, daughter of a nobleman, on his wife's estate in Thuringia, and afterwards in Jena, associating most intimately with Schiller, and devoting himself to poetry and other literary pursuits. In 1819, he was made a professor of the valuable memorial of his friendship with Schiller is the correspondence between them (Briefwechsel zwischen Schiller und Wilhelm von Humboldt, Stuttg. und Tub. 1830), published by him after Schiller's death. From 1797 to 1798, H. resided partly in Paris and partly in Spain, and in 1801 became Prussian resident at Rome, where he remained for a number of years, in this capacity, and in that of minister-plenipotentiary, a most generous patron of young artists and men of science. From Rome he returned to his native country, to fill the high place of first Minister of Public Instruction, in which capacity he did much to promote education in Prussia. The Berlin university owed its existence to him. In 1810, he went to Vienna as minister-plenipotentiary, and when the Austrian nation took part in all the most important political affairs in which his country was concerned. After 1819 he resided chiefly at Tegel, where he laid out fine pleasure-grounds, and formed a noble collection of sculptures by the greatest masters. He died 8th April 1835.

His earliest literary works were collected by himself under the title of 'Aesthetic Essays' ('Esthetisches Werken, Brunswick, 1799). His 'Collection
HUMBOLDT—HUME.

Works appeared at Berlin (7 vols. 1841—1852). H. devoted himself with the greatest eagerness and success to the study of philosophy and produced a number of works in the Basque tongue, and the evidence which it affords concerning the aboriginal inhabitants of Spain—the languages of the East, and various questions connected with Oriental literature, and the languages of the South Sea Islands.

One of his most important works is that on the Kawi Language in the Island of Java' (Ueber die Kauensproche, &c., 3 vols., Berlin, 1836—1840), published after his death by Edward Buschmann; the introduction to which, On the Variety of Structure in Human Speech, and its influence on the intellectual progress of mankind, may be said to mark a new era in the science of philology, and has given occasion to many further researches and publications. Wilhelm von Humboldt's Briefe an eine Freundin, Leip. 1847 (Wilhelm von Humboldt's Letters to a Lady Friend), exhibit his character in a most pure and amiable light. This work has been translated into English.

HUMBOLDT, a river in the west part of Utah Territory, United States, America, formed by the union of two streams which rise on the west side of the Humboldt Mountains. It is a small and rapid stream, 350 miles in length, navigable even for canoes, strongly impregnated with alkaline matter, and after a westerly course, falls into a lake 48 miles in circumference, known as the Sink of Humboldt's River, which has no outlet. The banks are destitute of trees or shrubs, and the region through which it flows is one of the most barren in Utah. The valley of this river is the usual emigrant route from the Great Salt Lake to California.

HUME, DAVID, the philosopher and historian, was born at Edinburgh on the 26th of April (O.S.) 1711. His father was the laird or proprietor of the estate of Ninewells in Berwickshire, but David, being the younger son, had to make his own fortune with no other assistance than an education and the influence of his respectable family. He was educated at home and at the college of Edinburgh. His father designed law as his profession, and he submitted to the initial steps of the proper practical training, but it was not a pursuit to his liking. Deserting it, he experimented on a mercantile house in Bristol, but commerce was not congenial to him than jurisprudence, and he gave it a very short trial. He now devoted himself to contemplating books with no settled practical object before him. He has recorded his sufferings at this time from despondency and depression of spirits, caused, apparently, by the effects of monotonous study on the stomach. At 23 years of age, he went to France, and lived some time in La Flèche, where he describes himself as wandering about in solitude, and dreaming the dream of his philosophy. In 1739, he published the first and second book of his Treatise on Human Nature—the germ of his philosophy, and still perhaps the best exposition of it, since it has there a freshness and decision approaching to paradox, which he modified in his later works. Although the dawn of a new era in philosophy, this book was little noticed. It was a work of demolition. By separating the impressions or ideas created on the thinking mind by an external world from the absolute existence of that world itself, he showed that almost every current assumption of theism is taken for granted, and that demanded proof of its existence of a kind not yet afforded. It was thus that he set a whole army of philosophers at work, either to refute what he had said, or seriously to fill up the blanks which he discovered, and hence he originated both the Scottish and the German school of metaphysicians. In 1741 and 1742, he published two small volumes, called Essays Moral and Political; they were marked by learning and thought, and elegantly written, but are not among the more remarkable of his works. He felt keenly at this time the want of some fixed lucrative pursuit, and his longing for independence was the cause of a sad interruption to his studious and philosophical pursuits. He was induced to become the companion or guardian of an insane nobleman, and had to mix with the jealousies and mercenary objects of those who naturally gather round such a centre. In 1747, he proceeded to a still more congenial appointment, as secretary to General St. Clair, whom he accompanied in the expedition to the coast of France and the attack on Port L'orient, the depot of the French East India Company. In 1751, he published his Inquiry into the Principles of Morals, a work of great originality, and one of the clearest expositions of the leading principles of what is termed the utilitarian system. At the same time he issued to print his Dialogues Concerning Natural Religion, but his friends, alarmed by the sceptical spirit pervading them, prevailed on him to lay them aside, and they were not made public until after his death. In his 50th year, he had the happiness of being appointed to the Professorship of Moral Philosophy in Edinburgh, and at this period we find him unsuccessful in an attempt to obtain the chair of Logic in Glasgow. Next year, in 1752, appeared his Considered Discourses. Here he made an era in literature, for in this little work he announced those principles of political economy comprehending the doctrine of free-trade, which it fell to his friend Adam Smith more fully and comprehensively to develop. He was appointed, at this time keeper of the Advocates' Library, with a very small salary, which he devoted to a charitable purpose. It was here that, surrounded with books, he formed the design of writing the history of England. In 1753, he issued a reprint of the letters in the Spectator, containing the Reigns of James I. and Charles I., and presently completed this portion of the work in a second volume, bringing it down to the Revolution. He then went backwards through the history of English literature, and was the first to set the Roman period downwards in 1762. While so employed, he published Four Dissertations:—The Natural History of Religion; of the Passions; of Tragedy: of the Standard of Taste (1757). Two other dissertations, intended to accompany these, were cancelled by him after they were printed—they are On Suicide and The Immortality of the Soul, and were subsequently printed in his works. In 1763, he went to France as secretary to Lord Hertford's embassy; here he was in his element, and found fame at last. He became familiar with the brilliant wits and savants of the Parisian circle—with Turgot, D'Alembert, Helvetius, Holbach. Didot, Diderot, D'Aubigny, Condorcet, Pergaud, and above all, the able and extensive ten-year memoirs of the Journal des Sciences. The characters of the period, and the literary, philosophical, and political history of the time, are dissected, as well as with the no less distinguished female eminences, De Bouillers, Page de Bocage, Geoffrin, Du Deffand, and L'Esposasse. His sojourn in Paris was unfortunate in bringing him into intimacy with the restless, vain, and self-tormenting Rousseau, who, after experiencing much substantial kindness from H., got suspicious, and forced him into a memorable quarrel. After his return home, in 1766, he commenced the second volume of his History of England. He was elected a member of the society of Under-secretary of State for the Home Department. In his last years, H. says: 'I returned to Edinburgh in 1769 very
HUME—HUMMING-BIRD.

opulent (for I possessed a revenue of £1000 a year), healthy, and, though somewhat stricken in years, with the prospect of enjoying long my case, and of seeing the increase of my reputation. Early in 1774, he was attacked by the fever which for which he in vain sought a remedy in the Bath waters. He died at Edinburgh on the 25th of August 1776.

HUME, Joseph, politician, was born January 1777, at Montrose. His father was the master of a small coasting-vessel, who, dying while his family were young, left his widow and children in narrow circumstances. He was educated in the local schools of Montrose, and at the age of 13 was placed with an apothecary. He studied for the medical profession; was admitted in 1796 a member of the College of Surgeons, Edinburgh; and became assistant-surgeon in the marine service of the East India Company. He applied himself to the acquisition of the native languages, and during the Malhatta war, from 1802 to 1807, filled the office of Persian interjector to the army. He also discharged duties connected with the prize agencies and the commissariat, and arrived in England in 1808, usually found himself in active service of £30,000 on £40,000. He entered the House of Commons in 1812, as M.P. for the borough of Weymouth and Melcombe Regis. The future radical was then of Tory politics, and paid a sum of money for his seat, which he regained by a few months. He obtained, in 1818, a seat for the Aberdeen district of burghs, comprising his native town of Montrose. In 1830, he had gained such distinction as a radical reformer, that he was returned without opposition as one of the members for Middlesex, which he represented until 1837. In 1842, he was again chosen for his native burgh, Montrose, and remained until his death in the service of his fellow-townsmen. Although by no means a man of brilliant abilities, his indefatigable industry in every parliamentary duties, his plans of reform in every department of church and state, his hatred of sinecures and official abuses of every kind, and his advocacy of economy in the public service, made him one of the most useful and influential members of the legislature. He was probably often wrong-headed and mistaken, and as the leader of the Radical party in the House of Commons, usually found himself in active conflict with both Whig and Tory governments. Yet a tardy but sincere homage was paid to his integrity and public services by the late Sir Robert Peel and other political opponents. He died February 20, 1855, aged 78, leaving a name venerated by the masses of his fellow-countrymen for public honesty and personal disinterestedness.

HUMETTY, a term in Heraldry, applied to a cross or other ordinate which is cut off, and nowhere reaches the edge of the shield.

HUMIC ACID. See HUMIC.

HUMMELER, an implement or machine used for hummelling barley—that is, removing the awn from the grain after it has been threshed. A common kind of H. is a set of blunt knives fixed in a frame, with a handle, by means of which they are used in the manner of stamping. Another form consists of blunt knives set on a roller. These implements are worked by the hand. But hummellers of various construction are often attached to thrashing-machines, in all of which blunt knives are made to pass frequently through the grain.

HUMMING-BIRD (Trochilus), a Linnean genus of birds, now constituting a family, Trochilidae, of the order Insectivora, and tribe Lampornis. The species are numerous, more than 300 being known, whilst new ones are continually being discovered. They are found only in America and its islands, although represented, both in habits and in brilliance of plumage, by the Sun-birds (q. v.) of eastern tropical regions. Most of them are tropical, although a few species are summer visitants of the colder parts of America, very seldom, however, seen beyond lat. 57° N.; whilst some of those found only within the tropics inhabit elevated mountainous tracts, even to the confines of perpetual snow. The dazzling brilliancy of humming-birds, the extreme rapidity with which they dart through the air, their hovering above the flowers from which they obtain their food, with humming sound of wings, which move so quickly as to be indistinctly visible, or ‘like a mist,’ have attracted universal admiration since the first discovery of America. The diminutive size of almost all of them—some of them being the smallest of birds, and if striped of their feathers, not larger than a humble-bee—has still further contributed to render them objects of interest, whilst the plumage of the different species exhibits an almost endless variety of forms, as well as of colours, in crests, neck-tufts, leg-tufts, and many an extraordinary development of tail. Humming-birds have slender bills, which are also generally long, and in some extremely so, the form of the bill exhibiting a wonderful adaptation to the kind of flowers from which the bird obtains its food—straight in some, curved in others. Humming-birds do not, as was long supposed, feed on honey alone, but to a considerable extent, and some of them perhaps chiefly, on insects, not rejecting spiders, whilst they often snatch away the insects which have become entangled in spiders’ webs. The lower mandible fits into the upper, and the bill is thus adapted as a tube for sucking, in which, as well as in seizing small insects within the recesses of flowers, the tongue is also a very efficient organ. The tongue is very long, capable of being darted out to a considerable length; the bone of the tongue (hyoid bone) being much elongated, and its branches passing round the back of the skull to the forehead, where they meet in a point before the line of the eyes. The tongue itself consists of two filaments, joined together for the greater part of their length, and separated at the tip. The wings of Humming-Bird and Nest.
HUMORAL PATHOLOGY—HU-NAN.

Humming-birds are very long and powerful, the first quill-feather the longest, and the rest shorter in succession. Humming-birds construct their nests with nice art, generally of lichens and of fibrous substances, such as cotton. They do not lay more than two eggs. They are very bold in defence of their nests and young, and are said to strike fearlessly with their needle-like bills at the eyes of birds of prey, which they far surpass in agility and in the shortness of flight. They are perfectly tame and rendered familiar, and have been known to return again in spring, after a winter migration to a warmer climate, to the window from which they had been allowed to escape. Attempts to keep tamed humming-birds have generally failed, perhaps on account of their being supposed capable of feeding only on honey or syrup, whereas insect food seems necessary for them. Attempts made to bring them across the Atlantic have, in the great majority of cases, been unsuccessful.

We cannot propose to describe any of the species of H., nor to give the characters of the numerous genera into which the family has been divided. Formerly the colour is insufficient to convey a proper idea of their metallic and gem-like splendour, which in many cases varies with every change of position and of light.

The Ruby-throated H. (Archilochus colubris) is the one most commonly found in the Northern Atlantic states of North America. It ventures even into the regions of the Hudson's Bay Company.

The skins of humming-birds were employed for ornamental purposes by the more civilised Americal races and by the civilized Europeans, and were used by the Mexicans for making those pictures which so much attracted the admiration of their Spanish conquerors.

A full description, with many excellently coloured engravings, will be found in the Histoire Naturelle des Oiseaux-Mouches par R. P. Lesson, Paris, 1829.

HUMORAL PATHOLOGY. See Medicine.

Humus is a generic term applied to a group of closely allied substances, which collectively form the organic matter of the soil. These substances may be divided into three great classes: 1. Such as are soluble in water—crenic, crenic, and umic acids; 2. Such acids soluble in alkaline solutions, but not in pure water—humic and geic acids; 3. Such as are insoluble in all menstrua—humin and ulmin.

All of these are amorphous, ranging in colour from a brownish yellow to a blackish brown, and non-volatile; they are probably all composed of carbon, hydrogen, and oxygen, and they are all remarkable for their power of fixing ammonia. They are all products of the decomposition of vegetable matters in the soil, and are formed during their decay by a succession of changes, which may be easily traced by observing the course of events, when a piece of wood, or any other vegetable substance, is exposed for a length of time to air and moisture. It is then found gradually to disintegrate with the evolution of carbonic acid, acquiring first a brown, and finally a black colour. At one particular stage of the process, it is converted into one or more of two substances—humin and alumin, both insoluble in alkalies, and apparently identical with the insoluble humus of the soil; but when the decomposition is more advanced, the products become soluble in alkalies, and then contain humin, ulmin, and geic acids; and finally, by a still further progress, crenic and aporenic acids are formed, as the result of an oxidation occurring at certain periods of the decay.—Anderson's Agricultural Chemistry, 1860, p. 222.

The roots and other vegetable matters remaining in the soil gradually undergo the changes which have been described in the preceding extract and are thus converted into humus, which is found only in the surface soil, in which the varying cases with the activity and profusion of the vegetation.

Numerous analyses of the humus compounds have been made, but, as might be expected from the gradual passage of one substance into another, they have not been at all homogeneous. Mr. Mulder, who is perhaps the highest authority on this subject, geic acid is represented by $C_6H_9O_1;H$; humic acid, by $C_6H_9O_1;H$; ulmic acid, by $C_6H_9O_1;F$; crenic acid, by $3HOC_6H_9O_1;F$; aporenic acid, by $2HOC_6H_9O_1;F$. Crenic and aporenic acids (which derive their names from crene, the Greek word for a spring) not only occur in combination with ammonia, in the organic matter of the soil, but are likewise found in many mineral waters, and in the osyrr deposits that accumulate round the margins of chalky or springs.

All the above-named substances closely resemble in their composition the woody fibre or cellulose of trees, from which they are derived by a slow process of oxidation.

Chemists hold very different opinions regarding the physiological value of humus. The earlier chemists, and Mulder at the present day, regard it as a necessary and indispensable constituent of the organic constituents of plants; while Liebig and the great majority of the chemists of the present day regard the atmosphere (which consists of a mixture of nitrogen and oxygen gases, watery vapour, carbonic acid, and ammonia) as the cause and source of absorbing an abundant supply of all those substances. The latter is probably the more correct view; but although humus is not a direct source of the organic constituents of plants, and is not absorbed by their roots, as was formerly supposed, it is so indirectly in at least two modes—viz., by evolving during its decomposition a certain quantity of carbonic acid which can be absorbed, and by its power of absorbing and combining with ammonia, and with certain soluble inorganic constituents of plants. Its power of absorbing ammonia is readily shown by pouring some ammoporacnic acid black paste (which contains the humic compounds in great abundance); the jumngent smell at once disappears, which is an evidence that combination has taken place. It possesses a similar but less marked power in reference to potash, soda, chalk, and magnesia, and thus plays an important part in preventing these substances from being washed out of the soil. The physical properties of humus are also of great importance in relation to the fertility of the soil. Humus is one of the most highly hygrometrical substances known. While silicious sand absorbs only one-fourth of its weight of water, and again gives off, in the course of four hours, four-fifths of its water, humus absorbs nearly twice its weight of water, and retains nine-tenths of it after four hours' exposure. It thus confers on the soil the power of absorbing and retaining water, and thus diminishes its tenacity, and allows of its being more easily worked; and additionally, from its dark colour, it causes the more rapid absorption of heat from the sun's rays. Hence, although not contributing directly to the food of plants, it is in moderate quantity an indispensable constituent of a fertile soil. The best what-b апреля compounds contain 9 or 10 per cent. of humus compounds.

HU-NAN, a province in the lake district of China, on the south side of Tung-tung-hn, the largest lake in China. It is a fertile region, yielding two crops of rice annually, while its mountains yield malakicks,
HUNDRED—HUNGARY.

In the statistical returns of Baron Caxenning, published by the Austrian government in 1858, the soil under tillage (Transylvania included) is estimated at 22,651,438, and the pasture-land at 5,662,296 English acres. The difference arises chiefly from two circumstances: 1. By confining the river Tisa to its proper channel, new tracts of land came under cultivation. 2. By the parceling out of grounds upon the principle of modern farming, communal pastures became private property in many places, and were converted into soil under tillage.

Agriculture in H. is rapidly improving, as the great landed proprietors are enabled to introduce English machinery upon their estates, the great extent of level ground being admirably adapted for the use of such implements. A reliable calculation, the annual produce, in grains of every kind, amounts to 22,53,520 imperial bushels, leaving a yearly surplus for exportation of no less than 60,500,000 imperial bushels, of which a portion is exported for the wants of foreign markets.

The mineral wealth of H. may be said to be inexhaustible, but several branches of mining are as yet in their infancy. In 1858, the mineral produce was, in gold, 44,000 oz.; silver, 43,000 oz.; quick-silver, 194 01s.; lead, 27,200,000 lbs.; copper, 3,570,000 lbs.; cobalt, 3,780,000 lbs.; coal, 3,357,000,000 lbs. Rock-salt may be had to any amount in the mountains of Maramoros, as also in Transylvania. The quantity of wine is such that it might suffice for supplying the half of Europe. For the dessert-table, Tokay, Ménes, and Rıszt yield their delicious liquor, obtained from dry grapes. The red wines of Eger (Erlian), Buda (Öteu), Visonta, Karkovitz, Szepard, &c., may be said to equal the best produce of Burgundy; while the white wines of Magyaryt, Nezunyli, Somlyö, Pesth, Vilyany, Monostóli, &c., rank with the choicest of Rhénish wines. Tobacco, hemp, flax, rapeseed, timber of every variety, which would be extensively exported were the means of communication developed, and commercial intercourse guided by a more liberal policy, Fényes just put down the number of horses before 1848 at 360,000, and of oxen, 680,000; since that time the breeding has greatly improved. The oxen of H. excel equally in size and in the nourishing quality of the meat they yield. The number of sheep, according to Fényes, was 17,000,000, yielding an average quantity of wool yearly of 360,000,000 lbs., more than the half of which is above the average in quality. Among the 4,000,000 of swine, the Mangalica breed is much praised for its size, and for the hardness of the lard it yields. The rearing of bees and of the silk-worm is chiefly carried on in the Military Frontier. Industry and commerce are far from being in a state to bear a comparison with the wants of the people or with the natural richness of the soil; nevertheless, great progress is being made, this is due to the policy of ten years. Pesth, the capital of H., has been brought into direct railway communication not only with Vienna, but with Triest, Tomeshvar, Arad, Debreczin, and Kassa. A new line of railway is being carried through Transylvania. Fisheries are to be drawn into the net, so as to render it an outlet for the inexhaustible stores of the Banat, of Slavonia, and of Croatia, while the mountain districts of Upper H. are at work for a line extending to the very heart of Galicia.
HUNGARY.

Public banks, and other establishments of credit, are springing into life, and the speculators that weighed upon industry and commerce are being removed. A sound system of taxation, together with the revival of constitutional rights, would soon do the rest. Public education, especially in its lower branches, is rapidly extending. The colleges are of two kinds—gymnasia for classical education, and schools for industry and commerce. The higher branches of learning are carried on in academies and lyceums, as well as in the richly endowed Roman Catholic university of Pesth. Among the higher educational institutions of the Protestants, those of Debrecin and Sárospatak (for Calvinists), and of Eperjes, Pozsony, and Soprony (for Lutherans), occupy a very high rank. The Academy of Sciences, the Society of Naturalists, the Agricultural Society, the National Museum and Theatre, the Kisfaludy Society, together with more than 60 periodicals published in the Magyar tongue, speak well for the interest the Hungarian nation takes in progress and civilization. The following tables show the ratio of population, according to races and nationalities, throughout H., Croatia, and Slavonia:

There are, besides, a few thousands of Bulgarians, Montenegrins, French, &c.

At the head of the Roman Catholic Church in H. is the Prince Primate the Archbishop of Esztergom or Gran; there are two other archbishops, and seventeen bishops. The Greek Catholics have four episcopal sees in Hungary; a patriarchal archbishop and seven bishops. The two Protestant bodies are divided into districts, four for each; the heads of those districts bear the title of Superintendent.

It is generally admitted that the Hungarians—in their own language, Magyars—are of Scythian origin; their ancient seats being in the environs of the Caspian Sea. Part of the people emigrated in the direction of the Urals Mountains, and thence, being pressed by the warlike swarms of Paimacites, to the regions now known as Moldavia and the Ukraine. In 859, forty thousand families, counting more than 200,000 warriors among them, left their homes under the leadership of Almas, and after many a hard battle arrived at the northeastern frontiers of the land, which, under the name of Pannonia, contained several independent realms, such as Great Moravia, the Slavo-Bulgarian kingdom of Zahan, etc. The great taste of conquest being now at hand, old Almas resigned, and his son Arpád being unanimously elected as chief, the armed invasion began at once in several directions. At the end of 899, Arpád's sway extended from the Carpathians down to Servia, and from the eastern borders of Transylvania to the foot of the Styrian mountains. According to a covenant between Arpád and the other chiefs, the leadership was to remain with the descendants of the former as long as they should keep faithful to the nation. The foundations which were then laid for the political organisation of the realm, have been developed through lapse of time into that system of municipal independence which has outlived the storms of nearly a thousand years, and contains, even after the disastrous issue of 1849, the germ of future national greatness. The periods into which the history of H. is divided are: 1. Period of chiefs (899—1095); 2. Period of kings of the House of Arpád (1000—1301); 3. Period of kings from different (foreign) families (1301—1526); 4. Period of kings of the House of Hapsburg (1526 to the present day). The first king of H. was Stephen I., the great-grandson of Arpád; he was crowned in the year 1000 with a crown that had been sent to him by the pope, Sylvester II. It forms to-day the upper part of 'the sacred crown of Hungary.'

With St. Stephen, a new era began for H.; Christianity took the place of heathen superstitions; the savage incursions, by which the people of the east became a scourge to neighbouring nations, ceased entirely. The House of Arpád gradually declined, the grandest of whom undoubtedly was Stephen I., who, besides dividing the realm into ten bishoprics, more completely developed the administrative system. Among his successors, Béla II. (1101—1131) was a great favourite, as he had distinguished himself by his active prosecution of the rebellious attempt of a numerous party. Ladislaus I. is renowned for wise legislation and for great personal valor. Such was the renown of his deeds, that the Hungarian nobles, and afterwards the nation, by an unanimous act, elected him to be the king of Hungary. Janus Pannonius (1131—1141) was the next in order, and by his wisdom saved the state from the attacks of the Magyars and the Turks. His grandson, Stephen V., born in 1141, was crowned at ten years old; nevertheless, his reign is worthy of mention, for it was then that colonists from Flanders settled in Northern H., as also in Transylvania, in consequence of which, mining and several branches of industry made rapid progress. Andrew II. (1205—1235) is known in connection with the crusades; the Hungarian Magno Charta (Bulla Aurea), forced upon his predecessor, Henry II. (1205—1230), shewed great qualities in subduing the indomitable arrogance of the oligarchy, and in healing the wounds of his people after the terrible invasion of the Mongols in 1242. Andrew III. was the founder of the House of Arpád, in the Arpád line being thus without issue in 1301. During the mixed period, two kings, besides the governor Hunyady (q. v.), especially distinguished themselves. Lewis I., called the Great (1342—1381), was the second king from the House of Anjou, being by his great-grandmother connected with the Arpád dynasty. Lewis extended the sway of the Hungarian sceptre to limits formerly unknown; re-established at home the authority of law, trodden down by the mighty oligarchs under his predecessors; and promoted science, industry, and commerce. One of the remarkable episodes of his reign was the expedition to Italy to punish the assassins of his unfortunate brother, Andrew, spouse of the daughter of Hapsburg Henry V. (1355—1356), and (1457) is better known as Emperor of Germany. As a curious incident in the life of a sovereign, may be mentioned his imprisonment at Sighișoara during six months. Sigismund was released only after he had taken the oath to his Hungarian subjects, vowing fidelity to the constitution. Matthias I.—better known by the name of Mathias Hunyady or Mathias Corvinus (see Mathias)—may be said to have been not only the greatest king of H., but also the greatest sovereign of his age. By his valor, sage sty,
and love of learning, he raised his nation to the pinnacle of fame. From the death of Matthias to the day of Mohács, H. exhibits the fiercest strife of factions—a protracted agony, preceding the loss of national independence. Among the many calamities during the reign of Vladislaus II. of Bohemia (1490–1516), the Peasant War occupies a prominent place. Dáza and his bands, after having committed great havoc, were exterminated by the famous Jan Zapolya, of Transylvania, and the whole of the peasantries reduced to a state of servitude. Lewis II. was but ten years old at the death of his father, Vladislaus II. Another ten years of rapid disorganisation was required to make feeling with Catholic Mohács possible. See Mohács, BATTLE OF. The further history of H. is indissolubly connected with that of the Austrian empire, and may be read as to its principal features under the head AUSTRIA.

Hungary.—1. The Golden Bull of Andrew II., given in the year 1222, upon the return of the king from Palestine, contains 31 articles, of which article 2 is a kind of Habeas Corpus Act, but for nobles only. One clause of article 31, declaring that doing any illegal acts of the king not punishable by law, was cancelled by article 4 of the diet in 1657.

2. Treaty of Peace of Vienna, 1660. It was concluded on the 23d of June, between Mathias II. and Stephen Bocskay. Article 1 enacts the freedom of worship to Protestants, as far as is consistent with the established rights of the Roman Catholic Church.

3. Treaty of Peace of Linz, enacted during the diet of 1646–1647. Public worship is once more secured to Protestants, such freedom being for the first time extended also to the peasants. Protestants were to be admitted to public functions on an equal footing with Catholic Mohács.

4. The Pragmatic Sanction, contained in article 2 of the diet of 1722–1723. In case there should be no male issue in the dynasty of Hapsburg, the females and their descendants are to succeed to the Hungarian throne. The king must be a Roman Catholic, must take oath to the constitution, and sign the so-called diploma inaugurale, thus confirming the rights and privileges of the nation. Should there be no descendant, male or female, of the reigning house, the freedom of electing their king belongs to the nation.

Article 11 of 1741. Maria Theresa, abandoned by her allies, surrounded on all sides by fearful dangers, won the love of the Hungarian nation by acceding to their just and legitimate claims. The government of H. was confided to Hungarians only; in public affairs, the Prime, the Palatine, and the Ban were to be consulted. Hungarians were to be eligible for seats in the ministry. Article 17 of 1763–1769 renewed these enactments. Article 10 of 1790–1791 establishes the independence of the Hungarian kingdom with its annexed parts. Article 12 of the same year declares that the properties of nobles, changing, and increasing, in the kingdom of H. belongs to the sovereign legitimately crowned, together with the diet legally convened. Nothing can be done in H. by means of royal letters patent. Article 13 orders that the diet shall be convened at least once every three years.

Article 16 guarantees the nation the use and culture of the Magyar tongue.

Article 19 secures to the diet the right of voting taxes and of fixing the number of recruits.

Up to the year 1848, the nobles were free from contribution and military service; they occasionally gave subsidies; and in case of extreme necessity, rose in arms for the defence of the country. Article 8 of 1847–1848 enacts the great principle that all classes are to participate in the public burdens of the realm. Article 9 abolishes statute labour; the peasant could henceforward become owner of real property, and indemnity was given to their former masters. Article 10 of 1847–1848 establishes the principle of popular representation upon the basis of taxation.

Political Organisation of H.—The union between H. and the other Austrian empire is a personal one. The king exercises the constitutional power through the Aulic Chancery at Vienna. The highest dignitary of the realm is the Count Palatine (Comes Palatini), the highest judicial authority, either on civil or criminal cases. Buda, next to which is the Chief Justice (Judez Curia). At the head of the counties are lords-lieutenant and their deputies. The high court of justice is called Curia Regia. For the treatment of political affairs, the Congregations Generales, or general meetings of the counties, were of the highest importance. A very remarkable municipal independence was there displayed occasionally; those general assemblies had even the power of binding by instructions those who were to represent them at the diet.

Hungarian Language and Literature.—Notwithstanding the general sympathy that prevails for H., many are of opinion either that the Hungarians are but a half-civilised people, or that their language and literature are in some sense or another Germanic or Slavonic. The Magyar tongue is as much distinct from German or Slave as is the French or Italian. The language of the Hungarians is called Magyar, and forms, together with the Mogul, the group Ugr, belonging to the great Finnic family. As to its syntax, the language is nearest to the Turkish. Among its characteristics may be noted that the article H., the name occurring always in the second place, as, for instance, Hunyady János = John Hunyady. How rich in expressions, how abundant in classic beauties that language is, may be collected from the circumstance, that although it was excluded from public life during eight centuries (Latin being used in schools, legislation, and administration), H. possesses to-day a literature which, both in regard to its quantity and quality, will sustain a comparison with that of the most civilised among the western nations. Especially as regards poetry, the names of Kisfaludy, Vorómasy, Pestió, Arany, &c., are well worthy of being ranked with the best in other lands.

Those who are desirous of further information on this interesting subject, should consult Toldy’s admirable Handbook of Hungarian Literature, published both in Magyar and German.

HUNGARY-WATER, a very celebrated perfume, for the preparation of which various receipts have been given. The following is one of the best: Take of fresh rosemary in blossom, 4 pounds; fresh sage in blossom, 6 ounces; ginger in slices, 2 ounces; cut them in small pieces, mix, and add rectified spirit 12 pounds, and common water 2 pints. Let eleven pints distil by a gentle heat. A hermit is said to have given the original receipt to a queen of Hungary, and hence it was called the Queen of Hungary’s Water, which has been abbreviated into Hungarian Water. It is employed principally as a perfume for the toilet; but it is sometimes taken internally as a restorative and stimulant, and it may be used externally as a gently stimulating liniment.

HUNGER. See DIGESTION.

HUNINGUE, a small town of France, in the department of Haut-Rhin, is situated on the left

This place is remarkable as being the centre of the French system of pisciculture, or fish-breeding. A series of buildings and artificial ponds, covering a space of nearly seventy imperial acres, were erected on 1852—1854 for the breeding and acclimatizing of foreign fish. The total cost was £10,697. The expense of carrying on the plan from 1853 to 1862 amounted to £578, and the annual cost is now averaged at about £2000. This establishment has enabled the French government to restock many of the barren rivers of France with valuable fish. See Pisciculture.

HUNS (Lat. Hunni; Gr. Ουμνοι and Χοννοι), the name of a considerable nation of antiquity, which, from time to time, made incursions upon the Roman dominions, and which eventually, under Attila, the most renowned of its leaders, brought the empires of both the East and the West to the very verge of destruction.

The Huns of Asian origin, and, in all probability, of the Mongolian or Tartar stock; therefore akin to, and perhaps to be identified with, the Scyths and Turks. According to De Guignes, whose theory has been accepted by Gibbon, the Huns who invaded the Roman empire were lineally descended from the Hiong-nom, whose ancient seat was an extensive but barren tract of country immediately to the north of the great wall of China. About the year 200 B.C., these people overran the Chinese empire, defeated the Chinese armies in numerous engagements, and even drove the Emperor Kao-ti himself to an ignominious capitulation and treaty with the Tartars. According to the reign of Voight (141—87 B.C.), the power of the Huns was extremely great. On the other hand, the Roman emperors were the agents of a number of measures, all of which had the effect of weakening the power of the Huns, and facilitating their destruction. About the year 376, Attila, the greatest of the Huns, entered upon a warlike career, and succeeded in establishing his dominions in the tract of country between the Jisti, Huns, and Turcomans. He became the terror of the inhabitants of the countries which the Huns had invaded, and the most formidable enemy of the Romans.

HUNT, James Henry, poet and essayist, was born in London, 19th October 1754, educated at Christ's Hospital, and first attracted notice as a writer of theatrical and literary criticisms for the Examiner newspaper, which was started in 1765 by his elder brother John. At the age of twenty-four, he became joint editor and proprietor of the Examiner. He was a liberal in politics before liberalism had become fashionable; and for one of his articles, reflecting on the obscurity of the Prince Regent, he was fined five guineas. If the same thing had happened to him—"he was sentenced to pay a fine of £500, and to undergo two years' imprisonment. H. was happy enough in his confinement; he hid the prisoners, he joined in their games, and received visits from Byron, Shelley, and Keats. On his release, he published The Story of Round, which he had written in prison, and which gave him a place among the poets of the day. Fingal, appeared in 1818, and about the same time he started the Indicator, a serial suggested by the Spectator and Tatler. In 1828, he published Lord Byron and his Contemporaries, the record of a brief and not very pleasant companionship in Italy with his lordship, which gave great offence to Byron's friends. In the same year he started The Companion, a sequel to The Indicator, both of which were republished as one book in 1834. In 1833, he published a collected edition of his poetical works. In 1844, he started the London Journal, which he edited for two years. His principal works, besides those already mentioned, are—Captain Sword and Captain Pen (1830); Legend of Florence (1840); The Seer, a publication similar to The Indicator; The Palfrey (1842); Sir Ralph Fisher, a novel (1844); Imagination and Fancy (1844); Wit and Humour (1846); Stories of the Italian Poets, with Lives (1846); Men, Women, and Books (1847); A Jar of Honey from Moen.
**HUNT HUNTER.**

Hylde (1818); his *Autobiography* (1850); *The Religion of the Heart* (1853); and *The Old Court at Solar* (1855). In 1847 he received from the crown a pension of £200. He died at Highgate, August 28, 1869. A selection from his *Letters and Correspondence* was published by his son, Mr. Thornton Hunt, in 1862.

H.'s reputation rests upon his poems and essays. The *Story of Rimini* is, on the whole, perhaps, the finest narrative which has appeared since Dryden, and his *Polyphem* is delightful from its good spirit and bright sunny glimpses of landscape and character. As an essayist, he is always cheerful and fanciful, and he looks determinedly at the bright side of things. The sky may be gloomy, but if there is a bit of blue in it, he, with an admirable practical philosophy, constantly turns his eye to that. He delights to wreak the porches of the human dwelling with roses and honeysuckles. Among his poems are to be found several translations, which are the best things of the kind we possess. He transports the wine of Greece and Italy to England, and its colour and flavour are rather improved than otherwise by the voyage.

HUNT, William Holman, a celebrated English painter, was born at London in 1827, and exhibited his first picture, entitled 'Hark!' in 1846. During the next few years, his reputation steadily advanced; but while the young artist was winning fame, he was at the same time becoming more and more dissatisfied with the principles and practices that ruled his art, and along with Millais, Rossetti, and other young painters who shared his convictions, he commenced a new style of treat- ment, known as the *Pre-Raphaelite*. This term was first applied to H. and his friends, who employed them to indicate their predilection for the painters who lived before Raphael, such as Giotto and Fra Angelico, but did not at all imply that they meant to take the productions of these masters as technical models. It was because of their truthfulness and earnest simplicity that they professed to admire the antique fathers of Italian art. The first of H.'s works that showed the new influence was his *Converted British Family sheltering a Christian Missionary from the Persecution of the Druids* (1850). Since then he has produced, among others, 'Valentine rescuing Sylvia from Proteus,' 'The Hurling Shepherd,' 'Our English Countryman,' 'The Thoughtful Conscience of the World,' 'The Scape Goat,' and 'Christ Disputing with the Doctors in the Temple.' Of these, the last three are unquestionably H.'s greatest; and multitude of people, who neither understand, nor care to understand the recita *quarta* of Pre-Raphaelits, have been profoundly moved by the tenderness, purity, strength, and truth of religious sentiment by which they are inspired.

HUNT, William, an eminent English painter in water-colours, was born in London in 1790. He ranks very high in his profession, not only with an authority than Mr. Ruskin pronouncing him to be among the greatest colourists of the English school. His subjects are very simple—'Peaches and Grapes,' 'The Shepherd's Cottage,' 'Basket of Flowers,' 'Trampers at Home,' 'A Farmhouse Beauty,' 'Fast Asleep,' &c., but they are conceived in a finely poetical spirit, and present the perfection of finish.

HUNTER, John, the greatest name in the *country* character, who has shown that the whole annals of medicine can furnish, was born at Long Calderwood, in Lanarkshire, in 1728, and was the youngest of ten children. One of his brothers, William, claims a separate注意。他的一个姐妹，Dorotha，与Dr James Baillie，教授在格拉斯哥大学，且是Matthew Baillie (q.v.) 的母亲。The fact that his father died when H. was only ten years of age, and the probability that he was over-indulged by his mother, explain how, at the age of twenty, he could simply read and write, and was ignorant of every language besides his own. The fame of his brother William's success as a poet and a lecturer, made H. decide on entering into the same profession, and he accordingly applied for and obtained the situation of assistant in the dissecting-room. His progress in anatomy and surgery was so rapid, that in the second session he was able to undertake the directing of the pupils in their dissections. He studied surgery under Cheselden (the celebrated lithotomist), at Chelsea Hospital, during the summer months of 1749 and 1750; and subsequently under Pott.

In 1753, H. entered as a gentleman commoner at St Mary's Hall, Oxford; but finally deciding on confining himself to the practice of surgery, he entered St George's Hospital, as surgeon, April 1, 1754, and two years afterwards served the office of house-surgeon. In the course of this year (1754), H. became a partner with his brother in the anatomical school. After ten years' hard work in the dissecting-room, his health began to give way, and in 1759 he was strongly advised to seek a more southerly climate. With this view he applied for an appointment in the army, was immediately made staff-surgeon, and went out to Belgium, and afterwards to the Peninsula; but in 1763, peace having been proclaimed, he returned home, permanently settled in London, and with nothing but his half-pay and his own talents to support himself started as a pure surgeon. For a while he had not a great practice, and consequently devoted much time and money to comparative anatomy. He was in the habit of purchasing the bodies of animals that died in the Tower, and in travelling amongst disease, and in travelling amongst

Mrs Hunter had a taste for music and the author of several popular songs. *My Mother bade me bind my Hair* is one of hers, and was written to an air of Pleydell's.
the tumour, and between it and the heart, thus introducing into surgery an improvement which has been more fruitful in important results than any since Ambrose Paré's application of ligatures to divided arteries. In 1756, H. was appointed deputy-surgeon-general to the army; in 1787, he received the Copley medal from the Royal Society. He was now universally acknowledged, by all the younger surgeons, as the head of his profession; but most of his contemporaries looked upon him as little better than an innovator and an enthusiast. He died 16th October 1793, and was buried in the church of St. Martin's-in-the-Fields, from whence his remains were removed, in 1860, to Westminster Abbey, where a suitable tablet to his memory has been erected by the Council of the Royal College of Surgeons.

Some idea may be formed of H.'s extreme diligence, by the fact that his museum contained at the time of his death 10,563 specimens and preparations of illustrative human and comparative anatomy, physiology, pathology, and natural history. He died in comparative poverty, and his collection was purchased in 1799, 4 years after his death, by government for £15,000, and was presented to the Royal College of Surgeons, by whom it has been much enlarged.

In addition to numerous papers contributed to the Transactions of the Royal and other learned societies, he published the following independent works: A Treatise on the Natural History of the Human Teeth (part i. 1771; part ii. 1775); A Treatise on the Venereal Disease (1786); Observations on Certain Parts of the Animal Economy (1786); and A Treatise on the Examination, and Quasishot Wounds (published in 1794). Mr Palmer, with the literary assistance of several eminent surgical friends, published an excellent edition of The Works of John Hunter, F.R.S., with Notes, in 4 volumes, in 1835. To this is prefixed The Life of John Hunter, F.R.S., by Drewry Otley, from which most of the materials of this sketch have been taken.

HUNTER, William, M.D., the elder brother of John Hunter, was born at Long Calderwood, in the parish of Kilbarchan, Lanarkshire, in 1718, and died in London in 1783. After studying for five sessions in the university of Glasgow, with a view to entering the church, he determined to devote himself to the profession of physic, and passed the winter session 1740—1741 in Edinburgh, and in the summer of 1741 arrived in London, where he resided with Dr James Douglas, the well-known anatomist and obstetric physician, for the double purpose of assisting in dissections, and superintending the education of his son. H. was then entered as a surgeon's pupil of St George's Hospital, and as a dissecting pupil of Dr Frank Nicholls, who was then teaching anatomy with great success. To teach anatomy was now the object of his ambition, and in 1746 an opportunity of doing so occurred. A society of naval surgeons had for several years engaged Mr Sharpe to deliver a course of lectures on the operations of surgery, and on his resignation, H. received the appointment with much satisfaction, that the society requested him to extend his plan to anatomy. In 1747, H. was admitted a member of the Corporation of Surgeons. In the early part of his career, he practised both surgery and midwifery, but he gradually confined himself to the latter line of practice. He was appointed one of the surgeons-accoucheur to the Middlesex Hospital in 1748, and to the British Lying-in Hospital in 1749.

In 1762, H. was consulted by Queen Charlotte, and two years afterwards was appointed physician-extraordinary to her majesty. In 1767, H. was elected a Fellow of the Royal Society, and in the following year was appointed professor of anatomy to the Royal Academy. In 1770, he removed to Great Windmill Street, where he had built a house, in connection with which there was a roomy amphitheatre for lectures, a dissecting-room, and a magnificent room which was to form his museum, which consisted of anatomical preparations executed by himself and his pupils, purchases from other museums, also minerals, shells, and other objects of natural history, and was studded with a very rare cabinet of ancient medals and coins.

The estrangement which took place between H. and his brother continued till the former was on his death-bed, when his brother requested that he might be admitted to see him. This was acceded to, and he continued to visit him daily, and to afford him professional assistance, until his death. Together with the bulk of his fortune, H. left his museum to Dr Baillie for a period of thirty years, after which it was to be handed over to the university of Glasgow, to which institution he bequeathed £8000 for its maintenance and increase.

H. excelled as a lecturer in clearness of arrangement and force of language. H. recorded in a letter of augmentation: 'He was, perhaps, the best teacher of anatomy that ever lived.' He published several important contributions to medicine, of which the most important is his Anatomical Description of the Human Gravid Uterus and its Contents, which did not appear in its perfect form till after his death.

HUNTER, the name of a river in New South Wales, which enters the Pacific 75 miles north of Sydney.

HUNTING HORN, or BUGLE HORN, is a frequent bearing in Heraldry. When adorned with rings, it is said to be garnished. If the mouth and strings of the instrument are of a different tinture from the horn, this must be named blazon.

HUNTINGDON, a market-town and parliamentary and municipal borough of England, capital of the county of the same name, is situated on the left bank of the Ouse, 20 miles west-north-west of Cambridge, and 60 miles north of London. Among the most interesting buildings is the house of Oliver Cromwell and Cromwell Hall, which contains numerous schools, among which is the grammar-school, with an endowment of £100 a year, and two exhibitions for Cambridge University. Manufactures of bricks and tiles, and a trade in wool and corn, are here carried on. Pop. in 1861, of municipal borough, 3816; of parliamentary borough, 6254.

HUNTINGDON, Selina, Countess of, celebrated in the religious history of the 18th c., was the second of three daughters and co-heiresses of Washington Shirley, second Earl Ferrars, and was born August 24, 1726. She married, in 1728, Theophilus, 9th Earl of Huntingdon, a very pious nobleman, and became a widow in October 1748. Adopting the principles of the Calvinistic Methodists, she arranged which sect was the famous George Whitefield, she made that eminent preacher one of her chaplains, and assumed a leadership among his followers, who came to be known as 'The Countess of Huntingdon's Connection.' On Whitefield's death in 1770, she was appointed by his will sole proprietor of all his possessions in the province of Georgia, on which she immediately set about organising a mission to North America. Her labours at home increased with her years. For the
education of ministers, she established and maintained a college at Trevecca, in Wales; removed, in 1792, to Cheshunt, Herts; and built, or became responsible for, numerous charities in the western counties of the country, the principal one being at Bath. She likewise expended large sums in the support of young men trained to itinerant preaching, as well as in private charity. But with all her excellences, she was not Hongruda pleasant in the presence of a male pope, and had quite a passion for carrying her point. She died June 17, 1791. By her will, dated January 11, 1790, she created a trust, bequeathing her chapels to four persons, of whom Lady Anne Erskine, a daughter of the Earl of Buchan, was one, for their care and management after her death, when the number amounted to 64. Most of them have become, in doctrine and practice, almost identical with the Congregational or Independent body.

In 1851, there were 169 chapels belonging to this connection in England and Wales.

HUNTINGDONSHIRE—HURDLES.

HUNTINGDONSHIRE, a small inland county of England, is bounded on the E. by Cambridgeshire, on the S. by Bedfordshire, and on the W. and N. by the county of Northampton. Area, 250,475 acres, of which 35,500 are arable, 51,800 grass, 176,675 waste, and 4,600 water. The whole of the county is divided into 34 hundreds which are divided into 154 parishes. The county returns two members to the imperial parliament. The county of H. was traversed by two Roman roads, and Roman remains, as coins, pottery, &c., have been found.

HUNTSVILLE, a small borough of barony and market-town of Scotland, in the north-west of Aberdeen-shire, situated at the junction of the Bogie and the Deveron, 20 miles south-south-west of Banff. In the vicinity is the ruin of Huntly Castle. Pop. (1861) 3449.

HUNYADY, János (Eng. John), governor of Hungary, one of the greatest captains of his age, was born towards the close of the 14th century. His origin is wrapped in mystery, the most accredited legend being that he was a son of the Emperor Sigismund by a Wallachian lady. His and his descendants had in their escutcheon a raven—corvus—hence the designation of Corvinus. We find H. as Ban of a province south of the Danube, distinguishing himself against the Turks who at that time were the terror of the whole of Christendom. During the period 1437—1456, H. was the shield of Hungary, not only against external foes, but also against the lawless attempts of the nobles. Such was the renown of H.'s arms that, after the campaign of 1444, the Turks were glad to obtain an armistice of ten years. The magnifying Vladislaus I. allowed himself to be induced by the papal legate, Julius Cesarini, to break the peace he had sworn to keep. H. was defeated in the bloody battle of Varna, 1444; the king perished in the fight, as also the cardinal-legate; H. was captured during his flight by the voivod of Wallachia; but upon a declaration that the nobility of Hungary would rise to deliver the noble prisoner, was safely escorted to the frontier, and there set free. During the minority of Ladislaus V. (son of Vladislaus I.), H. was elected king by the nation, and by the battle of Rigómagó (1447), one of the bloodiest ever fought, was lost through the treason of the voivod of Wallachia; H. had once more to go through a short captivity. But the most splendid achievement of his deeds was the storming of Belgrade, where the monk, John Capistran, carrying the holy cross, raised the enthusiasm of the Christian warriors to such a height, that a most complete victory brought that fortress again into the possession of the Hungarians. Shortly afterwards disunity broke out in the camp, and H., the great Christian hero, after a short illness, fell a victim to the disease. Capistran, seventy years old, followed his friend into the grave two months later. H. left two sons, Ladislaus and Mathias (q. v.); the former of whom was treacherously imprisoned, and beheaded at Buda, by the very prince whom his father had so faithfully served, Ladislaus V.; the latter was given in charge to George Polichar (q. v.) of Bohemia.

HUPE: H., one of the central provinces of China, reputed the most fertile. The great river Yangtze flows through the south of the province, where it receives tributaries with various lakes on either side, nearly doubling its volume of water. Area, 70,450; population, 27,573,098. Wuchang is its capital.

HU'RA, a genus of plants of the natural order Euphorbiaceae. H. crepitans, a native of the West Indies and tropical America, is a tree abundantly in a very aerial milky juice; with scored, heart-shaped, acuminate leaves. The fruit is a woody capsule, of the size of a pretty large apple, very much flattened, formed of 12—15 cocci, each containing a large seed, surrounding a common axis, which separate with great elastic force. Before the use of blotting-paper became general, the capsule was generally used in the West Indies as a sand-box—whence the tree is called SAND-BOX TREE—for powdering letters with fine sand; but it was found necessary to land it with a loop of iron, as even after being used for years, it would sometimes burst with a report like that of a pistol. The seeds are a violent druggastic purge.

HURD, Richard, D.D., an eminent English prelate, was born at Congreve, in Staffordshire, on January 13, 1699, and studied at Cambridge University, of which he became a fellow in 1742. In 1749, appeared his first notable production, Commentary on Hosea's Are Poetical. In 1750, through Warburton's recommendation, he was appointed one of the Whitehall preachers, and ultimately rose to be Bishop of Lichfield and Coventry. He died May 28, 1808. His principal works are—Dialogues on Sincerity, Retirement, The Golden Age of Elizabeth and the Constitution of the English Government (1759); Letters on Chivalry and Romance (1762); and An Introduction to the Study of the Prophecies Concerning the Christian Church (1772). Ballam says of H., that he 'has perhaps the merit of being the first who, in this country, aimed at philosophical criticism.'—Literary History of Europe, 4th edit. Lond. 1854, iii. 475.

HUR'DLES, in military affairs, consist of straight flat rectangles of strong wicker-work, about 6 feet long and 2 feet high. They are useful in many ways, both in military and civil life, either as fencing, as barriers, or in fortification, in the construction of hurdle-batteries. These last were the invention of Sir William Congreve, who devised them with the specidest means of throwing hurdle-work: three hurdles are fastened at their ends in
HURDWAR—HUSBAND AND WIFE.

The form of a triangle, and the central space is filled in a short time with earth. These triangles can be constructed to any ground-plan, and with their aid, a body of soldiers can entrench themselves in a few minutes. The hurdle is composed of wattles interwoven (as shown in the diagram) round stakes or pickets, the latter during the manufacture being fixed upright and firmly in the ground.

HURDWAR, perhaps the most famous spot on the Ganges, stands on the right or west bank of the river at the point where it emerges from the sub-Himalaya into the plains of Hindustan. From its position on the sacred stream, it attracts immense numbers of pilgrims for the purposes of ablution. The orthodox season comprises the end of March and the beginning of April—a great fair at the same time, creating commerce of all kinds. In ordinary years, the attendance amounts to 200,000 or 300,000; but on the occasion of every twelfth year, the latest having occurred in 1856, the visitors, from the commencement to the close of the festival, are estimated to exceed 2,000,000. The place is 1024 feet above the sea, in lat. 29° 57' N., and long. 78° 14' E.

HURDY-GURDY, a very old musical instrument of the stringed kind, which, under the name of L dans, or Baudenkyer, spread from its native country, Germany, over a great part of Europe. The Hurdy-gurdy consists of a flat, oval-shaped sounding-board, over which the strings are stretched, with a back or bottom of the same size and shape. These are bound together by tolerably deep sides, or ribs. On one side are ten to twelve finger-keys, for shortening the sounding lengths of the strings when required. There are four strings, of gut, which are put into a state of vibration by being rubbed by the edge of a small wooden wheel charged with rosin, and turned by a handle. Two of the strings are tuned in unison as a key-note, or one of them a fifth above; they are placed out of reach of the keys, and form a sort of drum-base. The other two strings are acted on by the keys, and produce a diatonic scale from ten to twelve notes. The Hurdy-gurdy is only suited to simple music, and was used for such as had many repetitions. Its simplicity and cheapness rendered it, at one time, a favorite instrument among the peasantry of Europe. The instrument is now mostly to be seen in the hands of Savoyard boys, who play it on the streets.

HURON, one of the five great lakes of the St Lawrence, has Superior and Michigan above and Erie and Ontario below it. It separates Upper Canada from the state of Michigan, and extends in N. lat. from 43° to 46° 29', and in W. long. from 79° to 85°, and has been estimated to contain about 20,000 square miles. Its surface is 884 feet above the level of the sea; its depth about 1000 feet. Its waters are remarkable for their clearness and purity, whence the lake received from the French traders the name of Muer Ducus, or Fresh Sea. The total body of water is said to contain 3000 islands, one of them, the Great Manitoulin, or Sacred Island, running parallel to almost the whole of the northern coast, which is one continuous mass of comparatively barren rocks.

HURRAH! a shout of encouragement and applause, peculiar to the English. It serves also as a war-cry. As an engagement at sea commences, the crews of the English vessels send up deafening hurrahs; in a charge on shore, English soldiers hurry as they rush upon the enemy. There is a certain drubbing excitement in this simple sound, and the comatants work themselves, as they shout, into a frenzied forgetfulness of danger.

HURRICANE. See STORMS AND WINTERS.

HURST, a charge in Heraldry representing a small group of trees, generally borne upon a mount in base.

HUSBAND AND WIFE are the correct legal as well as popular terms to denote two persons married to each other. The modes of contracting marriage, with the accompanying ceremonies, and the impediments to marriage, will be more properly described under the head of Marriage (q. v.), and the mode of dissolving the marriage has been already partly described under Divorce (q. v.). The effects of marriage on the parties, and upon their property, will here be described, for which purpose the relation of husband and wife will be assumed to have been duly constituted. And as the effect is not the same in all parts of the United Kingdom, the laws of England and Ireland, which agree in this respect, will first be stated, and afterwards those of Scotland separately.

Marriage in England and Ireland may be viewed under two heads—first, as regards the persons and the personal rights of the married persons; and secondly, as regards their property. So far as regards the person of the husband, he remains in precisely the same position as before marriage. He can sue and be sued, enter into contracts, and bind himself as fully after as before marriage, and he can even make a will, and bequeath all his property to strangers, regardless of the wife. As regards the person and personal rights of the wife, however, there is a material difference. Her person is said to be merged in that of her husband, and for many purposes she is treated as one person, in the eyes of the law. The meaning of that is, that the wife is under many disabilities. She cannot enter into contracts in her own name, and for most of the purposes of business she cannot be endowed with as apart from her husband. Even the personal property she had before marriage, unless settled upon by her some settlement made before the marriage, becomes her husband’s absolutely, and he can dispose of it at will. The power which the wife can do in the way of entering into contracts after marriage, is to order goods and necessaries for the use of herself and family and for household use; but this she does not in her own right, but merely as the agent of the husband, who is presumed by the law to give her an implied authority to that effect, and therefore the wife, when ordering goods, does not in any way bind herself, but merely her husband. As, however, this power is often abused by extravagant wives, the law qualifies the power in this way, that the goods and necessities so ordered must be reasonable, and suited to the rank and position in life of the husband. If goods are therefore ordered which are extravagant, the husband canrepudiate the contract, and return them, but he cannot keep the goods and refuse payment; if, for example, he has seen his wife wearing an expensive dress which he knows he did not himself order or pay for, if he do not at once repudiate the transaction, and return the goods, he will be held to have consented and approved of the purchase, and he cannot afterwards repudiate liability for the price. This position of husband and wife is taken advantage of in the lower walks of life by means of the tally system.
HUSBAND AND WIFE.

which is the cause of much demoralisation. The tallyman calls upon the wife in the husband's absence, and offers her goods, which are generally in the end charged for at an exorbitant rate; but as he consents to take payment by instalments, and as the wife is advised to pay them secretly, the result is that the husband's money is often squandered. These transactions being a fraud on the husband, if he acts under the compulsion or of the first moment he becomes aware of them, the husband repudiates them; and a county court or any other court, would give him every assistance in getting rid of any liability so incurred, if he should afterwards be sued; but it generally happens that the matter has advanced too far before it is discovered; or he has done something which is construed into an adoption of the contract; or, what is frequently the case, he ignorantly supposes that he has no remedy.

The husband, being entire master of his own actions, has the power to decide where to live, and the duty of the wife is to live with him in the same house. If she refuses to do so, and lives apart without just cause, he is not bound to support her even with necessaries. If, however, she separates from him for just cause, the case is otherwise. Though the husband is bound to maintain his wife, there is, curiously enough, no direct equitable remedy for enforcing this duty. There are circumstantial means only. The wife, for example, cannot sue the husband herself, but she has an implied authority to order necessaries, and the tradesman so supplying these can sue the husband for the price. Hence it is that when a tradesman supplies a wife, who is living apart, with necessaries, before he can be sure of recovering the price from the husband, he must sue the other party; and the present case, of course, is an exception to the rule;

there is no other case where the wife can act for the husband. In such cases, the husband is again charged.

And the wife may therefore be able to sue the husband in criminal cases, and suits relating to debts, contracts, and wrongs which are not crimes, and in all inquiries of a civil nature. So when the husband is himself a party in a civil action, his wife may be compelled by the prosecutor and the other party to give evidence against him. Moreover, if the husband is himself a party in a criminal proceeding instituted against either husband or wife, the other spouse is neither competent nor can be compelled to be a witness; but the wife can be called in criminal proceedings made by or to the other spouse during the marriage. As regards all proceedings instituted against either husband or wife, the other spouse is neither competent nor can be compelled to be a witness; but the wife can be called in criminal proceedings made by or to the other spouse during the marriage. There is no such rule as to the husband. There may be no such rule as to the husband, and they may not be parties. If they, and the other parties are parties, they may be both witnesses, subject to the qualification as to not being bound to disclose communications made by or to each other during marriage. There is no rule as to the husband.

As regards all proceedings instituted against either husband or wife, the other spouse is neither competent nor can be compelled to be a witness; but the wife can be called in criminal proceedings made by or to the other spouse during the marriage. There is no such rule as to the husband. There may be no such rule as to the husband, and they may not be parties. If they, and the other parties are parties, they may be both witnesses, subject to the qualification as to not being bound to disclose communications made by or to each other during marriage. There is no rule as to the husband.

2. As to the property of the married persons. As regards the husband, he still remains sole owner of his property, real and personal, and can do what he likes with it; and he may, as already stated, by will devise and bequeath it all to strangers, regardless of the wife. He can also sue and be sued as before, irrespective of his wife. But as regards the wife, the case is different. Owing to her incapacity to contract or even to hold personal property independently of her husband, she cannot sue nor be sued except so far as her case has been settled upon her, as afterwards explained. If she had personal property before marriage, the whole —with a few exceptions—becomes the sole and absolute property of the husband. If she has none, the same is true before the marriage, if there is no marriage settlement. All debts which were due to her before marriage
HUSBAND AND WIFE

also become after marriage debts due to him, provided he choses to reduce them into possession, and sue for them. As a general rule it is, therefore, the wife may never sue in her own name for anything; even if she were to earn money as wages by her own personal exertions, she cannot sue for them without her husband being joined as a party, nor can she even take or sue for a legacy left to her without her husband, unless it was expressly left to her separate use. The only difference as regards the right of suing is, that where the debt was due to her before marriage, or the money claimed has been earned by her during marriage, both she and her husband may sue for it, or he alone must sue for it, according to circumstances, but when recovered, it belongs to him absolutely. In like manner, when the wife was in debt before her marriage, the husband, who in effect marries her debts also, must be sued jointly with her; and so, if she committed some wrong, as a slander or assault, the husband must be sued jointly with her; but where she merely ordered goods which were supplied to the husband, he alone is liable, and he alone can be sued. When the wife is properly sued along with the husband, both can be imprisoned if the debt is not paid; but the wife will be immediately discharged, as a matter of course, in comparison to the husband, provided she has no separate property of her own out of which the debt can be paid. The above rule as to the wife’s personal property becoming the husband’s absolutely after marriage, suffers a modification when such property consists not of money or chattels, but of what are called chattels real, such as leases and mortgages. In such a case, they become so far the property of the husband, that he can sell them during his life, but he cannot bequeath them by will; and on his death they remain hers, while on her death they become his. Again, where the wife’s personal estate before marriage consisted of mere rights of action or debts due to her, they are so far his that he can at any time sue for them, and in effect reduce them into possession, and make them his own absolutely; but he cannot bequeath them by will; and if he do not sue for them in his lifetime, they survive to the wife after his death. As regards the husband’s estate, i.e., her lands and houses held in freehold—the husband does not acquire these absolutely by the marriage, but he thereby becomes entitled to a life-estate in them. He cannot sell the property absolutely, but he may sell his own life-estate in it. On the other hand, though the real estate still continues to belong to the wife, she cannot sell it, like an ordinary owner, unless she separately acknowledges the deed of sale, which is done by her going before a commissioner or a judge, who examines her in private, and explains the nature of the deed, and sees that she understands its purport, and that she acts freely, without the coercion of the husband.

On the death of one of the married parties, the property is disposed of as follows: if the husband dies, his will may, as already stated, dispose of his whole property to strangers, irrespective of the wife, and she may be left entirely destitute in consequence; but there are some things he cannot do, in such a case. He cannot take away from her, as, for example, her leases, mortgages, choses in action, and her real estate. To these may be added her paraphernalia, which consists of her personal apparel and jewels; but even these will be taken by her husband’s creditors, if there is a deficiency of assets. If the husband die without a will, the law is more liberal to the widow; she is entitled to one-third of the husband’s personal estate absolutely, and not merely to a life-interest in it; she is also entitled to dower out of her husband’s real estate, i.e., to a life-interest of one-third of the whole real estate which belonged to him. This right of dower, however, can in general be defeated by the husband’s will. When the wife dies before the husband, he becomes entitled to nearly all her personal estate, of whatever description, even though she leaves children of the marriage; and it must be remembered that she can in no case make any effect, if the husband chooses to repudiate it. As regards the wife’s real estate, if a child has been born, who might by possibility have inherited her real estate, then the husband has, by the courtesy of England, an estate for life in the whole of such real estate; but if no child has ever been born, the real estate goes to the wife’s heir-at-law, or if none, to the crown.

The common law of England has been often considered, especially of late years, as unjust to women, in subjecting them too much to the caprices of their husbands. There are, however, several ways of avoiding this, but they are only available, as will at once be seen, to the rich. The most obvious effect of preventing the husband having powers so absolute as the law gives him, is by executing a marriage settlement before marriage. By means of a settlement, not only all the property which the wife has before marriage, but all which she or the husband can acquire during their lives, must be settled upon her to separate use, and put entirely out of the power of the husband. This is done by the agency of trustees, who hold and manage her property as their own, keeping the husband at arm’s length, and yet she has almost the same power of acting independently as if she were not married: she can draw her rents, keep her bank-account, enter into contracts, and bond her property absolutely, and sue in her own name, as if she were a man. Sometimes the husband and wife both settle their property by the same settlement; or if the wife has no property, the husband may settle her upon it in the same way. She is in that case generally allowed a certain sum per annum as pin-money, to spend upon her personal adornment; and by means of her trustees, she can sue her husband for this sum, if not punctually paid. Sometimes, by the marriage settlement, if the husband has any property himself, he can settle upon his own, so that he has a certain allowance per annum; but in the event of his becoming insolvent or bankrupt, the money is not to go to his creditors, but is to be retained by his trustees to pay her. It practically limits the variety of mutual arrangements which can be made by means of a marriage settlement, which can always mitigate and provide against the possible hardships of the common law. It is on the same principle that, in some cases, the Court of Chancery has interfered to prevent the husband acquiring so absolute an interest in the wife’s property as the common law gives him. Thus, if a legacy or other property has been left to a wife, and he has made no other provision for her, the court will not pay the sum to him until he has settled the same upon her and the children; but this is only done when the legacy or other property exceeds £200. It may also be mentioned, that a person who acquires property by marriage becomes a legacy to a married woman, so that the husband shall not take it; this is done by simply adding the words ‘for her separate use, independently of any husband.’

When a marriage is once contracted, the parties cannot of themselves, or by any arrangement they can enter into, put an end to it; nothing can do this but a divorce, or the death of one of the parties. It is a solemn and not uncommon among this wedding classes, that if one of the parties runs away or disappears, the marriage is at an end, and the party
left behind may, at least after a time, marry again. This, is however, not the case. It is true, that if of one of the parties has not heard of the other for seven years, and has reason to believe that that other is dead, the former cannot be convicted for bigamy in marrying again. But this is merely an excuse for escaping the usual punishment; the second marriage only remains good if the first party is really dead, or never turns up again. If at the law does not independently insist that he be dead before the first marriage is dissolved, the first marriage still remains good, and the second bigamous marriage becomes a nullity, and the children born of it, if any, are bastards, so that so long as both parties live, the only way of dissolving the marriage, so as to permit either to marry again, is a divorce, which can be obtained only on certain grave grounds. There is an intermediate state, called Judicial Separation (q.v.), which can be brought about for certain grave grounds less than what would warrant divorce. But though a wife judicially separated may enter into contracts, and is, as regards her dealings, much the same as an unmarried woman, she is still a wife, and cannot marry again; and if the parties are not living separately by mutual agreement, they are nevertheless married, and have most, though not all, of the rights of married persons.

Scotland.—The law of husband and wife in Scotland as regards their personal rights and duties, and the property during the marriage, does not differ essentially from that of England, except that the law ofnullity of marriage and divorce is substantially different. In Scotland, the nullity of marriage is called Goods in Communion (q.v.); but this phrase has no meaning except with reference to the principle of the extinction of the personal estates of the parties, and the dissolution of the marriage. As long as the parties live, the husband is, as in England, entire master, except that he cannot on deathbed bequeath more than a share of the property away from the wife. The same rule exists that the wife’s movable property becomes the husband’s, and her heritable property remains her own, subject to the husband’s life-rent. When she disposes of her heritable property by deed, she must also judicially satisfy the deed before the magistrate, and acknowledging that she acts of her own free will. When the husband deserts her, the wife may now in Scotland, as in England, obtain a judge’s order to protect her earnings and monies; and when a wife succeeds to property, whether her husband nor his creditors can take this until a reasonable provision has been made for her out of such property. (Conjugal Rights Act, 24 and 25 Vict. c. 86, sect. 1–5, 16.) A wife has, in Scotland, the same implied power to bind her husband for necessaries; but in Scotland the husband can, by a process of inhibition, give a general notice to tradesmen not to supply her at his expense, and this notice will be binding on all the Queen’s subjects. Notice that the husband was married in England would have so strong an effect; but even in Scotland such a notice as inhibition does not prevent the wife ordering necessaries, if not otherwise supplied. A rich wife is bound, in Scotland, to maintain her husband out of her estate, not but so in England. In Scotland, as in England, the rights of the parties may be varied by an ante-nuptial contract or marriage settlement; but there is less necessity for it, for the common law makes a provision for the wife in spite of her husband, inasmuch as he cannot by will bequeath away from her more than a third or half of his movable property respectively, according as there are children or no children. See Goods in Communion,Will.

In Scotland, as in England, the married parties may also execute a post-nuptial contract, which will be binding if the husband was solvent at the time of executing the contract, but though in England it will be in that case valid both as against wife and children and creditors, yet in Scotland it will bind the wife and children only if they thereby get a better provision than they would have been entitled to in any event, unless the court orders otherwise which they accept as equivalent. And, as a general rule, nothing can be done after marriage by the parties so as to set the property on either party, if the effect is to defeat their then creditors. The Scotch widow’s terce corresponds to the English widow’s dowry, and the rule as to the paraphernalia is not substantially different. The law as to the dissolution of the marriage and bigamy is the same in Scotland, though the grounds of divorce are more liberal in Scotland. See Divorce. Paterson’s Compendium of English and Scotch Law.

HUSBANDRY, SERVANT IN, a description of agricultural servant. Such a servant differs from ordinary domestic servants in this, that if the servant in husbandry leave his or her work without cause, &c., he or she can be punished for contempt of court on proceedings before a justice of the peace. This is so in all parts of the United Kingdom.

HUSKISSON, William, an eminent English statesman, was born at Birch Moreton, in Worcestershire, 11th March 1770, and in 1783 was sent to Paris to study medicine. He took part in the storming of the Bastille, and as a member of the Club of 1789, attracted attention by a number of speeches on subjects of political economy. In 1792, he returned to England, received a subordinate appointment under the Tory government, and formed an intimate acquaintance with Pitt and Canning. In 1793, he was selected by Dundas, the war minister, to be first under-secretary; and sat in parliament for Morpeth. He subsequently held several offices under Pitt, with whom he retired in 1801, and on the dissolution of parliament in 1802, lost his seat in the House of Commons. In 1804, he was returned for Liskeard, and was appointed secret at the new laws, built the new Pitt cabinet. On Pitt’s death, however, in 1806, he lost this office, but was restored to it by Mr Percival in 1807. He sat for Harwich, 1807—1812; Chichester, 1812—1825; and Liverpool, 1825—1830. In 1818 he was chief of the Woods and Forests; in 1822, president of the Board of Trade; in 1827, secretary of state for the colonies; and in 1828, secretary of state for foreign affairs. But this office he resigned, and retired from the ministry the same year. Through his exertions the old restrictions on the trade of the colonies with foreign countries were removed. He also obtained the removal or reduction of many import duties, considerable relaxation of the navigation laws, and is allowed to have been the great pioneer of free trade. He received fatal injuries at the opening of the Liverpool and Manchester Railway, 15th September 1830, and died the same evening. A collection of his speeches was published in 1831. Both from the comprehensiveness of the views which they exhibit, and their fulness of accurate details, they are interesting to the student of political economy.

HUSS, John, the Bohemian reformer, whose name is associated with that of Jerome of Prague (q.v.), both on account of the work which they wrought, and the death which they suffered, was born in 1577 at Hussinen, near Prachatice, in the south of Bohemia. He studied at the university of
HUSSAR—HUT

Prague, where he soon made great progress in the branches of learning most valued in that age, took his degree of Master of Arts in 1308, and began to lecture publicly in 1309. In 1402, he became preacher in the Bethlehem Chapel in Prague, and laboured with the greatest earnestness for the instruction of the people, and in the discharge of all his clerical functions. As a preacher, he was generally acquitted both by the common people and by the students; whilst as confesser to Queen Sophia, he obtained access to the court. At this time he became acquainted with the writings of Wickliffe, which exercised a great influence over him. The monks and clergy were of course violent enemies to H., as he denounced, with continually increasing boldness, their corruptions. Archbishop Sibiko burned the writings of Wickliffe in 1410, in compliance with a brief of Pope Alexander V., and complained to the pope of H., as a Wickliffeite. Hereupon he was summoned to Rome; but he did not go, and the combined influence of the people, the court, and the university, compelled the archbishop to remove a prohibition which he had issued against his preaching. But in 1412, Pope John XXIII., having published a bull of indulgence in order to a crusade against Ladislaus, the excommunicated king of Naples, whose kingdom the pope claimed as a part of the empire, boldly raised his voice against the whole procedure as unchristian, whilst Jerome of Prague also stood forth to condemn, in the strongest manner, both the bull and the vendors of indulgences. An interdict against H., in 1413, was the consequence. H., however, appealed from the pope to a general council and to Christ, and wrote a book, On the Church, in which he condemned the abuses of the papacy, and denied the unconditional supremacy of the Roman pontiff. Thinking himself no longer safe in Prague, he now retired to his native place, where he preached the gospel with great power. In 1414, he went to Constance to the general council, summoned thither, indeed, on a charge of heresy, but under the protection of King Wenceslaus, and having a safe-conduct from the Emperor Sigismund. Having reached Constance on the 3d of November, he was, on the 26th of the same month, apprehended in spite of the remonstrances of the Bohemian and Polish nobles. His trial was conducted with little regard even to the appearance of equity. On the 6th of July 1415, thirty-nine charges were exhibited against him, some of which he acknowledged as exhibiting his doctrine, while others he utterly denied. Being required to recant his alleged errors, he refused to do so till they should be proved to be errors. He and his writings were now condemned to the fire, and in spite of his safe-conduct, the sentence was carried out on the same day, and the ashes of the martyr were thrown into the Rhine.

HUSSA'r, a light-cavalry trooper, dressed in a loose jacket, with other articles of attire easy in set, and a fur cap; armed usually with a sabre and pistol. The idea of these troops, now in every army, came originally from Hungary. There are 13 regiments of Hussars in the British army (1862—1863).

HUSSITrES, the followers of Huss (q. v.). Honouring him and Jerome of Prague as martyrs, they despised the decrees and anathemas of the Council of Constance, took terrible revenge on the priests and monks. The symbol of their confederacy was the cup, the use of which in the Lord's Supper they extended to the laity, as James de Misa had already done with the approbation of Huss. In 1417, King Wenceslaus took steps to prevent their use, and it ever after was confined to the use of many churches. After his death, 13th August 1419, the majority of the states refused to acknowledge his brother, the Emperor Sigismund, who had broken his safe-conduct to Huss. And the papal instructions to the Cardinal Legate, John Hunyady, requiring him to employ violent measures for the conversion of the Hussites, an insurrection ensued, and the war began which is known in history as the Hussite War. Convents and churches were reduced to ashes, and priests and monks were slain. The Hussites divided into two parties—the more moderate known by the name of Calixtinenses (q. v.), and the more extreme by that of Taborites (q. v.).

HUSTINGS (of doubtful derivation), a place or temporary platform where members of parliament are formally proposed or nominated for election.

HUSUM, a small town of Denmark, in the province of Slesvig, and 22 miles west of the town of that name, is situated on the coast of the North Sea, at the mouth of a small river. It was formerly strongly fortified, and possessed many ships. Pop. 2079, who manufacture leather and tobacco, and carry on distilleries and breweries, and some trade in wool and cattle.

HUT, in army affairs, is a wooden structure, more or less rough in its details, for the housing of troops. It is substituted very often for the tent, when the sojourn in a camp or cantonment is likely to be of consideration, as, for instance, through a winter—a hut, however rude, which is wind and water tight, being as superior in comfort to a tent as the latter is to the open air. Huts may be made of almost any size, and are sometimes for one officer; at others, for as many as 100 men. The principal hut encampments at present in the United Kingdom are at Aldershot, Shorncliffe, Colchester, and the Curragh of Kilbride; in British North America, hut-camps are situated at intervals of a day's march on the route from New Brunswick to Quebec, and the troops who made that winter-march in 1861—1862, found their shelter truly welcome.

As the hut is as useful to the settler in a wild country as it is to a soldier, we give some of the particulars of their manufacture in different forms. Huts are of four sorts: 1. The log hut; 2. The framed hut; 3. The peel hut (of tempered clay).

The log hut is formed of rough logs or trunks of trees, laid crosswise in tiers to the required

Fig. 1.
by a stuffing of clay, wattles, sawdust, or small bundles of twigs. Within, the joints should be lined with rails, or the whole interior may be boarded with inch-planks, if such are attainable. The roof should be supported by a scantling (see Root), and may consist of overlapping boards, or boards laid flush and shingled, or rails and shingles, or even birch-bark alone. The door is usually ledged, and there are one or two windows, with glazed sashes and shutters. These should be made by regular carpenters, and taken to the place of building ready for use. A hut thus formed makes a snug habitation, and will last for many years; exclusive of the sashes, two men can erect, in about a week, a hut of rough logs which shall be sufficiently large for their residence—that is, with an interior area of about 15 feet by 10 feet.

When circumstances permit, the logs are occasionally squared, which enables them to be fitted more accurately to each other, and adds, of course, to the solidity and finish of the whole structure, as well as to its durability. In this case, the corner logs, instead of crossing each other, are joined by a dovetail, or by cutting the end of each to an angle of 45°.

The framed hut has the advantage over the log hut of allowing more exactness of finish, and from its lightness and portability being easily transported to any place where logs for hut building might not be forthcoming. It consists of a strong framework of squared wood, properly fitted together, and covered with overlapping planks or weather-boards. The side of a framed hut is shown in fig. 12. The plates should be sawn to the proper size, fitted to each other, and numbered; then packed together in small compass for conveyance to the intended site, where the structure can soon be erected. No one piece need exceed 11 feet in length, 6 inches in breadth, and 2 inches in depth. The uprights should not be more than from 15 inches to 18 inches apart, and should be firmly held by diagonal tie-rods, as in the illustration. The first step is to carefully level the ground on which the hut is to stand, and if a dwarf-wall of stone or brick, 8 or 10 inches high, can be built round, so much the better. On this ground or wall a rectangular frame of thick wood (say 6 inches by 3) must be laid as a basis for the framework; on this latter the uprights are placed, the binding tie-rods fixed, and the cap-ends, corresponding to the frame below, placed above all, every joint being carefully mortised and tenoned. The weather-boards can now be nailed on the outside, and when the roof is put on, the hut is complete. The breadth should not, for stability, exceed 16 feet; and when the hut is of any considerable length, cross-beams should be thrown from side to side at the top. The roof should be made of ordinary scantling, as described under Root. It is usually estimated that one of these huts, 30 feet long, 16 broad, and 10 high, makes a good barric-room for 20 soldiers. The camps at Aldershot and the Curragh are mainly formed of framed huts. Where extra warmth is desired, the spaces between the uprights are built up roughly with bricks, burned or unburned.

Pist huts, common in the south of France, and very useful where wood is scarce, as well as very comfortable, are walled with blocks of chivey earth, compressed with great pressure into wooden moulds until they assume the forms of stones. These are laid one above each other much as stones themselves would be by a mason, and the wall so formed is both durable and slight.

The most critical operation for the non-professional hut-builder is roofing. This is usually of thatch, shingles, paper, or felt, if lightness be an object; and of stones, bricks, or tiles, if the walls be calculated to bear their pressure.

HUTCHERSON, Francis, a distinguished philosopher of last century, was the son of a Presbyterian minister in the north of Ireland, where he was born in 1694. He studied for the church at the university of Glasgow, but shortly after the completion of his theological course, he was induced to open a private academy in the city of Dublin, which proved highly successful. In 1729, he published his Inquiry into the Original of our Ideas of Beauty and Virtue, &c., which was the means of introducing him to the notice of many influential personages, such as Lord Granville, the then lord-lieutenant of Ireland. After his success, he became the bishop King, Primate Boulter, and others. This work was followed, in 1729, by his Essay on the Nature and Conduct of the Passions; and in the year after, he was appointed professor of moral philosophy in the university of Glasgow. Here he died in 1747. His largest and most important work, A System of Moral Philosophy, was published at Glasgow in 1750 by his son, Francis Hutchinson, M.D., with a Preface on the Life, Writings, and Character of the Author, by Dr Leechman, professor of divinity in the same university. As a metaphysician, H. may be considered a pioneer of the so-called 'Scotch school.' From the period of his lectures, according to Dugald Stewart, may be dated the metaphysical philosophy of Scotland, and, indeed, the literary taste in general, which marked that country during the last century, although, as Stewart acknowledges and Hamilton shews, traces of the Scotch philosophy appear in the earlier writers. But it is as a moral philosopher, rather than as a metaphysician, H. shines. His system is, to a large extent, that of Shaftesbury, but it is more complete, coherent, and clearly illustrated. H. is a strong opponent of the doctrine, that benevolence has a selfish origin. The faculty by which moral distinctions are recognised, H. (after Shaftesbury) terms a moral sense. See Ethics.

HUTCHINSON, John, an English theological writer, born 1674 at Spennithorne, in Yorkshire. He was for some time steward of the household of the Duke of Somerset, and left his service to devote himself to his religious studies, the duke procuring for him a sinecure appointment of £200 a year from government. In 1724, he published the first part of a work called Moral Principles, in which he defended what he regarded as the Mosaic cosmogony, and assailed Newton's theory of gravitation. He continued to publish a succession of works till his death, which took place on 28th August 1737. His religious system is best exhibited in his Treatise concerning Religion. The leading principle of it is, that the Holy Scriptures contain the elements not only of true religion, but of all rational philosophy, which, however, he is determined to be derived only from the original Hebrew; and it, for that purpose, was subjected to strange critical or rather fanciful processes.
HUTCHINSON—HUY.

His works at one time exercised a considerable influence. His followers were called HUTCHINSONIANS, and were so strange as it may be seen—were persons of considerable learning and celebrity.

HUTCHINSON, ANDREW, a religious enthusiast, of American celebrity, emigrated from Lincolnshire, England, to Boston, Massachusetts, in 1636. Living in a community prone to religious excitement, she clung to a sort of divinity of diviner revelations, and held meetings for women, in which she held forth Antinomian doctrines. Great controversies arose, and a synod was called, in which her teachings were condemned, and she was banished from the colony. She and her friends now obtained from the chief of the Narragansett liberty to reside in Rhode Island, where they set up a community on the highly commendable principle, that no one was to be 'accounted a delinquent for doctrine.' After the death of her husband (who shared her opinions), she removed to a Dutch settlement, in the colony of New York, where, in 1643, she and her whole family of 15 persons were taken prisoners by the Indians, and all but one daughter barbarously murdered.

HUTTEN, Ulrich von, famous in the history of the Reformation, was descended from an ancient and noble family, and was born at the family castle of Steckelberg, in the electorate of Hesse, April 1488. When he was ten years of age, he was placed in the monastery at Fulda; but disliking this mode of life, he fled to Erfurt in 1504, where he associated with scholars and poets. He then lived at various places in Northern Germany till about 1512, when he went to Pavia to study law. After passing several years in Italy, he returned to Germany, and made himself conspicuous by his publications, especially those concerning the affair of Reuchlin and the Dominican Hoogstraten, in Cologne, in which he came to the support of Reuchlin, and displayed no small learning and great power of satire. He again went to Italy in 1516, to take the degree of Doctor of Law, and returned to his native country in 1517. He was crowned with the poet's laurel crown at Augsburg, and the Emperor Maximilian conferred on him the honour of knighthood. In the same year he edited a work of Laurentius Valla, found in a convent, De Fidei Credibilitate et Eternitate Donatone Constantini Magni, and in 1518 accompanied Albert, Archbishop of Mints, to the diet of Augsburg, where he became famous for his conversation with Cajetan. Subsequently, he established a small printing-press of his own, and employed himself in writing and disseminating pamphlets fully exposing the arrogance and wickedness of the Romish clergy. The Archbishop Albert denounced him to Rome, wherupon he entered into an immediate and avowed connection with Luther, whom he had hitherto despised. At this time, also, he began to write in the German language, instead of Latin. Persecuted by his enemies, he availed himself of the protection of Franz von Sickingen, but was soon forced to flee. From this time H. was compelled to adopt a wandering life, and died 31st August 1525, in the Isle of Ulmam, in the diocese of Zürich. He was bold and more open in the expression of his opinions than almost any man of his age. He did much to prepare the way for the Reformation, and to promote it. It may be attributed to him as a fault, that he was too reckless of consequences, and not sufficiently tender in dealing with things that had become venerable in the eyes of many; but he was a man who feared nothing, even when almost all his friends deserted him. He was a master of the Latin language. He left 45 different works, of which a collective edition was published at Berlin in 1821—1827, in 6 volumes. The best life of H. is that published at Leipzig, in 1857, by Dr David Friedrich Schleiermacher.

HUTTON, Charles, an eminent mathematician, was the son of a superintendent of mines, and was born at Newcastle-upon-Tyne, 14th August 1737, and in 1755 became teacher in a school at Jesmond, and afterwards at Newcastle, till 1773. During this period, he published his Treatise on Arithmetic and Book-keeping (1746); Treatise on Mensuration (London, 1771); and Principles of Bridges, and Mathematical Demonstration of the Laws of Arches (Newcastle, 1772). In 1773, he was appointed to the professorship of mathematics at the Royal Military Academy, Woolwich, and in November 1774 was elected a fellow of the Royal Society. Soon after this, he was selected to perform the necessary calculations for determining the density of the earth from Dr Maclaurin's model of Schichallian, and his report was published in the Philosophical Transactions for 1778. In 1779, he received the degree of L.L.D. from the university of Edinburgh, and a diploma in geology from the Royal Society, in 1781; and in 1783, his most important works are—Tables of Products and Powers of Numbers (London, 1781); Mathematics Tables (London, 1785); Mathematical and Philosophical Dictionary (London, 1795); Course of Mathematics (London, 1798—1801); and Recreations in Mathematics and Natural Philosophy (4 vols, London, 1803); the last being a most interesting and instructive work. Besides these, he regularly contributed mathematical papers to the Ladies Diary, of which he was for some time editor, and also to the Philosophical Transactions. His biography has been written by Dr Olinthus Gregory.

HUTTON, James, a celebrated geologist, was the son of a merchant in Edinburgh, and was born there 31 June 1726. He studied in his native city, and afterwards at Leyden, where he took the degree of M.D. He devoted himself, however, not to the medical profession, but to agricultural pursuits and to the science of geology, from which he was led to geology and geology. He contributed much to the improvement of agriculture in Britain. He made some chemical discoveries, and is the author of a Theory of the Earth and of the Rocks of the Earth. His Theory of Earth has been since acknowledged by men of science as generally correct, although at first it met with some opposition. His Theory of the Earth has for its distinguishing feature the supposed agency of a central heat which has, at elevation of strata, and has been converted into the forms and structures of the earth. It has been the subject of much discussion and crystallisation. Dr H. was indeed too extreme in his theoretical views, and some of his followers were still more so. He was, however, not only a great observer in geology, but a great observer in geology, and his discovery of granite veins is of no small importance in the history of that science. He died March 26, 1797.

HUY, a strongly fortified town of Belgium, in the province of Liége, is romantically situated amid a group of hills on that he was of the Meuse, and in the immediate neighbourhood of the finest scenery of that river, 17 miles south-west of Liége. Its citadel, the works of which are partly excavated in the solid rock, commands the passage of the river. The principal church, dedicated to St. Michael, and the other edifices, was begun in 1311. In the vicinity are iron-works and coal-mines, in the products of which the
inhabitants carry on a lively trade by means of the Lisse and Namur Railway. The principal manufactures are paper, leather, beer, spirits, and an inferior kind of wine. Pop. 10,011.

Peter the Hermit, on his return from the first Crusade, found the city of Antwerp inhabited by a number of monks (Novum Monasterium), and was himself thereby attracted to it. H. has been frequently taken during the wars, of which this region has been the seat. It was last captured by Marlborough and Coecroft in 1706.

HUYGENS VAN ZUYLICHEM, Christian, one of the great philosophers of the 17th century, was born at the Hague, April 14, 1629, and was the second son of Constantijn Huygens, secretary and counsellor to the princes of Orange. H. studied at Leyden and Breda. His first work, *Theorematum de Quadratura Hyperboles, Ellipsis, et Circuli, ex Data Portionum gravitatis Centro* (Leyden, 1651), is an example of that powerful geometrical talent which lay at the foundation of all his scientific achievements. Soon after this, he constructed the pendulum-clock, following out the idea first suggested by Galileo (q. v.). A complete description of H.'s instrument is contained in his great work, *Harmonia macroscopica, seu de Motu Pendularum* (Hague, 1658).

This work contains expositions of many of the cases of constrained motion, especially those applicable to the construction of time-pieces. It was also developed and given precision to the investigations of Galileo upon accelerated motion under the action of gravity; and there is no doubt, that to the clearness of his demonstrations, his great success, Newton, in preparing his magnificent development of the principle of accelerating force, was largely indebted. Newton was a student and admirer of his works, and assigns to him, along with Sir C. Wren and Wallis, the distinguished epithet of *hujus artis geometricae facile princeps.*

By means of an improved telescope of his own construction, H., in 1655, discovered the ring of Saturn and the fourth satellite of that planet. In 1659, he published an account of these discoveries in his work *Systema Saturnium, seu ex Causis Motuum Saturni Phenomeno, et Comite ejus Planetis Novo.* In the end of this work is described an invention of great importance in astronomy—namely, the Microscopium (q. v.), by which the angles between objects viewed by a telescope are accurately measured. In 1660, H. visited England, where he was admitted a member of the Royal Society. He discovered the laws of collision of elastic bodies about the same time with Wallis and Wren, and also made a material improvement in the air-pump.

In 1666, H. received an invitation to settle in France, with the promise of a pension from Colbert, then all-powerful in that country. He repaired to Paris, where he remained till 1681, having been admitted to the membership of the Royal Academy of Sciences; but alarmed at the danger which seemed impending over the Protestant, he returned to his own country. After his return, he still continued his favourite pursuits till his death at the Hague, 9th June 1693.

The optical works of H. lastly claim our attention. They are chiefly remarkable for his maintaining a theory of light, which, opposed as it was to the then more popular theory of Newton, is substantially the same with that which is now called the *electrostatic theory.* By means of his hypothesis, he explained the ordinary phenomena of reflection and refraction, and further succeeded in a satisfactory explanation of the phenomenon of double refraction, which Newton's theory failed to account for.

HUYSUM, Jan van, a celebrated Dutch painter of flowers and fruits, was born at Amsterdam in 1632, and acquired the rudiments of his art from his father, a landscape-painter of very considerable talent. H. surpassed all his predecessors in mellowness, purity, and delicacy of colouring; the exquisite disposition of his lights and shadows; and above all, in his miraculous rendering of dew-drops and the motions of insects. He died at Amsterdam in 1749. H.'s master-pieces are to be found in the galleries of Vienna, Munich, and St. Peterburg.

HWANG-HO, HOANG-HO, or YELLOW RIVER, one of the principal rivers of China, about 2400 miles in length, the area of its basin being not less than 700,000 square miles. It rises in a marshy plain lying between the Bayan-kara and Kwanlun Mountains, in a lake called Ala-nor, in lat. 35° 30', long. 96° E. Its course is so crooked that, after it leaves Ala-nor, it turns first south 30 miles, then east 160, then westward 120, winding about the gorges of the Kwanlun, then north-east into the province of Kansu, where it proceeds northward for 430 miles, till it is bent easterly by Inshan, on the edge of the table-land, where it encloses within its great bend the country of the Ortoos Mongols. At the Peh-liung it is deflected south, where it divides the province of Shansi for 500 miles. At the south-western corner of Shansi, it receives its largest tributary, the Wei-ho, 400 miles in length; from this point the Yellow River flowed until recently easterly to the ocean, 650 miles distant, in lat. 34° 4'; it is little used for navigation, Chinese vessels being unable to stem its impetuous current. In some parts of its eastern course, it is above the great plain through which it passes. The embankments requisite for averting inundations are a source of never-ending expense to the government, and their yielding to floods a frequent cause of desolation to extensive districts of country. Dr Macgowan announced lately, in the North China Herald, that this wayward and turbulent stream had suddenly shifted its course, turning off near Kaifung-foo in a north-easterly direction, discharging its waters into the rivers of Chihile, which disembogue in the Gulf of Pohichele, the mountains producing excellent potatoes, and prevented by an intervening between its former and its present mouth, a distance by coast-line of about 500 miles. More recently, it was announced that the bed of the Yellow River, for some 100 miles from its mouth, was a belt of sand, which, since the spring of 1853, has been, to use the Chinese term applied to it, 'as dry as dust.' The change seems to have been gradual. As there were frequent slight shocks of earthquakes in the Great Plain of China in 1852–1853, Dr Macgowan suggests that these contributed to effect the phenomenon, another cause being neglect of the dykes by the imperial government. Its present channels are not precisely known, but they are probably the same as in ancient times; for it has shifted its bed at different periods of Chinese history. The vast quantity of sediment conveyed to the sea by this river, giving it its colour and name, is taken up in that part of its course which lies between the provinces of Shanse and Shensi; beyond that region its waters are remarkably clear.

HYACINTH, a name given to the brilliantly coloured varieties of the gem called Zircon (q. v.); also to fine flowers of the genus Charmoula (q. v.); and sometimes to ferruginous quartz of a blood-red colour, which, from its occurring abundantly in gysum at Compostella, in Spain, is called *H. of Compostella.*

473
HYACINTH—HYENA.

HYACINTH (H. hyacinthus), a genus of plants of the natural order Liliaceae; bulbous-rooted plants with corolla-like, bell-shaped, 6-cleft perianth, six stamens fixed in the tube of the perianth, and dry cassisular fruit.—The Oriental H. (H. orientalis), one of the most frequent of florists' flowers, is a native of Asia Minor, Syria, and Persia. It is now naturalised in some parts of the south of Europe. It has broad linear leaves, and a scape with a raceme of many flowers pointing in all directions. The flowers in cultivation exhibit great variety of colour, chiefly blue, purple, and white. They are very beautiful and very fragrant. The fragrance is strongest about an hour after eleven o'clock at night. Among cultivated hyacinths, there are many with double flowers. The H. has been cultivated from a remote period, but about the beginning of the 18th c., it attained almost the first place as a florists' flower. Great attention was bestowed on the production of new varieties, and enormous prices were given for bulbs of some of them. A price equal to £200 sterling was sometimes paid for a single bulb. The principal seat of the cultivation of hyacinths was and still is at Haarlem. At present it, however, more than £10 is seldom asked for the finest new variety of H., but although the trade is considered as now much depressed, the Haarlem gardeners still sell bulbs to the value of £2000 or £3000 yearly. H. bulbs, planted in pots, readily produce beautiful flowers; and flowers almost equally beautiful are obtained—for one year, however, only—by placing them in water in H. glasses, in which they form a favourite ornament of apartments in winter and early spring. In cultivating the H. in this way, rain-water should be used for filling the glasses in preference to spring water. The roots should never be disturbed, if possible, and therefore the water should not be changed, but the glass must be filled up occasionally till it almost touch the bulb. A piece of charcoal may be placed in it to purify it. The glasses ought to be kept in a dark cool place till the bulbs have sent out roots. Hot rooms are apt to make the stems long and the flower-spikes small. The cultivation of the H. in the open ground is much more difficult, if the varieties are to be preserved from degenerating. A light sandy and yet rich soil is requisite. A compost of cow-dung, rotten leaves, and fine sand is used at Haarlem. New varieties are raised from seed. Several other species of H. are natives of the south of Europe, Africa, &c.—The Grape-Hyacinth and Globe-Hyacinth, frequently cultivated as garden flowers, are now referred to the genus Muscaria, of which the perianth is merely 6-toothed.—A common British plant, growing in woods and copses, with beautiful blue flowers very like those of the Oriental H., but all drooping to one side (H. non-scripta), also known as Scilla nutans, Eulophion nutans, and Aegropis nutans), is sometimes called the Wild H., and sometimes the Blue-Bell. The bulbs were used in the time of Queen Elizabeth for stenching the ruffs then worn, and the stench of them was otherwise used instead of paste or glue. The fresh bulbs are said to be poisonous.

HYENA, a genus of digitigrade carnivorous quadrupeds, included in the genus Canis by Linnaeus, but by some naturalists referred to the family Canidae, but now more generally to Verrucae, whilst the dentition connects it even with Fœlicis. Hyenas have six incisors and two canine teeth in each jaw, five molars on each side in the upper jaw, and four in the under. They seize an object with so firm a hold, that, among the Arabs, they are proverbial for obstinacy. The vertebræ of the neck sometimes become anklylosed in old hyenas. The hind-quarters are lower and weaker than the fore-quarters of the body, so that hyenas move with a shuffling gait. The body is covered with rather long coarse hair, forming a mane along the neck and back. The feet have each four toes. The claws are strong, fit for digging, and not retractile. The tail is rather short. Beneath the anus is a deep glanulæar pouch, contributing much to the offensive odour by which hyenas are characterised. Hyenas eat carrion, as well as newly-killed prey, and are of much use, like vultures, as scavengers, clearing away the last remnants of carcasses that if left to rot would greatly pollute the air. They sometimes attack cattle, especially if they fly, but rarely man, though they sometimes seize children. During the day, they hide themselves in caves, old rock tombs, ruined edifices, &c.; by night, they roam singly or in packs in quest of prey. They prowl about towns and villages, and often dig up corpses that have not been very deeply buried. This, together with their aspect and manners, has caused them to be generally regarded with horror, and very exaggerated accounts of their fierceness have been prevalent. Instead of being untamable, as was long the popular belief, they are capable of being very completely tamed, and are attached to man similar to that of the dog; they have even been used as watch-dogs. Hyenas are found only in Africa and the south of Asia, not extending to the furthest east of the latter continent.—The Striped H. (H. vulpinus or striato) is found both in Asia and Africa, and there are several varieties considerably different in size, colour, &c. The smallest hyenas are of the size of a large dog.—The Spotted H. (H. crocuta) inhabits South Africa. It is rather smaller than the largest varieties of the Striped H., but is more fierce and dangerous. It is called Tiger-wolf by the colonists of the Cape of Good Hope. Besides its ordinary howling, which it emits very freely in its nocturnal roarings, this H. often indulges in an expression of gratification or of some passion, resembling hysteric laughter, whence it has acquired the name of the
HYA-HYA—HYBRID.

LAUGHING HYENA. The general colour is ochry gray, with thinly scattered small round brown spots, and sooty muzzle and feet.—The Woolly H. (H. villissa) is a smaller South African species.

In consequence of the bones which hyenas eat, their ing formis usually reveals round flat plates, or plates of compact earthy fracture, the Albin gracium of the old materia medica.

HYA-HYA. See Cow TREE.

HYBERNATION. See Hibernation.

HYBRIODUS (Gr. hump-tooth), a genus of fossil fish, whose teeth and osseous fin-rays are found in all the Secondary rocks from the Trias to the Chead inclinations. The genus, with the small family of Hybelodonts to which it belongs, occupies a place between the Cestracions, with their pavement of flat crushed teeth, and the sharks with their sharp-pointed cutting teeth. The teeth of the Hybelodonts are conical, but broad and blunt; from the body of the tooth rises a large central cone, and several small lateral ones, decreasing in size as they recede from the principal cone. The enamel is strongly marked by transversal grooves, and the cut surface is scattered with longitudinal folds. The osseous rays of the dorsal fins are the only other preserved portions of these fossils. Like the Port Jackson shark, the H. had each of the two dorsal fins furnished with a large and strong spine, one third of whose length was buried in the flesh. Nearly fifty species of this genus have been described.

HYBRID (Gr. hybrid, from hybrids, extravagance, licentiousness) is the term applied by naturalists to the offspring of different but generally nearly allied species. It occurs frequently and must be distinguished from the word mongrel, which is applied to the offspring of different varieties of the same species.

M. Broca, whose memoir on Hybridity of Animals is the most complete that has yet appeared, remarks that this condition may be (1) natural, (2) excited (naturque), or (3) artificial. The first variety is such as occurs spontaneously amongst animals in their wild state; the second includes those cases in which domesticated animals, which would not naturally cross with one another, do so under the influence of man, and in opposition to their natural instincts; while the third variety is due to the artificial admixture of the male and female generative elements, and as far as is yet known occurs only in fishes, and in the vegetable kingdom.

The second variety is far by the most common and the most important. When the male of the species A can impregnate the female of the species B, it may happen that the process can be inverted, and that the male B can impregnate the female A. In other cases, however, while the male A can readily impregnate the female B, the male B cannot impregnate the female A. In the first case, the hybridity is termed bilateral; in the second, unilateral. The former is rare, and even when it does occur, the cross in one direction is more common and more productive than in the other. Thus, the ordinary mule, the offspring of the male ass and the mare, is much more readily obtained, and, physiologically, is less imperfect than the corresponding animal, the hinny, which occasionally results from the union of the stallion and female ass. See MULE, HINNY. Our domestic sheep and goats afford an example of the latter (unilateral) kind of hybridity.

The interest of the plant is that the seed and the sawe is frequently productive, while the union of the ram with the she-goat is always unproductive.

In the present state of our knowledge, it is impossible to predicate in what cases the crossing of different species will be productive, and in what cases it will be barren. While some closely allied species do not admit of a cross, other species far more removed from one another, not only yield hybrids, but even fruitful hybrids. There is, however, a limit, beyond which the chance of offspring becomes reduced to zero, and, according to Broca: 'If the crossing of animals of different genera is now an incontestable fact, there is no authentic evidence that offspring has resulted from the crossing of animals of different orders.'

Cases have been reported to exist, as showing that animals of different orders may cross, but none of them are satisfactorily established. The strongest apparent case of hybridity between different orders is that of the Jomarts, which were said to result from the union of the bull and the mare, or of the stallion and the cow. These jumarts were believed in from the time of Columella to that of Buffon, who fully investigated the subject, and found that they were mere hinnies—the offspring of the stallion and the she-ass. Among mammals, hybrids have been obtained between the different species of the genus Equus. So far as experiments go, the horse, the ass, the zebra, the quagga, &c., breed freely intergrade, but the degrees of their hybridity, and their offspring have not been fully determined. The dog has been made to breed with the wolf and the fox, the lion with the tiger, the he-goat with the sheep, the ram with the female reed-deer (Cervus Capreodons), and the hare with the rabbit. (See Professor Owen's article, 'Hybrid,' in Brande's Dictionary of Science, Literature, and Art.) A case has recently been recorded in The Times newspaper, in which a prolific union took place between a male miff dog and a lioness that had been brought up together.

Among birds, hybridity is not uncommon. The swan will breed with the goose, the grasse with the blackcock, the pheasant with the common fowl, the goldmunch with the canary, &c. Among reptiles, hybrid offspring has been observed between the toad and the frog. Among fishes, hybrids have been obtained by artificial impregnation between different species of the genus Cyprinus. Many hybrids have no propagative power, while in others it is so far limited as to admit only of reversion to the original specific form. When a hybrid possesses generative power, it can generally be readily with an individual of one of its parent stocks than with another hybrid like itself. The most remarkable example on record of generative power in hybrids is afforded by the experiments of M. Roux of Angoulême, who finds that he can cross hares and rabbits to any extent, and who has thus, by breeding leporides, established a new and lucrative department in agriculture. For a full account of these experiments, which are well deserving of a trial in this country, the reader may consult Brown-Sequard's Journal de la Physiologie, vol. ii. pp. 374—383. These experiments have inflicted a severe blow on the popular doctrine of the permanence of species. Experiments on the hybridisation of plants have been very far from confirming the hybrid origin of forms apparently intermediate between other species, and which were once regarded as probably hybrids produced in a state of nature. The interference of man is usually necessary to effect an intermixture, and in many cases in which it has been found possible, it is by no means of easy accomplishment. The structure of the inbreed, which appears to be very strong; and if pollen, both of the same and of another kind, is applied to the stigma of a flower, the result is the same as if its own pollen had been there alone. The hybridiser, therefore, must cut away the stamens of the flower of which
the pistil is to be impregnated, and carefully prevent all access of pollen other than that which he brings to it. Even with these precautions, it is found impossible to produce hybrids between some plants of the same family, and not very dissimilar.

Hybrid plants are said to partake generally of the characters of the male more than of the female parent. It is more certain that valuable results are often obtained as to size and abundance of fruit, brilliancy of flowers, hardiness, and other qualities. The question of the continued fertility of true hybrids is one having most important relations to the great questions concerning species. Some assert that neither among animals nor among plants are hybrids fertile for more than one or two generations, if kept by themselves; although they are readily fertile with either of the parent species, to which they become again assimilated. But this opinion is controverted, and the question must, of course, be decided by observation of facts, in judging of which, however, questions of no little difficulty must often arise as to what are and what are not different species.

The subject of the hybridisation of plants was first investigated, and with great care and very numerous experiments, by Köreuter, in the end of the 18th c., and has been more recently studied with much attention by Dean Herbert of Manchester, Van Mons, and particularly Gaertner.

HYDASPES. See JELUM.

HYDATID (from the Greek hydatis, a watery vesicle), a term indefinitely applied to several distinct objects of a vesicular or cyst-like character, which are found in the bodies of men and certain mammals. True hydatids were formerly regarded as cystic Eutozoa (q. v.), such as Cysticerus, Cernurus, and Echinococcus, but all these animal forms are now discovered to be larval stages of the true or Tape-worm (q. v.). These hydatids may occur in almost any part of the body, and they have been observed in man, the ape, the ox, the

sheep, the horse, the camel, the pig, the kangaroo, and some other vegetable feeders, but they appear to do not occur in carnivorous animals or in the rodents. They are generally enclosed in an external sac, which is attached to the tissue of the organ in which it is situated, and which is very frequently common to many hydatids, each of which has a distinct envelope. The fluid in the interior of the hydatid itself is almost always colourless and limp, but the fluid in the common cyst in which the hydatids float is often a yellow colour. The Cercarius cerebralis is found in the brain of various ruminants, and gives rise to the disease known as the Tapeworm disease. When the hydatid occurs in the fourth ventricle, the animal, instead of turning round and round in one direction, springs in the air, and this variety of the affection is hence distinguished by German veterinarians as das Springen. Whenever any of the above forms of hydatids are swallowed by the lower animals, they may proceed, under favorable circumstances, to be developed into the higher stages of tape-worm. Two species of Echinococcus are usually noticed, namely, the Cercarius mammillaris, which has been occasionally met with in the brain and abdomen of man, and the E. exterminans, which is of common occurrence in various parts of the body of the pig, and several other mammals, but it is by no means certain that they are really distinct. These Echinococci do not become developed into tape-worms unless they reach the intestinal canal of some animal, by being taken as food; and in order to develop into hydatids, compound Echinococci, the cysts and their contents undergo a kind of degeneration, becoming in some cases converted into fatty or calcareous matter, while in other cases the contents become granular, the peculiar hydatids (which will be described in the article TAPE-WORM) which occur in them, and which remain unaltered for a long time, revealing their true origin.

The so-called acanthocyst, or common globular hydatid, which sometimes attains the size of a child's head, is probably a degenerated or abnormally developed echinococcus.

Hydatids sometimes occasion so little inconvenience, that persons, in whom they are discovered after death, have not suspected any disease in the organ in which they are found. On other occasions, they grow rapidly, and cause so much irritation that suppuration is excited in or around the common sac, which may either burst externally, or into a mesenteric canal or a serous cavity. In the first or second case, the hydatids will be discharged, and recovery may take place; in the third case, fatal inflammation will ensue. Little can be done for the treatment of this disease, except that occasionally, if the cyst is near the surface, it may be carefully punctured. The means of preventing the affection will be noticed in the article TAPE-WORM.

False hydatids are simple serous cysts, either occurring alone or in clusters, whose mode of origin is not distinctly understood. Structures of this kind, on a small scale, are common in the choroid plexus of the brain, while on a large scale they are found containing the fluid in ovarian droplets. These false hydatids are also of comparatively common occurrence in the uterus, which they may distend to such a size as to simulate pregnancy.

HYDE, an important manufacturing town of England, in Cheshire, is situated seven miles east-southeast of Manchester, and about the same distance south-east of Oldham. Until a comparatively recent period, it was a mere village; but since the extension of the cotton-trade, on which it mainly depends, it has rapidly increased in size. Its population in 1861 was 13,722. Besides the numerous cotton-factories, iron, water, and print works are carried on. Coal abounds in the neighborhood. The district in which H. is situated is densely peopled, and is furnished with abundant means of
communication, by railway and canal, with all the important towns in the vicinity.

**HYDE—EDWARD.** See CLARENDON, E. of.

**HYDE PARK,** a noble enclosure of nearly 400 acres, extending from the western extremity of London to Kensington Gardens, which derived its name from having been the manor of the Hyde belonging to the Abbey of Westminster. It became the property of the crown on the dissolution of the monasteries, in the reign of Henry VIII. A canal or pool of water, called the Serpentine, although in the form of a parallelogram, was made in H. P., between 1730 and 1733, by order of Queen Caroline. At the eastern end of it is an artificial waterfall, constructed in 1817. On the south side are the barracks of the Life-guards. It was in H. P. that the great International Exhibition of 1851 was held, in a Crystal Palace specially erected for the occasion. We do not clearly learn at what time the public began to have free admission to Hyde Park. But Denison speaks of the show of coaches which it presented in his time; and we know that it was constantly resorted to on the morning of May-day for the sports comprehended under the term Maying. Till the middle of the 17th c. there was a part of it which contained deer. About that time, it began to be a place for races and military reviews. It was also resorted to for duels. After the Restoration, it appears to have become the favourite promenade, which it has ever since continued to be. It has, however, undergone many changes of boundary and division; large part of Kensington Gardens have been taken from it, also an angle at the southern corner on which Apsley House now stands.

**HYDER ALI,** ruler of Mysore, and one of the greatest Moghul Princes of India, was born in 1728. His father, who was a general of the Rajah of Mysore, afterwards obtained Bangalore in feud, and both of these honours descended to his son. H. A., in 1739, dispossessed his master, allowing him, however, to retain his title, while he himself took that of dater, or regent. He then conquered Calicut, Belniur, Onor, Cannanor, and other neighbouring states; and in 1766, his dominions included more than 800,000 square miles. He invaded two wars against the British, in the first of which he was completely successful, and dictated terms of peace under the walls of Madras, but died before the termination of the second, in which he was aided by the Nizam, a native confederacy for the expulsion of the British from India. He, besides, withstood the customary tribute from the Maharattas (q. v.), and waged a successful war against them. In his wars he displayed great resolution and perseverance. He died in 1762. H. A. was remarkable amongst Asiatic princes for the mildness of his character and government, and was much beloved by his people. He promoted agriculture, commerce, and the arts, and protected all religions, requiring only submission to his laws. His son and successor was Tipoo Saib (q. v.).

**HYDERABAD,** more properly HYDAKABAD (from Haidar, lion; and bad, town), the capital of the Nizam's Territories (q. v.), stands on the right bank of the Musi, in lat. 17° 22′ N., and long. 78° 22′ E., at an elevation of 1800 feet above the sea, and contains, with suburbs, 200,000 inhabitants. On the opposite side of the river is the British Residency, the stream being here bridged by nine spacious arches of squared granite. Besides these erections, and the palace of the native sovereigns, we may mention the principal mosque which has been fashioned after the model of the Kaaba at Meccah; while at the meeting of the four principal streets of the city rises another remarkable edifice, with four minarets resting on four connected arches, on which run the four converging thoroughfares. The neighbourhood abounds with huge tanks. One of them, close to the British cantonment of Secunderabad, measures three miles by two; and another, still larger, is said to be twenty miles round.

**HYDERABAD,** the chief city of Sind, stands four miles to the east of the left bank of the Indus, in lat. 25° 22′ N. and long. 68° 28′ E. Pop. about 24,000. The place is famous for the manufacture of arms of various kinds, such as matchlocks, swords, spears, and shields. As against a native force, it is tolerably strong, occupying a somewhat steep height, and having a rampart flanked by round towers.

**HYDNUM,** a genus of fungi (Hymenomycetes), having the undersides of the julius covered with soft spines which bear the spores. The species are pretty numerous, some of them British; among which is *H. repandum,* more common in some parts of the continent of Europe, and much resembling a sailors in France, Italy, and Germany. It grows on the ground, chiefly in pine and oak woods, either solitary, or in clusters or rings.

**HYDRA,—The, or Fresh-water Polyse, is the type of the class Hydrozoa, which, with the Anthozoa, from the sub-kingdom Cenote-rata of recent zoologists.**

See Zoophytes.

The H. possesses a gelatinous, sub-cylindrical body, which, from its contractility, undergoes various alterations of form. One end expands into a disc or foot, which adheres to a leaf, twigs, &c.; while a mouth, surrounded by the tentacles, varying from five to twelve or more in number, is situated at the opposite end. These tentacles are exceedingly contractile, at one moment thrown out as long delicate threads, at the next, drawn up into minute wart-like knobs. Numerous thread-cells project from their surface, the larger ones possessing a sheath and three recurved darts or barbs, and terminating in a long and extremely slender filament. The mouth leads into a capacious cavity, excavated throughout the whole length of the animal, which, exclusive of its tentacles, seldom exceeds three-fourths of an inch. On minutely examining the H., or any member of the class Hydrozoa, the body is found to be composed of two membranes, an ectoderm and an endoderm, the former constituting the outer layer of the animal, and having one side always in contact with the water, while the other side is in close contact with the endoderm, whose free surface forms the lining of the great internal cavity. The food of the H. consists of such minute living organisms as come within the reach of its tentacles, and by these apparently fragile threads, which the animal projects like a lasso, crustaceans, worms, &c., are seized, which

---

**Hydra:**

would be deemed at first sight superior to their captor in strength and activity. The tentacles appear, however, to possess, through the action of the thread-cells, a powerful benumbing or paralyzing influence, for it has been observed that soft-bodied animals which have succeeded in escaping from the grasp of the H. frequently die very shortly. The prey, when mastered, but often when still alive, is thrust into the internal cavity, which is nutritive and protective to the H., while the indigestible portions are expelled through the mouth.

Although the H. is usually found adhering by its circular foot or disc to submerged leaves, twigs, etc., it is not uncommon to find them on the body of the parent animal, which, as they increase in size, gradually resemble it: becoming perforated at their free extremity, and tentacles gradually being formed. The pellicle by which they originate by degrees become thin, and finally disappear, leaving the H. perfectly independent. One of the most remarkable points in the history of this animal is its power of being multiplied by mechanical division. If a H. be cut into two, or even more pieces, every one will, in time, assume the form and functions of the original animal.

Several species of H., such as H. viridis, H. pulchra, H. fusca, etc., have been described, which differ in size, colour, etc. When living hydres are removed from the water they often like minute specks of jelly, which quickly recover their true form on being restored to their proper element. The great authority on these singular animals is Trembley, whose Memoire pour servir a l'histoire d'un corps de petits animaux, a son d'heures was published in 1744.

HYDRA, a fabulous monster of the ancient world, said to have inhabited the marshes of Lerna, in Argolis, not far from the sea-coast. Accounts vary both as to its origin and appearance. Some make it the issue of Styx and the Titan Pallas, and others, of Echidna and Typhon. It is represented as having several heads, which immediately grew up again as often as they were cut off. The number generally ranged from seven to nine, though Simonds gives it fifty, and certain historians a hundred, and even more. Its mouths, which were as numerous as its heads, discharged a subtle and deadly venom. The destruction of this reptile was one of the twelve labours of Hercules (q.v.).

HYDRA, an island of Greece, is situated off the eastern shore of the Peloponnese (now the Morea), about 5 miles distant from the coast of the department of Argolis and Corinth. It is about 13 miles long, and 3 miles broad, and has an area of 38 square miles. The shores are rocky and steep, and the interior, rising to about 1800 feet in height, is destitute of vegetation and of water. On the north-west coast are the ruins of Hydra, the white, flat-roofed houses of which, ascending from the harbour, climb up the side of a hill. The streets, owing to the irregularity of the site, are steep and unplaned, but remarkable. This town, the only town on the island, is one of the most beautiful in the whole of Greece. Pop. 12,000, who are chiefly employed in cotton and silk weaving, in tanning, and in commerce.

The island of H. was uninhabited in ancient times. The nucleus of the town was formed by a few fishermen and peasants, who, suffering from the oppression of the Turks, crossed over from the neighbouring mainland, and were afterwards followed by others who had established themselves in the island. In 15th and 16th centuries. In the Grecian war of independence, the Hydriotes took a most active part; and none were more liberal in their contributions to the patriots. In 1828, the population was estimated at 40,000, and about three-fifths of the islanders were considered the richest in the archipelago. They possessed exclusively the carrying-trade of the Black Sea and the Mediterranean, and traded to England, the Baltic, and even America. Since the revolution, however, more accessible ports have risen to be the centres of Greek commerce, and H. has considerably declined.

HYDRA CIDS, or HYDROGEN ACIDS, a name given to acids in which the acidifying principle was supposed to be hydrogen. See Acids. The term acids into oxoacids and hydroacids belongs rather to a past than to the present state of chemistry.

HYDRA GOGUES are those active purges which produce a great flux from the intestinal membrane, and which consequently give rise to very watery stools. They are of extreme use in some of the varieties of dropping being the most proper for the purposes of diminishing the liquid poured into the cellular tissue and serous cavities of the body. Jalap (especially when combined with bitartrate of potash) and elaterium, a medicine which, from its extreme power, must be given in very small doses (one-eighth to one-third of a grain), and with great caution, are perhaps the best examples of this class of purges.

HYDRA NIGEA, a genus of plants of the natural order Hydrogammae, which many botanists make a sub-order of Saxifragae, distinguished by having 4–6 petals, 8–12 or many stamens, a more or less inferior ovary, and 2–5 styles. Hydrogammae are shrubs with opposite, or sometimes whorled leaves, destitute of stipules. In the genus H. the flowers are in cymes, the external flowers sterile and dilated. Few species are known, and they are chiefly native of the southern parts of North America, and of China and Japan. The species properly known as the Hydrangea (H. hortensis), is a native of China and Japan, and has long been in cultivation there as an ornamental plant. It was introduced into Britain by Sir Joseph Banks in 1758, and speedily became popular, being readily propagated from layers and cuttings, so as to be not only a favourite greenhouse plant, but a frequent ornament of cottage windows. In the south of England, it endures the open air. It seems almost impossible to water it too freely; a large plant has been known to receive with advantage one hundred gallons of water daily; and in favourable circumstances, it becomes a magnificent shrub. A plant in flowerowering has had 1000 large cymes of flowers expanded at once. The flowers, generally pink, are sometimes blue; the blue colour is owing to peculiarities of soil. Peat and iron ore are said to be productive of blue flowers in the Hydrangea—H. japonica introduced into Europe from Japan by Sobold, is remarkable for its very large cymes of flowers.—H. nivea and H. quercifolia, American species, are not unfrequently to be seen in floriculturists in North America.

HYDRAULICS are cleanances in which a definite quantity of water is chemically combined with a definite quantity of some other constituent. Although water is a perfectly indifferent substance, possessing neither acid nor basic properties, yet it enters into combination both with acids and with
HYDRAULIC LIMES AND MORTARS—HYDRIDE.

bases, and thus forms the bodies termed hydrates. Thus, when an acid has once been allowed to combine with water, the entire separation of the water can usually only be effected by the presence of some strong base, which displaces the water. For example, when we distil dilute sulphuric acid, water is expelled up to a certain point, when both acid and water are distilled together. The liquid now contains one equivalent of water, and one of acid \((\text{H}_2\text{SO}_4)\), and is termed hydrated sulphuric acid, and this equivalent of water can only be displaced by an equivalent of potash, or some other base. Water which thus supplies the place of a base in combination with acids is termed basic water. Hydrate of baryta \((\text{BaO}_2\text{H}_2\text{O})\), hydrate of linite or slaked lime \((\text{CaO}_2\text{H}_2\text{O})\), and hydrate of oxide of iron \((\text{Fe}_2\text{O}_3\cdot3\text{H}_2\text{O})\), and hydrate of oxide of copper \((\text{CuO}_2\text{H}_2\text{O})\), are similar cases, except that here the water is displaced by an acid instead of a base. The above are examples of hydrates of acids and bases or oxides. Gypsum \((\text{CaSO}_4\cdot2\text{H}_2\text{O})\) is an example of a hydrate of a salt.

HYDRAULIC LIMES AND MORTARS. See CEMENTS.

HYDRAULIC PRESS, called also Bramah's Press, from the name of its inventor, depends on the principle, that a pressure exerted on any part of the surface of a liquid is transmitted undiminished to all parts of the mass, and in all directions. See HYDROSTATICS. The annexed figure represents the essential parts of the machine, the details of construction being omitted. \(F\) is the cavity of a strong metal cylinder \(E\), into which the piston \(D\), passes without tightness through the top. A tube, \(G\), leads from the cylinder to a force-pump \(H\); and by means of this, water is driven from the tank \(T\) into the cavity \(F\), so as to force the piston, \(D\), upwards. The piston supports a table on which are placed the bales, books, or other articles to be pressed; and the rising of the table presses against the entablature \(AA\), which is fastened to the pillars \(B\), \(B\). The power of the press is readily calculated. Suppose that the pump has only one-thousandth of the area of \(F\), and that, by means of its lever-handle, the piston of the pump is pressed down with a force of 500 pounds, the piston of the barrel will rise with a force of one thousand times 500 pounds, or more than 200 tons. The rise, however, will be slow in proportion to the power. The enormous multiplying power given by this machine has been employed for a great variety of useful purposes, such as compressing bales of cotton, paper, tobacco, wool, &c., for expressing oil from seeds, and raising weights. This was the means employed for launching the Great Eastern at Millwall, and for raising to their position the tubes of the Britannia Bridge.

HYDRAULIC RAM, a simple and conveniently applied mechanism, by which the momentum or weight of falling water can be made available for raising a portion of itself to a considerable height. In the annexed figure, which represents a section of Montgoulry's hydraulic ram, \(R\) is the reservoir from which the water falls, \(RS\) the height of the fall, and \(ST\) the horizontal tube which conducts the water to the engine \(ABHTC\). \(E\) and \(D\) are two valves, the former of which closes its cavity by ascending the latter by descending; and \(FG\) is a pipe reaching within a very little of the bottom \(CR\). The valves are such that the water at its normal pressure cannot support their weight; the valve \(E\) is prevented from falling below a certain point by a stop below \(ms\). When the water is allowed to descend from the reservoir, after filling the tube \(BHS\), it rushes out at the aperture \(ms\), till its velocity in descending \(RST\) becomes so great as to force up the valve \(E\), and close the means of escape. The water being thus suddenly checked, and unable to find a passage at \(ms\), will produce a great action on every part of the containing vessels, and by its impact raise the valve \(D\). A portion of water being admitted into the vessel \(ABC\), the impulse of the column of fluid is expended, the valve \(D\) and \(E\) fall; the opening at \(D\) being thus closed, and that at \(ms\) opened. The water now rushes out at \(ms\) as before, till its motion is again stopped by its carrying up the valve \(E\), when the operation is repeated, the fluid impulse opening the valve at \(D\), through which a portion of the water passes into \(ABC\). The valves at \(E\) and \(D\) thus alternately closing and opening, and water at every opening of \(D\) making its way into \(ABC\), the air therein is condensed, for it has no communication with the atmosphere after the water is higher than the bottom of the pipe \(FG\). This condensed air, then, exercises great force on the surface, \(op\), of the water, and raises it in the tube, \(FG\), to a height proportioned to the elasticity of the imprisoned air. The principles of the hydraulic ram are susceptible of a very extensive application. In well-constructed rams, the mechanical effect obtained should be from 65 to 75 per cent. of the force supplied. For raising comparatively small quantities of water, such as for single houses, farmyards, &c., the ram is the best mechanism yet introduced. But the concussion, and consequent deterioration of the valves, places a limit to the use of the mechanism when applied to raise large quantities.

HYDRIDE-E, a family of serpents, sometimes so defined as to include numerous fresh-water snakes which are not venomous, and sometimes limited to venomous sea-serpents, inhabiting the Indian.

Banded Sea Snake (Chelydra Fasciata) : 
\[ \text{a, head; b, part of back.} \]
HYDRODES—HYDROCEPHALUS.

Chinese, and tropical Australian seas. These sea-serpents, forming the genus Hydrophus (or Histrurus), and other genera recently separated from it, have the tail compressed and the body keeled, so that they have the power of swimming like eels; they have small heads and small eyes; they are remarkable for the large size of their nasal shields; they are generally of a yellowish-green colour, varied with blackish rings or lozenge-shaped spots. Their lungs are often prolonged into a reservoir of air as far as the commencement of the tail. They are often from two to five feet long. They are frequently seen asleep on the surface of the sea, and are easily caught in this condition, in which, apparently, they often fall a prey to sharks. They are supposed to live on small fishes and crustacea. They are sometimes found coiled up among seaweed on the shore, and are much dreaded by fishermen. In some places, they are very numerous. One species, at least, is esteemed good food by the Tahitians. More than fifty species are known.

HYDRIDES. This term is applied both to combinations of hydrogen with metals, and to similar compounds of the oxygen and compound radicals. Hydrogen forms hydrides with at least four metals—viz., arsenic, antimony, copper, and potassium. The first two of these are the well-known gases, arsenic hydride (AsH₃) and antimoniretted hydride (SbH₃). The hydrides of methyl or marsh-gas (C₃H₈), and the hydride of ethyl (C₂H₅H₂), are examples of the second variety of hydrides.

HYDROCARBONS. See CARBONHYDROGENS.

HYDROCELE (Gr. hydor, water, and kele, a swelling) is the medical term for a dropsey of the tunics vaginae and serous membranes of the sac investing the testis. Hydrocele occurs as a smooth, pear-shaped swelling, fluctuating when pressed, devoid of pain or tenderness, but sometimes causing a slight uneasiness from its weight.

The quantity of serous fluid in the sac is usually from six to twenty ounces, but it occasionally exceeds a hundred ounces. Hydrocele may occur as a result of acute inflammation, but it most commonly comes on without any apparent local cause. It is most frequently met with about or beyond the middle period of life, and generally in persons of feeble power, or with a tendency to gout; sometimes, however, it occurs in young children. In the same form, as in adults, it is known as what is termed congenital hydrocele, when the communication between the tunica vaginalis and the abdominal peritoneum is not obliterated, as it normally should be.

The treatment is divided into the palliative and the curative. By the former, the surgeon relieves the present annoyance of his patient, while by the latter he aims at the permanent removal of the disease. The palliative treatment consists in the use of suspensory bandages, evaporating and disinfectant lotions, and tapping with a fine trochar. Tapping seldom gives more than temporary relief, the swelling usually again regaining its former bulk in two or three months.

The curative treatment consists in setting up sufficient inflammation in the tunica vaginalis to destroy its undue secreting faculty. This is most commonly done by the injection of tincture of iodine into the cavity thus formed, the needle being passed through the scrotum, or an iron wire (as proposed by Dr. Simpson) through it.

HYDROCEPHALUS. Under this term, which literally means water in the head, are included three distinct diseases—viz., acute hydrocephalus, chronic hydrocephalus, and spurious hydrocephalus, or, as Dr. Simpson terms it, hydrocephalus minimus, or hydrocele idiotica.

By Acute Hydrocephalus is signified inflammation of the brain as it usually occurs in scrofulous children. The name is not a good one, because it merely refers to a frequent effect of the disease, and not to its cause or essence; and because, further, a similar effect may result from other morbid conditions: it is, however, so universally adopted, that it would be inexpedient to change it. The disease is not so dangerous a nature, that it is of the greatest importance to detect the earliest stage, and even to look out for indications of its approach. The premonitory symptoms (which, however, do not occur in all cases) consist chiefly in a morbid state of the nutritive functions. The appetite is capricious, the tongue foul, the breath offensive, the belly enlarged, and sometimes tender, and the evacuations unnatural; and the child is heavy, languid, and dejected, and becomes either restless and irritable, or drowsy and listless. Restless sleep, attended by grinding of the teeth or moaning, a frequent sudden shriek, clenching of the fists, and a turning in of the thumb towards the palm of the hand, are also important premonitory warnings.

After these symptoms have lasted for some days, severe pain in the head comes on; it is generally of a sharp shooting character, recurring at intervals, and often during sleep, and causing the child to shriek in a very characteristic manner. Coma or morbid drowsiness is now supervened, and the shrieking is replaced by moaning. Vomiting is a frequent concomitant of this stage of the disease. In this first stage of hydrocephalus, which most commonly lasts two or three days, the pulse is rapid, and the symptoms generally are those of excitement. In the second stage, the pulse becomes irregular, variable, and often slow. General heaviness and stupor come on. The light, which annoyed the child in the first stage, is now relieved, or it is replaced by a feeling of complete emptiness; and all the symptoms of excitement cease. Sometimes the child falls into a deep sleep, in which the heart action is the only indication of life; and when one of these attacks lasts a day or two, it is generally superseded by a deeper stupor than before. The symptoms in the third or last stage, which may last only a few hours, or may extend to a fortnight, or even to a month, are those in the second stage, the pulse again becomes very rapid, beating sometimes so quickly that it can scarcely be counted, and gradually gets more and more weak, till the patient expires. The characteristic appearances after death are softening of the central part of the brain, with the effusion of serous fluid, usually to the extent of several ounces, into the ventricles; and a tubercular deposit, in the shape of small granules, upon or between the membranes of the brain.

The only disorder with which acute hydrocephalus can easily be confounded is infantile remittent fever; but we have not space to notice the various points which enable us to discriminate between these two complaints. Acute hydrocephalus is not a disease of childhood; it scarcely ever occurs after the twelfth year. Half the cases that occur are in children between three and six years of age. As a child should be left entirely to the physician, it is unnecessary to notice it further, than to state that strong antiphlogistic remedies—such as cold to the head, leeching, and active purging—applied in the first stage of the disease, yield the most satisfactory results; yet under this treatment, three cases out of four are lost.
HYDROCHLORIDE—HYDROCHLORIC ACID.

Chronic Hydrocephalus is a perfectly distinct disease from acute hydrocephalus; while the latter is an inflammation, the former is a dropping. In chronic hydrocephalus, a watery fluid collects within the skull, before the bones have united to form the solid brain-case, and by pressure outwards causes the bones to separate, and increases the size of the head sometimes to an enormous extent. Thus Dr. David Monro relates the case of a girl six years old whose head measured two feet four inches in circumference. While the skull is rapidly enlarging, the bones of the face grow no faster than usual, and the great disproportion of size between the head and the face is at once diagnostic of the disease. This disorder sometimes commences before birth, and almost always in early childhood, before the fontanelles and sutures of the skull are closed. In rare cases, it has occurred later, as, for example, at seven or nine years old, and the closed sutures have opened under the augmenting pressure. When the sutures will not yields, death from pressure on the brain speedily ensues. More frequently hydrocephalus either recover or die in infancy, but a few survive, bearing their complaint to adult life, or even to old age. Blindness, deafness, palpus, and idocy— one or more—are commonly associated with this disease, but occasionally the intellect and senses are sufficiently perfect for the ordinary requirements of social life.

The treatment may be attempted by internal remedies or by surgical appliances. The medical treatment consists in the administration of diuretics, purgatives, and especially mercury, which may be given in the form of calomel in minute doses, and applied as ointment externally, and also in the shape of calomel and puncturing the head. The former has in some cases effected a permanent cure; the latter has in many cases certainly prolonged life, although the disease has finally conquered. Neither of these means is applicable after the bones of the skull have united.

This disease occasionally occurs in adult or in advanced life, after enlargement of the head has become inconsiderable. Stupor, paralysis, and an inability or unwillingness to speak, are in these cases most prominent symptoms. Death from this disease was due to this disease, and it is recorded that during the last three years of his life he remained in a state of silence, with few and slight exceptions.

Spurious Hydrocephalus—Dr. Marshall Hall—resembles acute hydrocephalus in many of its symptoms, and has often been mistaken for it. Instead, however, of being an inflammatory disease, it is a disease of debility, and is due to a deficient supply of blood to the brain. The following are, according to Watson, the distinctive characters of this spurious hydrocephalus: the pale, cool cheek; the half-shut, regardless eye; the incoherent parlour; the interrupted, sighing respiration; and the state of the unclosed fontanelle. If the symptoms are those of acute hydrocephalus, the surface of the fontanelle will be convex and prominent; while if they are due to spurious hydrocephalus, and originate in emptiness and atrophy, the fontanelle will be concave and depressed. The remedies in this disease, which readily yields to treatment, are nourishing diet, small doses of wine or even of brandy in arrow-root, desecion of bark, ammonia, &c.

HYDROCHLORIDE, or HYDROCHLORIC ACID. See Anacardium and Vallisneria.

HYDROCHLORIC ACID (symbol, HCl; equivalent, 1 equivalent of water, no white salt of baryta should be produced by the addition of chloride of baryta.)

The presence of hydrochloric acid, or of the 289 and chlorine) be mixed in equal volumes, they will remain without action upon each other, if kept in the dark; but as soon as they are brought into direct sunlight, they unite with a loud explosion, and hydrochloric acid gas is the result. The principal characters of this gas are, that it is colourless, intensely acid, and inflammable, and it is even when largely diluted, is very irritating to the lungs and eyes, and very injurious to vegetation; that it is heavier than air (its specific gravity being 1.2474, air being taken at 1000); that it can be condensed into a colourless liquid; that it is very soluble in water, and that it is neither combustible nor a supporter of combustion. When allowed to escape into the air, it produces white fumes, by condensing the atmospheric moisture. If the air be previously dry, no such fumes are produced.

The solutions of this gas in water form the acid which was first known as Spirit of Salt, then as Muriatic Acid, and which is now termed Hydrochloric or Chlorhydric Acid. A saturated water at 40° F has a specific gravity of 1.21, and consists of 1 equivalent of the gas dissolved in 6 equivalents of water. It forms a colourless, fuming liquid, which acts as a caustic. On heating, the gas is evolved abundantly until the temperature is not slightly above the boiling point, distills over a dilute solution, having a specific gravity of 1.1, and consisting of 1 equivalent of the gas, and 16 equivalents of water. It is to these solutions of hydrochloric acid that the term hydrochloric acid is most commonly applied. It is a liquid gas itself. They possess the ordinary characters of an energetic acid, and neutralise the strongest bases. The neutralisation is, however, not in consequence of the acid combining with the oxide, but is due to the simultaneous decomposition of the acid and of the oxide, water and a metallic chloride being formed. If M represents the metal, the reaction is expressed by the equation M + HCl = MCl + H2O. All metals which, at a red heat, decompose water, also decompose this acid, and cause an evolution of hydrogen, the reaction being expressed as follows: M + HCl = MCl + H2. Hydrochloric acid gas is a common gaseous volcanic product. Free hydrochloric acid, in a very dilute form, is also a constituent of the gastric juice of man and animals, and plays an essential part in the digestive process.

Commercial or Muriatic acid—to use the name employed by manufacturing chemists—is made by heating, in iron cylinders, common salt (chloride of sodium) and oil of vitriol (hydrated sulphuric acid), and condensing the evolved gas in water contained in a series of stoneware Wolfe's Bottles (q. v.), the reaction being explained by the equation:

\[
\text{Chloride of Sodium + Oil of Vitriol + Hydrochloric Acid} \rightarrow \text{Salt of Sulphur + Sulphuric Acid}
\]

\[
\text{ClNa} + \text{HOSO}_2 = \text{HCl} + \text{Na}_2\text{SO}_4
\]

This commercial acid may contain various impurities—as, for example, iron (which gives it a bright deep yellow colour), the chlorides of sodium and arsenic—the latter being derived from the oil of vitriol—sulphur and sulphurous acids, chlorine, &c.; from which it is usually kept free by gentle distillation or redistillation. If pure, says Professor Miller, 'the acid should leave no residue when evaporatated; on saturating it with ammonia, it should give no precipitate of oxide of iron; sulphurated hydrogen should produce no turbidity in it, which would be the case if arsenic, free chlorine, or sulphurous acid were present; and on dilution with three or four times its bulk of water, the white salt of baryta should be produced by the addition of chloride of baryta.
HYDROCYANIC ACID.

The addition of a few drops of a solution of nitrate of silver, which occasions the formation of a white curdy precipitate of chloride of silver, is employed in the determination of a brown substance known as paracynogen. Pure hydrocyanic acid may be kept unchanged if excluded from light, which occasions its decomposition, and the formation of a brown substance known as paracynogen.

Hydrocyanic acid is readily obtained by distillation from the kernels of bitter almonds, and many kinds of seeds, fruits, from the leaves and flowers of various plants, and from the juice of the tapoca plant (Jatropha manihot). Anhydrous hydrocyanic acid is obtained by the reaction of concentrated hydrochloric acid on cyanide of mercury.

The ordinary tests for hydrocyanic acid are the following:

1. The peculiar odour; 2. The nitrate of silver test: the addition of a few drops of a solution of chloride of silver forms a white precipitate of cyanide of silver, which is soluble in boiling nitric acid; 3. The formation of Prussian blue, by adding to the fluid under examination a solution of some proto- and per-salt of iron, by saturating with caustic potash, and finally adding an excess of hydrochloric acid; when, if hydrocyanic acid is present, we have a characteristic blue precipitate; 4. The sulphur test, which is the best and most accurate that has yet been discovered. Let the suspected liquid be acidulated with a few drops of hydrochloric acid; place it in a watch-glass, and let a second watch-glass, moistened with a drop of a solution of hydro-sulphate of ammonia, be inverted over it; after a few minutes, let the upper glass be removed, and the moistened spot be gently dried. The whitish film which is left may consist merely of sulphur; when hydrocyanic acid is present, it consists of sulphocyanate of ammonia.

2. ITs Medicinal Uses.—We are indebted to the Italians for the introduction of hydrocyanic acid in the materia medica; and it was first employed at the beginning of the present century. There are no cases in which it is so serviceable as in those affections of the stomach in which pain is a leading symptom, as in gastrolysis, water-brash, and in cases of intense vomiting. Hence it is often useful in English cholera, when opium has completely failed. In pulmonary diseases, it does not produce the good effects that were formerly ascribed to it; but it is sometimes useful in allaying spasmotic cough. It has been employed with advantage in chronic skin-diseases, to allay pain and irritation. It is the drachm of the dilute acid (of 2 per cent. strength) with half a pint of rose-water, and half an ounce of rectified spirit, forms a good lotion. When given internally, the average dose is from 3 to 5 minims of the 2 per cent. dilute acid, three or four times a day; it must be administered in some milk vehicle, such as simple water, or orange-flower water.

3. As A Poison.—Hydrocyanic acid is one of our
most energetic poisons, and is frequently employed both in murder and suicide. When a small poisonous dose (about half a drachm of the 2 per cent. acid) has been taken, the first symptoms are, weight and pain in the head, with confusion of thought, giddiness, nausea (and sometimes vomiting), a quick pulse, and loss of muscular power. If death result, this is preceded by tetanic spasms and involuntary evacuations. When a large dose has been taken (as from an ounce to an ounce of the 2 per cent. acid), the symptoms may commence instantaneously, and it is seldom that their appearance is delayed beyond one or two minutes. 'When,' says Dr. A. S. Taylor, 'the patient has been seen at this period, he should be used with great caution, and only by the medical practitioner. Cold affusion on the head, neck, and down the spine is a valuable remedy, and it is asserted that its efficacy is almost certain when it is employed before the convulsive stage of poisoning is over, and that it is sometimes successful even in the stages of insensibility and paralysis. Artificial respiration (see Respiration, Artificial) should never be omitted. Dr. Pereira states, that he once revived a rabbit by this means only, after the convulsions had ceased, and the animal was apparently dead.

HYDRODYNAMICS treats of the laws of the motion of liquids; the flow of water from orifices and in pipes, canals, and rivers; its oscillations or waves; and its resistance to bodies moving through it. The term hydraulics is sometimes applied to the same subjects, from the Greek word αὑδρος, a pipe. The application of water as a moving power forms the practical part of the subject. In what instance, the illustrations are mostly taken from the case of water, but the principles established are true of liquids in general.

Effect.—If three orifices, D, C, E, are made at different heights in the side of a vessel (fig. 1), filled with water, the liquid will pour out with greater impetuosity from C than from D, and from E than from C. The velocity does not increase in the simple ratio of the depth. The exact law of descent (that of Torricelli; the demonstration is too abstruse for introduction here, but the law itself is as follows: 'Particles of fluid, on issuing from an aperture, possess the same degree of velocity as if they had fallen freely, in vacuo, from a height equal to the distance of the surface of the fluid above the centre of the aperture.' The jet from C, for instance, has the same velocity as if the particles composing it had fallen freely in vacuo from the level of the liquid to C. Now, the velocity acquired by a body in falling is as the time of the fall; but the space fallen through as the square of the time, it follows that the velocity acquired is as the square root of the space fallen through. In the first second, a body falls 16 feet, and acquires a velocity of 32 feet. If E, then, is 16 feet below the level, a jet from E, flows at the rate of 32 feet, and if D is at a depth of 4 feet, the velocity of the jet at D will be half the velocity of that at E, or 16 feet. In general, to find the velocity for any given height, multiply the height by 2 x 32, and extract the square root of the product. This rule may be expressed by the formula

\[ v = \sqrt{2gh}, \]

where \( v \) signifies the velocity of the issue, \( g \) the velocity given by gravity in a second, or 32 feet, and \( h \) the height of the water in the reservoir above the orifice. This last quantity is technically called the head or charge.

That this theory of the efflux of liquids is correct, may be proved by experiment. Let the vessel, MB (fig. 1), have an orifice situated at \( o \); the water ought to issue with the velocity that a body would acquire in falling from \( M \) to the level of \( o \). Now, it is established in the doctrine of Projectiles (q. v.), that when a body is projected vertically upwards with a certain velocity, it ascends to the same height from which it would require to fall in order to acquire that velocity. If the theory, then, is correct, the jet ought to rise to the level of the water in the vessel at \( M \). It is found in reality to fall short of this; but not more than can be accounted for by friction, the resistance of the air, and the water that rests on the top in endeavouring to descend. When the jet receives a very slight inclination, so that the returning water falls down by the side of the ascending, ten inches of head of water may be made to give a jet of nine inches. A stream of water spouting out horizontally, or in any oblique direction, obeys the laws of projectiles, and moves in a parabola; and the range of the jet for any given velocity and angle of direction may be calculated precisely as in projectiles. The range of horizontal jets is readily determined by practical geometry. On AB describe a semicircle; from \( D \), the orifice of the jet, draw DF perpendicular to AB, and make DH equal to \( D'F \). But this can be proved by the laws of falling bodies and the properties of the circle, that the jet must meet BL in the point K. If BE is equal to AD, the perpendicular EH is equal to D'F; and therefore a jet from \( E \) will have the same range as that from \( D \). Of all the perpendiculars, CG, drawn from the middle point \( C \), is the greatest; therefore, the jet from \( C \) has the longest possible range.

The area of the orifice and the velocity of the flow being known, it is easy to calculate the quantity of water discharged in a given time. Thus, suppose the area to be 1 square inch, and the velocity 20
HYDRODYNAMICS.
a seccMd, it is evident that there issues in a
HOOod a cylinder or a prism of water 1 square inch
jn section and 20 feet long, the content of which is
In any given time,
1 X 240 = 240 cubic inches.
then, as three minutes (=.180 seconds), the discharge is 240 x 180 = 43.200 cubic inches.
It has as yet been assumed that the water in the
vessel or reservoir is kept constantly at the same

only the central part of the jet, which approaches
the opening directly, that has the velocity above
stated.
The outer particles approach from all
sides, with less velocity; they jostle one another,
as it were, and thus the flow is retarded.
In consequence of this want of uniformity in velocity and
direction among the component layers of the jet,
as they enter the orifice, there takes place what is
called a contraction of the vein (rena contracta)
that is, the jet, after leaving the orifice, tapers, and
becomes narrower. The greatest contraction is at
a distance from the orifice equal to half its diameter;

than in the side on a level with the bottom.
the discharge-tube is made to project inwaidi
the thickness of the walls of the vessel, the
velocity is much imjieded, owing to the opposing
currents produced by the water approaching the
opening.
Pi/ma—When a conduit pipe is of any cotaiderable length, the water issues from it at a velocity
less than that due to the head of water in tha
reservoir, owing to the resistance of friction. With'
a pipe, for instance, of 1} inch in diameter, and 90
foet long, the discharge is only one half what it
would be from a simple orifice of the same diameter.
The rate of reduction de]>ends ujion the diameter
of the tube, its length, the bendings it undergoes
&c The resistance to the flow of water in pipe*
does not arise projwrly from friction, as understood
of solids, but from the adhesion of the water to
the sides of the pipe, and from the cohesion of the
vessel,

leet

;

i

watery particles among themselves ; it makes little
difference, therefore, whether an earthenware pipe,
for instance, be glazed or not.
Large projections
form an obstacle ; but mere roughness of surface
is filled up by an adhering film of water, which is
as good as a glaze.
The resistance increases greatly
with the narrowness of the pij»es. Engineers have
formulas, deduced iu great part from experiment,
for calculating the discharge through pqies of given
length and diameter, and with a given head; hat
the subject is too complicated for introduction here.
If water flowed in a conduit pipe without friction
or other obstruction, so that its velocity were
always equal to that due to the head of waWr,
there would Iks no lateral or bursting pressure oa
the walls of the pipe ; and if the pipe were pierced,
the water would not squirt out Accordingly, with
a short tube or adjutage, which, instead of ol*tructing, increases the flow, there is not only no lateral
outward pressure on the walls of the tube, but there
is actually a pressure inwards.
If a hole is made
(tig. 2), and
in the wall of a cylindrical adjutage,

A

Adjutage*.—It has as yet been supposed
the issue is by means of a simple opening or
in the side or bottom of the vessel ; but if the
takes place through a short tube, the rate of

that
hole
flow
dis-

charge is remarkably affected.
Through a simple
opening, in a thin plate, the actual discharge is only
about 64 per cent, of the theoretical ; through a
cylindrical conducting-tube, or adjutage, as it is
called, of like diameter, and whose length is four
times its diameter, the discharge is 84 per cent.
The effect iB still greater if the discharge- tube is
made conical both ways, first contracting like the
contracted vein, and then widening. The effect of
a conducting-tube in increasing the discharge is
accounted for by the adhesion of the water to its
sides, which widens out the column to a greater
area than it would naturally have. It has thus a
tendency to form a vacuum in the tube, which acts
like suction on the water in the reservoir, and
increases the quantity dischan^d.
The flow is
mote free if the orifice is in the bottom of the

HYDRO-FLUORIC ACID.—HYDROGEN.

It is greatly affected by the shape of the body, which ought to have all its surfaces oblique to the direction of the motion. When a cylinder terminates in front in a hemisphere, the resistance is only one-half what it is when the cylinder terminates in a plane surface at right angles to the axis; and if instead of a hemisphere, the termination is an equilateral cone, the resistance is only one-third. If, however, the resistance of a cylinder, whose length and the diameter of whose base are each equal to the diameter of the globe, is fixed between them; this cylinder with hemispherical ends experiences less resistance than the globe alone, the diminution being about one-fifth of the resistance to the globe. Also the resistance increases in a higher ratio than the simple one of the velocity. One part of the resistance arises from the momentum that the body has to give to the water it displaces. Moving at a certain rate, it displaces a certain quantity; moving at twice that rate, it displaces twice the quantity in the same time. But not only does it displace twice the number of particles of water; it also has, by consequence, twice the velocity; the pressure of the resistance is thus not merely doubled, but quadrupled or squared. Similarly, when the velocity is tripled, the resistance is nine times as much. If the place of one of the wheels becomes nine times as great. Another part of the resistance of liquids to bodies moving in them is owing to the cohesion of the particles, which have not to be thrown aside merely as separate grains, but to be turned around. In this, when the velocity is considerable, the water becomes heaped up in front, and depressed at the other end from not having time to close in behind, thus causing an excess of hydrostatic pressure against the body. The most important part of it is the cohesion of the water, the pressure of the cohesion of the water being 0.0692; hence hydrogen is 141 times lighter than atmospheric air; while, on the other hand, it is 241.573 times lighter than platinum, the heaviest body known. Its refractive power is greater than that of any other gas, and is more than 6 times as great as that of atmospheric air. It is combustible; that is to say, it is capable of combining with oxygen, and developing light and heat. When a lighted taper is passed up into an inverted jar of hydrogen, the gas burns quietly with a pale-blue, scarcely visible flame, and the taper is extinguished. The flame only occurs at the line of junction of the hydrogen and the surrounding air. If the hydrogen be mixed with water or oxygen prior to the application of the taper, the whole mixture is simultaneously inflamed, and there is a loud explosion, which is the most violent when 2 volumes of hydrogen are mixed with 1 volume of oxygen, or with 3 volumes of atmospheric air. The hydrogen and oxygen in these cases combine to form watery vapour or steam, which suddenly expands from the high temperature attendant on the combustion, but immediately afterwards becomes condensed; this condensation causes a partial vacuum, into which the surrounding air rushes, and by the collision of its particles, produces the report. At ordinary temperatures, water dissolves rather less than 2 in 100,000 of its volume of hydrogen. It is an emulsion of the few gases which has never yet been liquefied. Pure hydrogen, though it cannot support life, is not poisonous, and when mixed with a sufficient quantity of atmospheric air or oxygen, may be breathed for some time without discomfort.

Hydrogen does not possess very marked chemical properties. The only substances with which it combines directly at ordinary temperatures are chlorine and oxygen. Hydrogen and chlorine, united together, and exposed to direct sunlight, combine with explosion; in diffused daylight, they gradually unite; but in the dark do not act on one another. Hydrogen and oxygen do not combine spontaneously even in direct sunlight, but require the presence of a red-hot solid, of flame, or of spongious platinum.

It is generally stated that hydrogen does not exist naturally in a pure or uncombined state, but Bunsen recognised its presence in variable proportions in the gases evolved from the sulfatasas of Iceland, and it will probably be detected in other localities where similar geological relations hold good. In combination with oxygen, as water, it not only forms a very considerable part of the atmosphere, and of the bodies, but is a constituent essential ingredient of the water, it enters largely into the composition of every animal and vegetable organism. It is an essential ingredient of many inflammable minerals, such as coal, amber, and petroleum; and of certain gases, such as marsh gas, ammonia, and hydrogen sulphuric acid (or sulphurated hydrogen). It likewise enters into the composition of a large number of manufactured substances and products used in the arts, medicine, &c., as for instance, sal-ammoniac, tar, sugar, starch, alum, oil, tannin, indigo, morphia, strychnia, hydrocyanic acid, &c.

There are numerous ways in which hydrogen may be prepared, but the usual and most convenient process is by the action of diluted sulphuric acid on zinc. About half an ounce of granulated zinc is placed in a retort, and a dilute acid, prepared by gradually mixing an ounce of oil of vitriol with six ounces of cold water, is poured on the zinc. Hydrogen gas is rapidly evolved in great abundance, but the first portions should not be collected, since they are mixed with the atmospheric air which was contained in the retort. The rest of the gas may be collected in the ordinary way over water. In this process the gas takes the form of a yellow oxide of zinc, which combines with the sulphuric acid, forming sulphate of zinc, which remains in solution, while the hydrogen of the decomposed water escapes. The reaction is shown in the formula, $\text{Zn} + \text{HO}_2\text{SO}_4 = \text{ZnSO}_4 + \text{H}_2$. A precisely similar reaction ensues if we use iron in place of zinc, but in this case the gas is generally less pure.

Hydrogen gas, under the name of combustible air, was obtained in the 17th c. by Paracelsus by treating certain metals with dilute acids, and was more or less known to Boyle and others; but Cavendish, in his paper on 'Frictional Airs,' published in the Transactions of the Royal Society for 1766, was the first to discern accurately the properties of this gas, and the methods of obtaining it; hence he is usually mentioned as its discoverer.

HYDROGEN, Binoxide of (symbol H$_2$, equiv. 1), is a colourless liquid of a syrupy consistence, having a specific gravity of 1.456, a summer's odour, and a peculiar odour, something like that of very dilute chlorine. It bleaches vegetable colours, and when applied to the tongue or the skin, produces a white spot, and excites considerable pain. From its readiness with which it gives off its hydrogen, it is a powerful oxidising agent. The method of
HYDROGRAPHY—HYDROPATHY.

preparing it is complicated and difficult. This substance was discovered in 1823 by Dr. W. B. Richardson, an eminent London physician, has lately examined its value (in solution) as a therapeutic agent, and has found it to be of extreme use in hooping-cough, in certain forms of rheumatism, and as (a palliative) in the last stages of consumption.

HYDROGRAPHY (Gr. hukol, water, graph-, to write) is a description of the surface waters of the earth, particularly of the bearings of coasts, of currents, soundings, islands, shoals, &c., and of anything the knowledge of which may be useful for purposes of navigation. It, consequently, includes the construction of charts, maps, &c., in which these particulars are detailed. It is, in fact, to the sea what geography is to the land. The first step in the creation of hydrography into a science, was made in the 15th c. by Henry the Navigator, who was the first to construct a sea-chart worthy of the name. Among the maritime nations of Europe, it is now made a matter of prime concern; the hydrography, in certain branches of the naval administration. The head of the hydrographic department in the British service is usually a captain in the royal navy. The officers surveying in different parts of the world send for observations, soundings, &c., and it is the business of the hydrographer to consolidate these into available maps. The hydrographer receives £300 a year in addition to his half-pay. In proof of the value attached to these Admiralty charts among the marines of England, and even of foreign nations, it may be mentioned that in 1859, no less than 68,270 charts, besides 6918 books of sailing directions, were sold.

HYDROMANCY. See Divination.

HYDROMANIA. See Pellagra and Suicide.

HYDROMETER. See Arizometer.

HYDROMYS, a genus of rodents quadrupeds, of the family Muridae, of which there are only two known species, very similar to one another, natives of Van Diemen's Land. They have two incisors and four molars in each jaw. They are called BEAVER RATS in Van Diemen's Land; are nocturnal and very shy; inhabit the banks both of fresh and salt water, and swim well. The largest species is twice the size of a common rat. One of them has the belly white, the other yellow.

HYDROPATHY, or HYGIENIC MEDICINE, popularly termed the WATER CURE. Under the head of Baths and Bathing (q. v.) an account has been given of the bath in general, as a means of preserving health. We have here to speak of water in its manifold uses as an engine in the cure of disease, and as forming a principal element in that combination of hygienic appliances which goes to make up hydrotherapy as at present practised. (In accordance with the plan followed in other cases of the kind, the view exhibited is that of an adherent of the system.)

The efficacy of water, in the cure of numerous forms of disease, has long been recognised. Water was largely employed by Hippocrates, the 'Father of Medicine,' more than 2300 years ago, in the treatment of many kinds of disease; and along with a regulated diet, and an implicit belief in the cures of nature, it appears to have formed the chief element in his medical armoury. Horace has enshrined the memory of Antonius Musa, the hydropathic physician of the Emperor Augustus (Epist. I. 15). Both Coels and Ainus, by works flourished, the two centuries n. c., and the other in the 2d c.—speak favourably in their writings of the use of water in the cure of disease, regarding it as of high value in the treatment of acute complaints, particularly those of the stomach. Throughout the Middle Ages, likewise, many physicians of name, including Aetius and Paulus Aegens, and the more celebrated Paracelsus, were advocates of the remedial virtues of water; all of them, however, having, as is usual, used water in treatment rather empirically than from theoretical knowledge.

In 1723, Nicolo Lanzani, a Neapolitan physician, published a learned treatise on the subject. In our own country, about the beginning of the 18th c., Sir John Floyer and Dr. Baynard made a large use of water. Their compound work, denominated Psychrolustia, or the 'History of Cold Bathing, both Ancient and Modern,' is replete with quaint learning and practical shrewdness and sagacity. But the most able and scientific of all the older treatises that have appeared in England on the subject of the water treatment, is the work of the well-known Dr Currie (q. v.), the biographer of the poet BURNS, published in 1797, and entitled Medical Reports on the Effects of Water, Cold and Warm, &c. In this work, Dr Currie recommends the cold affusion in typhus and other fevers, and gives practical directions in regard to the cases and the times when it may be used with advantage. He also says that the physicians of the last century had admitted that these views, so far as they went, were as scientific in principle as they were novel in their application; but the practice founded on them was considered too dangerous by Currie, and its advocates are now in fact generally neglected. It is worthy of remark, that Currie appears to have limited his use of water to acute ailments exclusively.

We have thus seen that up to the beginning of the present century, hydromathy, by some of the physicians, who employed it as a curative agent, water was used in the treatment of acute, and by others of chronic diseases; by some as an internal agent alone, by others as an external application in the various forms of the bath, and even as a simple remedy, and little or no specialty neglect. It is worthy of remark, that Currie appears to have limited his use of water to acute ailments exclusively.

HYDROPATHY.

'Water-cure,' a name scientifically one-sided and incomplete, and therefore misleading. It is equally to be regretted that many of the immediate followers of Priestley, as well as of his contemporaries of sagacity and genius, should have been no better furnished than himself with a scientific knowledge of disease and general professional culture.

In spite of all drawbacks, however, the unbounded confidence in its success was confessed by many men of standing in the profession, who, allowing for some of its early extravagances, stepped forth to explain it scientifically, and pressed it on the acceptance of their brethren; and from their advocacy has sprung up in England a school of hydopathetic physicians, the philosophy of whose plan of treatment we shall now briefly describe.

Physiology teaches us, that the various organs of our bodies cannot be kept in a healthy state without the observance of certain regulations called the primary 'Laws of Health.' When these are broken, the result to the offender is disease in one of its many forms. Until the appearance of hydropathy, physicians attempted to correct the evil thus caused— and the great majority do so still—by the administration of one or other of the drugs which go to form the medical repertory known as the pharmacopoeia. A statement on which this practice has been based is that very ancient one, that experience has proved the medicine or medicines to be efficacious in a large proportion of similar cases. Hydropathy proceeds according to a very different method. The first, and central matter, is the simple first propounded by Hippocrates, that it is nature's own strivings after health (via medicatrix nature) that really cure the patient when he is cured, the function of art being mainly to remove obstacles, the natural physician avoids using all means with whose effects he is not thoroughly conversant, or which may, at least, interfere with nature's own operations. Hence, as a rule, he eschews the use of drugs, and betakes himself to those more simple natural agents which, in their totality, receive the name of hygiene. The conditions of health, as unfolded by physiology, may be briefly stated to consist of five necessary requirements—air, exercise, water, diet, and nervous repose. These are essentially essential to the preservation of health; no human being can possibly continue in a fair state of health when deprived of the just proportion of any one of them. This proposition, which may be regarded as a principle of hygiene, was announced by Priestley, and is the basis of hydopathic medicine in the cure of disease. Admitted that certain agencies are necessary to the preservation of health, the hydropathic principle is simply this, that the very same agencies, infinitely modified of course according to the requirements of each particular case, and generally much intensified, are not only the safest, but by far the surest means of curing chronic disease; or, to put it more correctly, are the best means which can be brought to nature's assistance for enabling her to effect a cure herself.

Here it is proper to explain what is meant by saying that the natural agents of health are intensified when they are used, not for the preservation of health, but the cure of disease; or, in other words, when we pass from natural hygienics to natural therapeutics. Take the element of exercise, for instance, one of the most powerful hydopathetic agents. Every one knows how much benefit is derived systematically on the knowledge, that a certain amount of exercise is necessary to maintain the body in health; the hydropathic doctrine, accordingly, is, that in the cure of chronic disease, this exercise must not be entirely withdrawn, but to what extent the patient's strength will warrant. So, again, as to the use of water: a certain amount of pure water, used externally and internally, is also necessary to the maintenance of health; hydropathically, a much more liberal use of the same element in both ways is necessary to the cure of disease. The reader's special attention is called to this, which in fact is the very kernel of the hydropathic theory.

Let us now explain more in detail how and in what cases hydropathy employs the agencies on which it relies. Diseases may, for general purposes, be divided into two great classes: those in which the physician is called on to lower or reduce to the standard of health; and those in which the object of his endeavours is, on the other hand, to assist in elevating to the same standard. In the former category, range themselves all those diseases which are marked by a plethoric or inflammatory type—by an overplus of mal-directed strength in the economy; in the latter, those distinguished by a corresponding diminution in the vital powers. It may be truly affirmed, that to rectify both these abnormalities, and to restore the equilibrium of health, is the great object of medical treatment. The ordinary practice seeks to achieve this object mainly, in both instances, by means of drugs, respectively adapted to the two classes, and tending to lower in the one case, or to raise in the other. The hydropathic practice, with the same object in view, employs, as already stated, the natural remedies—air, exercise, water, diet, and repose.

Thus, in dealing with acute and plethoric complaints, and the whole order of diseases putting themselves under the former of the divisions just indicated, water is the element which enacts by far the most conspicuous part, and the application of it most serviceable in these cases is the wet sheet or pack. Indeed, the discovery by Priestley of this application of water was perhaps the most important contribution which he made to the new system of which he was the practical founder, inasmuch as it at once supplied one of the most powerful and at the same time one of the safest methods of combating almost every form of acute disease. This, the most distinctive of hydropathic appliances, may be thus described: Over the mattress of a bed or sofa is extended a stout blanket, and on this is spread a linen sheet, well wrung out of cold water, so that it is only damp. On this the patient is laid, and immediately enveloped tightly with a heavy weight of blankets and linens in so close a manner as to exclude all air. The body's natural heat, acting on the damp linen, generates vapour almost immediately, and the patient forthwith finds himself, not in a cold, but in a comfortably warm vapour bath—in a novel, but by no means unpleasant form of body poltice. The effects of this process on the economy seem to be plain enough. It is clear, in the first place, that the pores of the skin, so numerous and performing so important a function, must thereby be thoroughly cleansed, and the blood itself depurated; with the equalisation of temperature over the entire surface of the body, will follow a corresponding equalisation in the distribution of blood throughout the system, thereby relieving internal congestions wherever occurring; and lastly, from the soothing effects on the nervous system, and the allaying of all irritation, must result not only the alleviation of pain, but that lowering of the heart's action, and with it of the circulation of the blood, of such incalculable importance in the treatment of many forms of disease, and especially of fevers. Such is the wet sheet.

Of the same class, though in many respects very different from it, is the Turkish bath, recently introduced into England, and now fairly...
HYDROPATHY.

established throughout the country. In this bath, the hydropathic procedure has received a most important auxiliary in the treatment of many forms of disease, but in an especial manner of the kind more particularly under consideration at present, such as gout, rheumatism, bronchitis, and other complaints of an inflammatory or febrile character. This has not been a matter of standing, or being, is secured, although not so efficiently, by means of the vapour bath as used by the Russians, and by hot air as generated by the spirit-lamp. The latter has the advantage of being less expensive, and the bath not being required to breathe the heated air, many persons can use it who would be quite unable to require, without faintness, the highly heated atmosphere of the Turkish bath. In addition to the above, must be mentioned the use of warm fomentations, in the form of flannels wrung out of boiling-water—a kind of application much relied on for subduing local pain proceeding from whatever cause, for relieving congestion, and abating and checking inflammation. So much for the principal hydropathic operations employed to treat acute and inflammatory diseases—processes corresponding in their aims and effects to antiphlogistic, diaphoretic, and sedative drugs.

We have now to speak of the hydropathic agents brought to bear on the second great division of maladies, wherein the object is not to lower, but to elevate, to the standard of health. In the former class of cases, it was stated that the agent most prominently brought forward, and it is in such diseases alone that the term 'water cure' is at all appropriate. In those we are at present dealing with, water certainly plays an important part, but not in its combination with good air, exercise, regulated diet, and nervous repose, that diseases are cured as they are. As an illustration: A cold bath is given in the usual way as a tonic. Its effects are admirable under certain conditions—the first and best of these being that of a severeegovision takes place; that the blood, which had been driven by the constricting effects of the cold water from the surface of the body into the inner parts, should return in increased force when the stimulus of cold is withdrawn. But to this end, in all but very strong persons, exercise immediately after the bath is indispensably necessary, and must follow it as a matter of course, or the bath cannot be administered with any form with safety. It may be said for the co-operative importance of pure air, of diet, and of nervous repose, all of them, if necessary to the preservation of health, of tenfold importance in the cure of disease. Thus the highly tonic properties of the bath, administered in its various forms, and followed by a due proportion of exercise, more especially in strong bracing air, produce at once a marvellous effect in sharpening the appetite and improving the powers of digestion, so that, if simple and nourishing diet is administered, better blood will be elaborated, and, consequently, every tissue of the body be more highly nourished and invigorated. It is scarcely necessary to say, that, in all cases, this and must always be a gradual process, for it is evident that the treatment pursued, whether in reference to exercise, diet, or the use of the stimulus of water, must bear an accurate relation to the invalid's strength. Little by little, how much in most cases than might be imagined, improvement begins to take place. From the great action brought to bear on the skin by means of the different applications of water, the most useful of all the hypocausts, of Turkish bath, and the effects of full exercise, a rapid change of the particles of the body takes place—so rapid, that, according to Liebig, by means of the water-cure-treatment, a change of matter is effected in a greater degree in six weeks, than would happen in the ordinary course of nature in three years. While at the same time, the effect matter thrown off is replaced by the healthier materials supplied to the economy by an improved quality of blood, itself the result of an improved digestion, and this, again, reinforced and assisted by the beneficial effects of the combined hydropathic agencies have produced. The forms of the bath may of course be varied ed infinitum, as well as its power according to the temperature of the water. The baths most in vogue in daily practice are technically denominated the Wash down, Dripping sheet, Shallows, Sitz bath, and Douche, together with the Pack, or Wet sheet before mentioned; in addition to which there is a catalogue of local applications, too extensive to enumerate. These various appariances of water are capable of producing extraordinary effects on the economy, constituting, as they do, especially when conjointed with exercise, the most powerful tonics, and, at the same time, the most safe and agreeable, that can be brought to bear on the body. It might truly be added that, in the treatment of chronic disease, this same element, water, is capable of becoming, according to the manner and quantity of its use, instrumental to a perfectly internal, an alterative, a diuretic, and a diaphoretic. It is as a tonic and stimulant, however, that its virtues are most conspicuous, and most called into requisition for the cure of chronic diseases.

From a variety of circumstances, the system of hydropathic medicine has been greatly misunderstood and misjudged by the general public. For one thing, the name of 'water cure,' or 'hydropathy,' adopted by Pritz Reputation, has been very prejudicial, leading to the false inference that the one element of water alone constitutes the bone and marrow of the system, playing the part of a panacea for every form of human aiment. Such a notion has never been maintained by the practitioners of scientific hydropathy, and it is matter of regret that some more comprehensive and catholic title, as that of 'hygienic medicine,' has not long since been adopted. As it is, the prejudice against the system is gradually giving way; it is no longer treated as heresy by the orthodox profession; and many enlightened practitioners are in the habit of sending certain classes of their patients to hydropathic establishments, which are much mightily in the treatment. In fact, the tendency of ordinary medical practice has of late years been towards the principles on which hydropathy is based. A manifest disposition exists on the part of the most enlightened members of the profession to rely less on art and much more on nature in the treatment of diseases of every type, but especially those of a chronic character, than was formerly the case; and as the practitioners of scientific hydropathy by no means exclude the use of drugs, when they appear to be necessary, it would seem that a convergence of opinion is really coming about.

Hydropathy, hitherto, has been almost exclusively practiced in large establishments, prepared over by competent medical men, and dedicated to a thorough and systematic carrying out of the principles on which the system of cure is founded. There can be no question that this is by far the most complete and satisfactory mode of treatment. It can be superiorly and speedily accomplished. But the power of leaving their daily work for the purpose of seeking health, is what falls to the lot of very few; and if the hydropathic treatment of the bath, can be secured retreats in the country, and incompatible with the business and work of town-life, it would be shown of half its utility as a remedy, and be a luxury to
HYDROPHOBIA—HYDROPHYLLACE.

which only the rich and disengaged could aspire. But exercise, morning and evening, can usually be had by most persons. The same applies to the systematic and persistent use of the bath, to the regulation of diet, and to the disinclinations. By these means, even without country air and other hygienic adjuncts, no doubt a vast deal might be done both for the cure of disease and the preservation of health. Towards effecting the latter object, at least, one will deny the immense value of hydrotherapy. No one, having any practical acquaintance with it, can doubt its influence in the promotion of those habits of temperance, cleanliness, self-denial, and general obedience to the laws of health, which, when well kept, add much to the happiness of the individual, go no less to secure the strength and prosperity of nations. To those who would inquire further into the subject, we may recommend the work of Dr Gully, entitled The Water-cure in Chronic Diseases; that of Dr James Wilson, called Principles and Practice of the Water-cure; the several works of Dr Edward Johnson; and Dr Lane's treatise, Hydropathy, or Hygienic Medicine.

HYDROPHOBIA (derived from ψύξis, water, and φόβος, fear) is one of the several diseases produced by animal poisons. A person is bitten by a mad dog or other animal. The wound gradually heals in the ordinary manner. After an uncertain interval, usually ranging from six weeks to eighteen months, which is termed the period of incubation, the following symptoms appear: The patient experiences discomfort or pain at the seat of the bite. The cica trio tinges, or feels stiff or numb; sometimes the whole limb becomes swollen, and occasionally reappears, and discharges a peculiar ichor. The morbid sensations gradually extend from the original seat of injury towards the trunk. This period is termed the stage of recrudescence. Within a few hours, or, at longest, a few days after the exhibition of this local irritation, during which time the patient has a sense of general discomfort and illness, the specific constitutional symptoms begin to manifest themselves; he complains of pain and stiffness about the neck and throat, finds himself unable to swallow fluids, and every attempt to do so—often even the sight or the sound of fluids—brings on a terrible paroxysm of choking and sobbing; and this continues for two or three days, till the patient diuresis, or purges. The body is covered with a rash; the wind across the face, or the waving of a mirror before the eyes, is often sufficient to excite these paroxysms. The mental condition in the last stage of this disease varies: the patient may be calm and tranquil; generally he is irritable and apprehensive, and suspicious; and in most cases, a certain degree of delirium, or even mania, is associated with the irritability. Death most commonly takes place on the second or third day after the commencement of the specific symptoms.

Some medical writers have maintained that hydrophobia may occasionally be spontaneously developed in man, as is undoubtedly the case occasionally in the lower animals (see example); but even if this ever occurs, the instances are so extremely rare as not to affect the general statement, that in man the disease is the result of an animal poison, which is most commonly communicated in case of a mad dog, by means of the teeth, which have been produced by the bite of the wolf, the jackal, the raccoon, and the cat. The poisonous saliva is perfectly innocuous when applied to the unbroken skin; to produce its effects, there must be some abrasion of the cuticle; but according to the late Dr Youatt, it may enter the system by mere contact with mucous membranes.

The disease is said to have been caused by the mere scratch of a cat; but as both cats and dogs frequently apply their paws to their mouths, the poisonous saliva may be introduced in this way by the claws.

There has been much discussion as to what becomes of the poison. Is it immediately taken into the system generally, or does it remain imprisoned in the wound or cicatrix for a time? In the latter case, we might successfully remove it with the poison and the bitten part; and the period of recrudescence; and that the poison is thus locally retained seems more than probable from the fact, that at this period morbid phenomena of various kinds exhibit themselves at the seat of the wound, and that these phenomena are speedily followed by the characteristic symptoms of the disease.

Little need be said of the treatment of hydrophobia, for there is no well-authenticated case of recovery on record. The most distressing symptoms may, however, be alleviated by chloroform, opiates, the hot-air bath, &c. But although the disease cannot be cured, its development may be prevented by the early and complete excision of the bitten part, provided the situation of the bite allows of the free use of the knife. 'If,' says Dr Watson, 'the injury be so deep or extensive, or so situated that you cannot remove the whole surface of the wound, cut away what you can; then cleanse it thoroughly and for some hours together, by means of a stream of warm water, which may be poured from a tea-kettle; place an exhausted cupping glass from time to time over the exposed wound; and finally apply to every point of it a portion of lunar caustic. If you cannot bring the solid caustic into contact with every part, you had better make use of some liquid escharitic; strong nitric acid, for example.' Early excision is the only sure preventive, but if, for any reason, the operation has been omitted in the first instance, it is advisable for the reasons already given regarding the probable latency of the poison, to cut out the wound at any period before symptoms of recrudescence appear. The reason why many neglect to have immediate recourse to excision probably is, that hydrophobia by no means follows, as a matter of certainty, the bite of a rabid animal. John Hunter states that he knew an instance in which, of twenty-one persons bitten by a mad dog, one alone was infected. On the other hand, we have evidence that of one hundred and fourteen persons who were bitten by rabid wolves, sixty-seven, or more than one-half, were victims to this disease. Although we have no very trustworthy evidence on a large scale, there is no doubt that the majority of persons who are bitten by a mad dog do escape the disease, even without taking any precaution. In many of these cases, the virus is probably removed by the teeth passing through the clothes.

The nature of the disease in the dog or other animal whose bite causes hydrophobia, is considered under Rabies.

HYDROPHYLLACE., a natural order of exogenous plants, containing about 80 known species, natives chiefly of the colder parts of America. None of them are of importance for any use to which they have been applied, although Draymouth Canadaeflos has been used in North America a remedy for snake bites, and the leaves of H. Virgineum, or Shawanse Salal, are eaten by the Indians, both raw and boiled; but some of them are favourite ornaments of our flower-borders, particularly different species of Nenaphila. The order includes some small trees and bushes as well as herbaceous plants. They are often hispid, like the Boraginaceae.
HYDROSTATICS.

HYDROSTATICS treats of the equilibrium of liquids, and of their pressures on the walls of vessels containing them; the science depends on the way in which the molecules of a liquid form a mass under the action of gravity and molecular attraction, the latter of which is so modified in liquids as to give them their state of liquidity. While the particles of a liquid cohere, they are free to slide upon one another without appreciable friction; and it is this perfect mobility that gives them the mechanical properties considered in hydrostatics.

The fundamental property may be thus stated: When a pressure is exerted on any part of the surface of a liquid, that pressure is transmitted undiminished to all parts of the mass, and in all directions. Most of the other propositions of hydrostatics are only different forms or direct consequences of this truth. This is a physical axiom, but its truth may be experimentally proved.

Suppose a close box B filled with water, and having a tube a inserted into the upper cover, of an inch in area, and with a plug or pin a inserted into it. If the piston a is now pressed down upon the water with a force equal to a pound weight, the water, being unable to escape, will react upon the piston with the same force; but it obviously will not press more against a than against any other part of the box, therefore every square inch of the interior surface of the box is pressed outward with the force of a pound. If, then, there is another tube inserted in the box with a plug of the same area, as at b, it will require a force of a pound to keep this plug in its place. (We leave out of account the pressure upon b arising from the weight of the water in the box above it, and consider only the pressure propagated by the forcing down of the plug a.) However many plugs of the same size there were, each would be pressed out with the same force of a pound; and if there were a large plug of four times the area, as at c, it would be pressed out with a force of four pounds. We have only, then, to enlarge the area of the piston c to obtain any multiplication of the force exerted at a.

If the area of c is 1000 inches, that of a being one inch, a pressure of one pound on a becomes a pressure of 1000 pounds on c; and if we make the pressure on a one ton, that on c will be 1000 tons.

This seemingly wonderful multiplication of power has received the name of the hydrostatic paradox. It is, however, nothing more than what takes place in the lever, when one pound on the long arm is made to balance 100 pounds on the short arm.

If the pressure we have supposed exerted on the piston a arose from a pound of water poured into the tube above it, it would continue the same though the piston were removed. The pound of water in the tube is then pressing with its whole weight upon every square inch of the inner surface of the box—downwards, sideways, and upwards. The apparatus called the hydrostatic balance acts in the same manner (see fig. 2). It consists of two stout circular boards connected together by leather in the manner of a bellows, B. The tube A is connected with the interior; and a person standing on the upper board, and hanging at the end of a rope, will rise and fall. If the area of the upper board is 1000 times that of the tube, an ounce of water in the tube will support 1000 ounces at W. It is on the same principle that the Hydraulic Press (q.v.) depends.

After this explanation of the fundamental properties of liquids, it may be enough to state the two conditions of fluid equilibrium which directly flow from it.

(1.) Every molecule of the liquid must be subjected to equal and contrary pressures in every direction.

This is a corollary from liquid mobility.

(2.) The upper molecules of a liquid, which are free, must form a surface perpendicular to the impressed force.

The truth of this will sufficiently appear from the proof, that the surface of a liquid at rest under gravity must be what is called horizontal. It can be shown to be a consequence of the primary property of the liquid, "that it is equally impressed in all directions." For let dA and dB be vertical lines, or lines in the direction of gravity; and AB a plane at right angles to them, then, if AB is a pressure on the liquid at A, there would be a flow of the water from A towards B. It follows that the line ad is equal to bc, and hence that dc is parallel to ab, and therefore horizontal. The same might be proved of any two points in the surface; therefore the whole is in the same horizontal plane.

2. Pressure of Liquids on Surfaces.—The general proposition on this point may be stated thus: The pressure of a liquid on any surface immersed in it, is equal to the weight of a column of the liquid whose base is the surface pressed on, and whose height is the perpendicular depth of the centre of gravity of the surface below the surface of the liquid. See article CENTRE of PRESSURE. The pressure thus exerted is independent of the shape or size of the vessel containing the liquid.

3. Buoyancy and Flotation.—As a consequence of the proposition regarding the pressure of liquids on surfaces, it can be shown that when a solid body is immersed in a liquid, it loses as much weight as that of an equal bulk of the liquid weighs. It follows that, if a cubic foot of the liquid weighs more than one of the solid, the solid will not only lose all its weight, but will rise up, and that with a force equal to the difference; if a cubic foot of the liquid weighs less than one of the solid, the solid will lose weight, but will sink.

When a solid swims, or rises and floats on the surface of a liquid, the next problem of hydrostatics is to determine to what extent it will be below the surface. We have already seen that any solid in a liquid is pressed upward with a force equal to the weight of the water it displaces; on this principle. Now, a floating body must be pressed up with a
HYDROSTATICS—HYDROSULPHURIC ACID.

force equal to its own weight, otherwise it would sink lower; hence, a floating body displaces its own weight of the liquid. A solid, as AB in fig. 4, sinks until the space occupied by the part B immersed would contain an amount of water equal in weight to the whole solid AB.

As the buoyancy of a body thus depends on the relation between its weight and the weight of an equal bulk of the liquid on the same body will be more or less buoyant, according to the density of the liquid, in which it is immersed. A piece of wood that sinks a foot in water, will sink barely an inch in mercury. Mercury buoya up even iron. Also a body which would sink of itself, is buoyed up by attaching to it a lighter body; the bulk is thus increased without proportionally increasing the weight. This is the principle of life-preservers of all kinds. The heaviest substances may be made to float by shaping them so as to make them displace more than their own weight of water. A flat plate of iron sinks; the same plate, made concave like a cup or boat, floats. It may be noted that the buoyant property of liquids is independent of their depth or expense, if there be only enough to surround the object. A few pounds of water might be made to bear up a body of a ton weight; a ship floats as high in a small dock as in the ocean.

4. Stability of Floating Bodies.—Conceive abd (fig. 6) to be a portion of a liquid turned solid, but unchanged in bulk; it will evidently remain at rest, as if it were still liquid. Its weight may be represented by the force ec, acting on its centre of gravity; but that force is balanced by the upward pressure of the water on the different parts of the under surface; therefore, the resultant of all these elementary pressures must be a force, ec, exactly equal and opposite to ec, and acting on the same point c, for if it acted on any other point, the body would not be at rest. Now, whatever other body of the same size and shape we suppose substituted for the mass of solid water abd, the supporting pressure or buoyancy of the water around it must be the same; hence we conclude, that when a body is immersed in a liquid, the buoyant pressure is a force equal to the weight of the liquid displaced, and having its point of application in the centre of gravity of the space from which the liquid is displaced. This point may be called the centre of buoyancy.

We may suppose that the space abd is occupied by the immersed part of a floating body abcd (fig. 5).

The supporting force, eb, is still the same as in the former case, and acts at c, the centre of gravity of the displaced water; the weight of the body must also be the same; but its point of application is now c, the centre of gravity of the whole body. When the body is floating at rest or in a state of equilibrium, this point must evidently be in the same vertical line with c; for if the two forces were in the position of ec, eg (fig. 6), they would tend to make the body roll over. The line passing through the centre of gravity of a floating body and the centre of gravity of the displaced water, is called the axis of flotation.

The equilibrium of a floating body is said to be stable, when, on suffering a slight displacement, it tends to regain its original position. The conditions of stability will be understood from the accompanying figures. Fig. 7 represents a body floating in equilibrium, G being its centre of gravity, B its centre of buoyancy, and AGB the axis of flotation, which is of course vertical. In fig. 8 the same body is represented as pushed or drawn slightly from the perpendicular. The shape of the immersed portion being now a new one, the centre of buoyancy is no longer in the axis of figure, but to one side, as at B. Now, it is evident, that if the line of direction of the upward pressure—that is, a vertical line through B—is the axis above the centre of gravity, as at M, the tendency of the two forces is to bring the axis into its original position, and in that case, the equilibrium of the body is stable. But if BM meet the axis below G, the tendency is to bring the axis further and further from the vertical, until the body get into some new position of equilibrium. There is still another case; the line of support or buoyancy may meet the axis in G, and then the two forces counteract one another, and the body remains in any position in which it is put; this is called indifferent equilibrium. In a floating cylinder of wood, for instance, B is always right under G, in whatever way the cylinder is turned. When the angles through which a floating body is made to roll are small, the point M is not constant. It is called the metacentre; and its position may be calculated for a body of given weight and dimensions. In the construction and lading of ships, it is an object to have the centre of gravity as low as possible, in order that it may be always below the metacentre. With this view, heavy materials, in the shape of ballast, are placed in the bottom, and the heaviest portions of the cargo are stowed low in the hold. See Specific Gravity and Aреometer.

HYDROSULPHURIC ACID (HS), known also as Sulphurated Hydrogen, Sulphydric Acid, and Hydrobionomic Acid, is a natural gaseous constituent of many mineral waters, as, for example, those of Aix-la-Chapelle in Germany, Bareges in France, Abano in Italy, and Harrogate in England, and is evolved from fumaroles and volcanoes. It is formed spontaneously wherever sulphurous organic matters are undergoing putrefaction, as, for instance, in stagnant sewers and cess-pools, and in waters charged with vegetable, lye, and matter and sulphates, especially sulphate of lime.

There are several ways of preparing this gas, which is very extensively used in laboratory operations. The following is that which is most commonly employed. Sulphide (the old sulphur of iron, in small fragments, is placed in a bottle, and dilute sulphuric acid is added. Water is decomposed, its hydrogen combining with the sulphur of the sulphide to form hydrosulphuric acid, which
HYDROTHORAX—HYGROMETER.

escape as a gas, while its oxygen enters into combination with the iron, forming oxide of iron (FeO), which unites with the sulphuric acid to form the ordinary protosulphate of iron or green vitriol, which remains in solution. The expression is represented by the equation:

\[
\text{FeS} + \text{HO}_2\text{SO}_4 = \text{HS} + \text{Fe}_2\text{O}_3
\]

Hydrosulphuric acid is a colourless gas of a strong and very nauseous odour, resembling that of rotten eggs. It consists of two volumes of hydrogen and one volume of sulphur vapour condensed into two volumes, which form its combining measure. It is about seventeen times heavier than hydrogen. By pressure, it is liquefied, and by the additional application of cold, it may be obtained in a solid form by Thenard, who proved fatal—dissolves, at 59°, 3-23 volumes of this gas, but the solution soon becomes milky when exposed to the air, in consequence of the oxygen of the air combining with the hydrogen of the gas, and sulphur being converted into the highly combustible and serpentine state. When this solution is added to strong acids or alkalis, it burns with a pale blue flame, producing water and sulphurous acid, and, generally, a deposit of sulphur. It has a weak acid reaction, and forms one of the hydracids. Although a feeble acid, it combines with most bases.

Its use as a reagent is dependent on the fact, that many of the sulphides which it forms with metallic oxides are insoluble in water, and are thrown down from solutions as precipitates with characteristic colours. Thus the solution of it gives an orange precipitate with the compounds of antimony—which with those of arsenic it gives a yellow—and with those of lead and of silver, a black—and with those of zine, a white precipitate.

The use of a room slightly impregnated with this gas may be breathed with impunity, but a small quantity of the undiluted gas inspires faintness, and its respiration, in a very moderate proportion, is fatal. An experiment by Theophrastus, who proved fatal—birds perishing in air which contained \(\frac{1}{40}\)th, and a dog in air containing \(\frac{1}{400}\)th part of this gas. Its poisonous effects are best counteracted by the inhalation of very diluted chlorine gas, which may be readily obtained from a little chloride of lime placed in the folds of a napkin moistened with vinegar.

A very minute trace of this gas may be detected by placing a piece of paper moistened with a strong solution of sugar of lead, over the vessel or test-tube, and sealing it hermetically, for instance, over an opening in a drain—from which we think it is escaping. If it be present, a more or less black—often only a brown—tint is developed after a few minutes, in consequence of the formation of sulphide of lead.

HYDROTHORAX (derived from ὑδρός, water, and θόραξ, the chest) is the term applied to dropsical collections in the Pleura (q.v.), a closed sac, containing the lung on either side. When it exists to any extent, the pressure which it exerts on the lungs impedes the passage of the blood through them, and occasions difficulty of breathing, lividity of countenance, &c.; and more or less drop in the face, ankles, &c., soon appears. The physical signs by which the disease can be detected are too purely professional for these pages.

The causes of hydrothorax are various. It may depend upon inflammation of the secreting membrane, or it may be a consequence of organic disease of the heart or lungs. With regard to treatment when the disease seems to depend upon inflammation of the pleura, great advantage may often be derived from occasional cupping and repeated blistering. The most popular internal remedy is a combination of squill and either colonel or blue pill, which must be continued till slight symptoms of salivation manifest themselves.

HYDROZOA. See Zoophytes.

HYERES, or HIÈRES, a small town of France, in the department of Var, is situated three miles from the Mediterranean, and eight miles east of Toulon. It is celebrated for the beauty of the situation and the mildness of the climate, and is therefore much resorted to by foreigners suffering from chest or nervous complaints. Near the coast lie the Île d'Hères called by the ancients the Sterchades, which, with the exception of the military garrisons of a few forts, are uninhabited. Here, the heat of the climate is tempered by the sea-breezes, and the season seems an eternal spring.

HYGIÉA—in the classical myth, the child of Apollo and Health, the daughter of Asclepius. She was worshiped at Athens, Corinth, Argos, and other important cities, and works of art is usually represented as a blooming virgin, with a snake, the symbol of health, which drinks from an ear of wheat, or a hand, the symbol of hygiene. The word hygiene is the name of one of the newly-discovered Planetoids (q.v.).

HYGROMETER (Gr. ὑγρός, moist, μετρός, measure), an instrument for measuring the quantity of moisture in the atmosphere. The earlier forms of hygrometer depended upon the property possessed by some substances of readily absorbing moisture from the air, and being thereby changed in dimensions or in weight. Of this kind was the hair hygrometer of Saussure, in which a hair, which expands and contracts in length according as the air is more or less moist, was made to move an index; a similar instrument was the whalebone hygrometer of Dela; but as other causes as well as moisture affect the hair and other substances, they afford no accurate indications. The most perfect hygrometer, theoretically, is that of J. P. Daniell (q.v.). It consists of two bulbs connected by a bent tube, as represented in the figure, and enclosing a thermometer, together with the ether and vapour of ether, the air having been expelled. The bulb, b, is covered with muslin, and a is either the flask, or coated with metal. The observer's hand is placed for a short time on b, to drive the ether into a, leaving b and the tube filled with vapour of ether. A little ether is then dropped from a flask, of the form c, over the muslin-covered bulb; evaporation instantly takes place, and a cooling of b, which condenses the vapour inside; a fresh evaporation from a, the vacuum, which is again condensed by dropping ether on b, and the process is repeated till the temperature of a is so reduced by successive evaporations (see EVAPORATION), that it begins to be formed on the outside of the bulb. At
HAUSKOS—HYLROSAURUS.

The instant this occurs, the height of the mercury in the two thermometers is accurately noted, the one giving the dew-point temperature, and the other the temperature of the air. The actual quantity of moisture contained in a cubic foot of air can now be readily found from the following empirical formula: weight of moisture in grains = \[ 448 + \frac{t - 63}{2} \times \frac{h}{30} \]

where \( t \) is the temperature of the air at the time of observation, and \( p \) (found from tables) the elasticity of vapour at the temperature of the dew-point. The definition of degree of dryness of the instrument are, first, its rapidity of operation, so that no time is allowed for the glass, ether, and thermometer to come to the same temperature, and, in consequence, the dew-point is given higher than it actually is; secondly, its costliness, owing to the great consumption of ether; and, thirdly, its uselessness in tropical countries, owing to the difficulty of preserving the ether in a fluid state. Daniell's hygrometer was used at the Royal Observatory, Greenwich, from 1840— the commencement of meteorological observations— till 1847, when it was superseded by the more convenient instrument, the WET AND DRY BULB THERMOMETERS. This instrument consists of two thermometers—one of ordinary construction, which serves to give the temperature of the air; the other has its bulb covered with a piece of muslin or other similar material, to which is attached an absorbent wick, communicating with a vessel of rain-water, an arrangement by which the muslin is kept constantly wet. The evaporation from the muslin, and consequent cooling of the bulb, being in proportion to the dryness of the air, the difference between the readings of the two thermometers will be greatest when the air is driest, and zero when it is completely saturated with moisture. The height of the mercury in each of the thermometers being found, the elastic force of the vapour at the dew-point is calculated by the formula of Dr. Apjohn (Proceedings of the Royal Irish Acad., 1840):

\[ F = \frac{d}{88} \times \frac{h}{30} \]

\[ F = \frac{f - d}{96} \times \frac{h}{30} \]

The first formula to be used when the wet thermometer is above, and the second when it is below, the dry thermometer. In the former case, the elastic force of vapour at the dew-point; \( d \), the hygrometric depression, or depression of the dew-point; \( h \), the height of the barometer. After \( F \) has been determined, the quantity of moisture in a cubic foot of air can be found as before. (In these calculations, the Hygrometric Tables of Mr. Glashier will be found to be of great use.)

HYKSHOS, the name of an Egyptian dynasty, generally known as the Shepherd Kings, derived from ϫϩ, a ruler, and ϛϩ, a shepherd; or, according to another version, from ϫϩ, a captive, and ϛϩ, a shepherd. According to Josephus and Africanus, they consisted of six or eight kings, named (1) Salatis, Silitus, or Saites, who reigned 18 or 19 years; (2) Boon, Banon, or Bon, who reigned 43 or 44; (3) Apachnas, Apachan, or Pachnas, who reigned 36 or 61 years; (4) Aphopis, Aphoisis, who reigned 61; (5) Ana, or Anan, who reigned 36; (6) Archel, who reigned 49; (7) Anisa, or Asseth, who reigned 49 years and 2 months; and (8) Apothis, who reigned 61 years. The greatest discrepancy exists in the names and their arrangement, and as to the total number of years of the dynasty. Manetho, according to Josephus, states that they reigned 511 years; but the total of the reigns he cites amounts to only 259 years 10 months; while Africanus makes their duration 284 years, and Eusebius 163. Africanus makes the Shepherds consist of the 15th, 16th, and 17th dynasties, and have ruled 953 years, but only gives the names and reigns of one, which he calls the 15th; while Eusebius makes them more correctly the 17th dynasty. They are stated in the Egyptian annals to have been a race of conquerors among the Ethiops of the East, who, under Salatis, their first king, took Memphis, and rendered tributary the whole of Egypt, and fortified the city of Avaris, on the east of the Bubastite arm of the Nile, where he maintained a garrison of 240,000 soldiers. Their oppression, however, drove the Egyptians to revolt, and under Taakan, the predecessor of Ahmes or Amosis I., of the 18th dynasty, a religious quarrel about the temples of Ra or the sun, and of Set, the god of the H., seems to have commenced, when a long war broke out, which ended under Ahmes, with the siege of Avaris, and a king who is called Misphragmuthous, supposed to be a Thothmes, finally drove them out. The monument of an officer, named Ahmes-Pennelum, at Elkab, recounts this siege and his exploits. Finally, according to Manetho, they departed under treaty. The great interest attaching to the H. is, that they were confounded with the Hebrews, or supposed to be the monarchs under whom Joseph entered Egypt, and the old ecclesiastical writers. In the monuments and the papyrius of Turin, in which portions of their names occur in the list of the kings, they bear the full titles of monarchs, although the papyrius asserts that there were no kings in Egypt at the time, and that Taakan was only himself ahek, or prince of the south. The H., on a contemporary inscription remaining at Elkab, are called Men or Shepherds. The H. were by Josephus the devastating conquerors described by the historian. They entered Egypt, it appears from the monuments, about the 14th Egyptian dynasty, and were content with inscribing their names and titles on the monuments of their predecesors, the name of the H., however, is found on a colossal of Sebekhet III. of the 13th dynasty, and on that of a king of the 14th dynasty at San. Traces of that of Saites or Salatis have been also found at Tel-Mokdam or Cynopolis. The great divergence of opinion has prevailed amongst authors as to their race and origin. Josephus calls them Hebrews or Arabs; the Synecellus, Phoenician shepherds. They have also been supposed to be Idumans, the Babylonians, or Scythians, and the Tolomeians. The name of the H. seems to indicate a Semitic origin, while their worship of Set connects them with the Khita, a people to the north of Palestine, on the confines of Mesopotamia. The names of the kings exhibit no foreign peculiarities; some are purely Egyptian. As regards the date of the H. dominion, the most conflicting opinions have prevailed amongst scholars. Bunsen makes their rule end 1639 B.C.; Lepsius, 1842 A.D. Placing, however, the discovered date of Thothmes III., 1445 A.C., in his 16th year, the close of H. dominion must have ended about 1500 B.C.

HYLOSAURUS' (Gr. forest-lizard), a huge dinosaurian reptile, found in the Wealden strata of Kent and Sussex. Fragments of individuals have been found sufficient to give an approximate notion of the affinities and great size of this reptile. The bones of the head have not yet been observed; its teeth were comparatively small, and close set; they seem to indicate that it was a vegetable eater. The body was broader than high, and terminated in a long slender flexible tail; the limbs were relatively short; the skin was covered with scutes and tubercles; and a row of very large
HYMEN.—HYPERESTHESIA.

thin angular bony spines extended down the back, and formed a serrated dermal crest, like the horny spines of the modern iguana. It is supposed to have attained a length of 25 feet. The remains of only one species have been found; it has been named H. Owen.

HYMENÆUS, or HYMENÆUS, in Grecian mythology, the god of marriage; but originally, the word seems to have denoted only the bridal-song which was sung by the companions of the bride as she went from her father's house to that of the bridegroom. The name Hymen is mentioned by Sappho. The legends concerning him are various; but he is generally said to be a son of Apollo and some one of the Muses. He is represented as a boy with wings and a garland, a bigger and graver Cupid, with a bridal-torch and a veil in his hands.

HYMENOPTERA (Gr. membrane-winged), an order of insects, containing a very great number of species, estimated at about one-fourth of the whole class, and of which some, as ants and bees, are singularly interesting and important. They have the mouth furnished with mandibles for cutting and tearing, but the other parts of the mouth are adapted for suction, and are generally narrow and elongated, often united into a kind of proboscis, as in bees. See BEE. The antennæ are generally slender, but often exhibit differences in the sexes of the same species. The wings are four in number, in the first pair larger than the second, the wings of the same side united in flight by little hooks. The wings, when at rest, are laid one over

Wing of Honey Bee. another horizontally over the body. The wings are entirely membranous, not reticulated, as in the Neuroptera, but with comparatively few nervures, the arrangement of which is so constant in the whole order, that particular names have been given to them and to the spaces between them, and their diversities have been made use of in classification. The wings are wanting in the imperfectly developed females (neuters) of some. Besides the ordinary eyes, all the H. have three small simple (or stemmatoic) eyes on the top of the head. The abdomen is generally united to the thorax by a slender pedicle. The abdomen of the females is generally furnished with an organ capable of being protruded, but for different purposes in different sections of the order, it being in some of the hymenopterous tribes an ovipositor or bore, and in others a sting. The H. in their perfect state generally feed on honey, but some of them prey on other insects, which are the food of the larva of a greater number; while the larvae of some feed on various vegetable substances. The metamorphoses of the insects of this order are perfect; the larvae are generally—all though not in all the families—destitute of feet: the pupa take no food. The H. are remarkable for the dilatation of the tracheæ or air-tubes into vesicles, and the general perfection of the respiratory system. The instincts, and even apparent intelligence, displayed by some of them—particularly the social orders, which live in communities—have excited admiration from the earliest times. The order is divided into two sections—Terebrantia, having an ovipositor; and Acalypta, having a poison-reservoir and sting. To the former belong saw-flies, gall-flies, ichneumons, &c.; to the latter belong ants, bees, wasps, &c.

HYMETTUS, a mountain in Attica, now called Trelo Vouni, situated to the south-east of Athens, and famous among the ancients for its honey and its marble. The honey still retains its reputation.

HYMN. A canticle of praise or prayer addressed to the divine honour. The word in its strict acceptance supposes a certain metrical structure, or at least some kind of rhythmical cadence. The use of hymns dates from the earliest days of Christianity (Matt. xxvi. 30, Col. ii. 16); but our information as to the hymns of the early ages, and still more as to their authors, is extremely imperfect. The Te Deum is variously ascribed to St Ambrose, St Hilary, to Ambrose, and to Prudentius. The hymns of St Prudentius, with greater certainty, are assigned the Hymn of Holy Innocents, Saliere Flores Martyrum, and the Addi Diei Nuntius. Even the names of the authors of the more modern hymns are often involved in mystery; but some of the most esteemed hymns are known as the productions of S-Justinus, of Fortunatus, of Paul the Deacon, of St Bernard, and St Thomas. The number of hymn-writers in the modern languages is so great as to preclude the possibility of any enumeration. The most complete modern collection of medieval Latin hymns is More's Hymni Latini Medii Aevi, 3 vols. Sti. Friburg, 1856.

HYOSCYAMUS. See Henbane.

HYPATIA, daughter of Theon, an astronomer and a Neoplatonic philosopher. She was born in the Neo-Platonic school in that city, was born in the latter part of the 4th century. She was equally remarkable for her beauty, her wisdom, and her tragic fate. From her earliest youth, she exhibited an ardent love of study, and had as a consequence, for her father, one of the most erudite savans of his time, resolved to give her genus a thoroughly philosophic culture. She succeeded her father in the chair of philosophy at Alexandria; and the fame of her lectures drew round her students from all parts of the East where the influence of Greek thought and knowledge was felt. H. seems to have been worthy of the lofty eulogies she has received. Amid the widespread corruption of Alex- andria, she lived as spotless as a vestal; and if her teaching was not one that could lay a strong hand on the vices of heathenism, and arrest their course, it was at least sufficient not only to pre- serve youth from vice, but also to inspire her with a love of beauty, truth, and goodness, that was Christian in its spirit and earnestness, if heathen in its form and limitations. The citizens of Alex- andria were proud of her; and such reliance was placed on her judgment and opinion by the magistrates used frequently to consult her on important cases. Among those who were most intimate with her was Orestes, prefect of the city. At this time, the Bishop of Alexandria was Cyril (q. v.), a fierce hater of heathens and heretics. Defeating Orestes, whom he suspected of being no true Chris- tian, and who had drawn up an accusation against him for exciting a tumult, he soon cast an evil eye on H., whom he regarded as a Satanic enchantress, and the grand obstacle to his reconciliation with the prefect. His hatred communicated itself to the lower clergy, and especially to certain savage monks from the Nitrian deserts, who, headed by one Peter, a hermit, attacked H. in the streets, and then returning from her lecture-room. The maiden was dragged from her chariot, hurried to the Cæsarian Church, where she was stripped naked, and murdered with tiles, after which she was torn to pieces, and her limbs carried to a place called Cinaron, and there burned to ashes, 415 A.D.

HYPERASTHESIA (derived from hyper, over, and aesthesis, a sensation) include those affections which have this property in common—viz. as excited irritability and increased irritation of the
HYPERBOLA—HYPERTROPHY.

serves. Hyperesthesia of the cutaneous nerves is manifested by pain in its various modifications, which is sometimes intensely severe, as in Tic Douloureux (q. v.), while hyperesthesia of the nerves of special senses is manifested by phantasms, illusions, &c. The following points are common to the whole class of these affections: 1. Periodicity, or the alternations of paroxysms and intermissions; 2. Uniformity and persistence of the symptoms, however long the duration of the disease; 3. No danger to life; 4. Freedom from this class of diseases in early life. Of the diseases predisposing to hyperesthesia, hysteria is far the most frequent; but it is sometimes induced by rheumatism, gout, skin-diseases, &c.

HYPERBOLA. If two similar cones be placed apex to apex, and with the lines joining the apex and centre of base in each, in a straight line: then if a plane which does not pass through the apex be made to cut both cones, each of the two sections will be a hyperbola, as PBN, PAN'. It is, viewed analytically, the locus of the point to which the straight lines EP, FP differing by constant quantity are drawn from two given points E and F. These given points are called the foci, one being situated in each hyperbola. The point G, midway between the two foci, is called the centre, and the line EF the transverse axis of the hyperbola. A line through G perpendicular to the transverse axis is called the conjugate axis; and a circle described from centre B, with a radius equal to FG, will cut the conjugate axis in C and D. If G be taken for the origin of co-ordinates, and EM and EF for the axes, the hyperbola is expressed by the equation \( b^2 - a^2 = 1 \). (GB = a, GC = b). The hyperbola is the only conic section which has Asymptotes (q. v.); in the figure these are GT, GT'; GN, GS. It also appears that if the axes of co-ordinates be turned at right angles to their former position, two additional curves, ICK, IOK', will be formed, whose equation is \( b^2 - a^2 = 1 \). These two are called conjugate hyperbolas, and have the same asymptotes as the original hyperbola. These asymptotes have the following remarkable property: If (starting from G) the asymptotes be divided in continued proportion, and from the points of section lines be drawn parallel to the other asymptote, the areas contained by two adjacent parallels and the corresponding parts of the asymptote and curve are equal; also lines drawn from the centre to two adjacent points of section of the curve, enclose equal areas. The equation to the hyperbola when referred to the asymptotes is \( y = ab \); which shews that as the ordinates decrease in geometrical progression, the abscissce increase in the same ratio.

HYPERBOLÉ (Gr. hyper, over, and ballein, to throw) is the name given to a figure of rhetoric, by which expressions are employed that, taken literally, signify more than really is meant. The use of the figure is to arrest the attention. Hyperbola is the basis of many metaphors. Thus, we call Nero 'a monster;' Tamerlane, 'a tiger;' and so on.

HYPERBOLANS (that is, dwellers beyond Borne or the North Wind), a name given by the ancients to all the unknown peoples of the West and North. The Greeks imagined the country north of the Rhinean (generally supposed to be the Ural) Mountains to be inhabited by the H., and their residence was gradually referred to more distant regions; but it was universally supposed that, as the favourites of Apollo, they enjoyed a terrestrial paradise, a bright sky, and a perpetual spring, a fruitful land, and everlasting youth and health.

HYPERICACEœ, or HYPERICINÆ, a natural order of exogenous plants, containing about 30 known species, trees, shrubs, and herbaceous plants, widely distributed over the world, and in very different climates, but particularly numerous in North America. The leaves are generally covered with pellicid dots, and the edges of the leaves, sepals, and petals bordered with black glands. The stamens are united at the base, and are spread in from 3 to 5 bundles. The species of Viens yield a substance resembling gamboge. Many of the H. belong to the genus Hypericum, or St John's Wort, of which some species are common natives of Britain, adorning woods, heaths, &c., with small bright yellow flowers. H. calycinum, a spreading shrubby species, naturalised in some places in Britain, has flowers more than two inches in diameter. H. perforatum, the common true St John's Wort, has astringent properties, and is used for gaggles and lotions, and internally in dysentery, &c., although not recognised in the pharmacopœia.

Superstitious notions are connected with it in many parts of Europe, particularly when gathered on the day of St John the Baptist.—H. Aubrodenum (or Androscennum officinale), commonly called Tutsan, a pretty common native of Britain, with berry-like fruit, was once in great esteem as a vulnerary. Its English name is Tutsan, from the French toutsaint, all whole.

HYPERION. See TITANS.

HYPERSTHENÉ, a mineral closely related to augite and diabase. It is a bisulphide of iron and magnesia. It is intensely black, but sometimes faint greenish, and is often disseminated. Viewed in one direction, with reference to its cleavage planes, it is copper-coloured, in another it is dark brown. When cut and polished, it is cherry-red, with a pearly lustre, and is valued for rings, brooches, &c. The finest specimens are brought from the coast of Labrador, although it is found in Norway, Sweden, Germany, Scotland, &c. It is sometimes found in connection with felspar, forming Hypersthené rock, a rare kind of trap rock.

HYPERTRICHISM (Gr. over-nourishment) is the term applied in medicine to the enlargement of certain organs of the body. The best examples of this change are seen in the muscular system, where it may occur altogether independently of disease. The huge bosses of flesh that stand prominently forward in the arm of a blacksmith or of a pugilist, and in the leg of an opera-dancer, are illustrations of hypertrophy, where the general health remains perfect. In double organs, such as the kidneys and lungs, if the organ on one side degenerates through disease, the organ on the opposite side is often found to enlarge and carry on its functions. In these cases, hypertrophy is an effect of disease, but is at the same time a resource of nature to preserve life.

There are, however, cases in which the hypertrophy has a hurtful instead of a conservat
HYPHASIS.—HYPOCHONDRIASIS.

strict, as, for example, hyperthyroidism of the thyroid gland, constituting the disease known as goitre or brood, and, hyperplasia of the prostate gland, of the spleen, &c. The following are, according to Mr Paget, the conditions which give rise to hyper-

thyroidism: 1. The increased exercise of a part in its healthy function; 2. An increased accumulation, in the blood, of the particular material which a part appropriates in its nutrition or in secretion; 3. An increased influx of healthy blood. In hyperthyroidism of the muscular tissue, the first and third of these conditions are present. In hyperthyroidism of the fatty tissue, constituting obesity, there is an excess of fat or of its chief elements in the blood.

HYPHASIS. See STYLE.

HYPHEEN (Gr. together, in one), the name given to a mark in writing, thus (-), indicating that two words or syllables are to be connected; e.g., bull-fight.

HYPNOTISM (from the Greek word hypnos, sleep) is a term invented by the late Mr Braid, of Manchester, to designate certain phenomena of the nervous system which in many respects resemble those which are induced by animal magnetism, but which clearly arise from the physical and psychical condition of the patient, and not from any emanation proceeding from others. The following are his directions for inducing the phenomena, and especially the peculiar sleep-like condition of hypnotism. Take a silver lancet-case or other bright object, and hold it between the fingers of the left hand, about a foot from the eyes of the person experimented on, in such a position above the forehead as to produce the greatest strain on the eyes compatible with a steady fixed stare at the object. The patient must be directed to rivet his mind on the object at which he is gazing. His pupils will first contract, but soon dilate consider-

ably; and if, after they are well dilated, the first and second fingers of the operator's right hand, extended and a little separated, are carried from the object towards the eyes, the eyelids will most probably close with a vibratory motion. After ten or fifteen seconds have elapsed, it will be found that the patient retains his arms and legs in any position in which the operator places them. It will also be found that all the special senses, excepting sight, are at first extremely exalted, as also are the muscular sense and the sensibility of heat and cold; but after some time the excitation of the vision is followed by a state of depression far greater than the torpor of natural sleep. The patient is now thoroughly hypnotised. The rigidity of the muscles and the prof-
found torpor of the nervous system may be instantly removed, and an opposite condition induced by directing a current of air against the muscles which we wish to render limber, or the organ we wish to excite to action; and then by mere repose the senses will speedily regain their original condition.

If a current of air directed against the face is not sufficient to arouse the patient, pressure and friction should be applied to the eyelids, and the arm or leg sharply struck with the open hand.

For the careful analysis of a large number of experiments, Mr Braid is led to the conclusion, that by a continual fixation of the mental and visual eye upon an object, with absolute repose of body and general quiescence, a feeling of stupor supervenes, which renders the patient liable to be readily affected in the manner already described. As the experiment succeeds with the blind, he considers that it is not so much the optic, as the sentient, motor, and sympathetic nerves, and the mind, through which the impression is made.

Many of the minor operations of surgery have been performed on patients in the hypnotised state without pain, and hypnotism has been successfully employed as a therapeutic agent in numerous forms of disease, especially in affections of the nervous system. An interesting memoir on Hypnotic Therapeutics was published by Mr Braid in the 17th volume of The Monthly Journal of Medical Science (1853).

HYPOCOAST, a form of furnace much used by the Romans, for the purpose of heating baths and apartments. The fuel is placed in a chamber under the floor, and the smoke and heated air are made to circulate round the walls and under the floor, by means of hollow tubes, or a hollow lining. The full benefit of the fire is thus obtained, in place of a large portion of the heat being allowed to escape, as it does, in the case of an open fireplace, up the chimney. The Romans invariably used this form of furnace for heating their dwelling-houses, and in all the Roman houses which have been discovered in this country, remains have been found of the hypocaust. It is now coming into use for heating the so-called 'Turkish Baths.'

HYPOCHELÆRIS, a genus of plants of the natural order Compositae, sub-order Cichoraceae, of which one species, H. radiata, or Long-rosted Cat's-ear, is extremely common in meadows and pastures in Britain. Its leaves are all radical, and appear in the ground, resembling in form those of the dandelion, but rough; the stem is branched, the flowers not unlike those of the dandelion, but smaller. Cattle eat this plant readily, and its abundance is not deemed injurious to pasture or fodder.

HYPOCHLOROUS ACID (ClO) is a dark red fluid, which, at a temperature of about 70°, becomes converted into an orange-coloured gas, which very readily explodes into its ultimate constituents. A watery solution of this gas has a penetrating, chlorine-like odour, a caustic action on the tongue, colours the skin brown, and if applied for any length of time, causes it to ulcerate. It is the active ingredient of the different bleaching-powders and salts. Its salts—the hypochloritones—present very much the same odour as the acid. Their solutions bleach organic pigments, such as hímus and indigo, and are employed largely as bleaching agents.

HYPCHO'NDERS (Gr. hypo, under; chondros, a cartilage) are the two lateral and superior regions of the Abdomen (q.v.) under the cartilages of the false ribs, and to the right and left of the epigastric impression.

HYPCHONDRIASIS (so called from its sup-
p posed connection with the hypochondriacal regions of the abdomen), a disease characterised by extreme increase of sensibility, palpitations, morbid feel-
ings that simulate the greater part of diseases, exaggerated uneasiness and anxiety, chiefly in what concerns the health, &c. In extreme cases it becomes a species of insanity (see below). The disease is intimately connected with, if not caused by, disorder of the digestive functions. See IN-

divergence.

Hypochondriacal Insanity.—When sombreness of disposition and anxiety concerning personal comfort become exaggerated, and attention is directed chiefly to the state of the health, it sometimes becomes common hypochondriasis. When it passes beyond the control of the will, when the whole mind is directed to the state of the system, or to particular organs, and exalts and misinterprets sensations, the disease is called hypochondriacal insanity.

The disease may be described as the engrossment of the attention by false impressions conveyed, or
HYPOSTASIS—HYPOSTHESIS.

HYPOSTASIS (Gr. Hypostasis, subsistence), the term employed by Greek theological writers to designate the distinct subsistence of the three persons of the Trinity. Originally, the meaning of the word was unsettled. It was used by the Fathers of the council of Nice, in the sense of ousia, essence or substance, but the great exponents of philosophy supplied the most formidable weapon to the semi-Arians in the controversy about the Homoousian (q. v.). The use of the word hypostasis, however, was settled at a synod held by Athanasius in 357, in which it was fully distinguished from ousia, and explained as synonymous with prosopon, which the Latins rendered by persona, person. From this time, the word was adopted into the theological language of the Latin Church, in which it is used indiscriminately with persona.

HYPOSTATIc UNION (Gr. Hypostasis, person), a union of natures or substances so intimate as to constitute one undivided person. The term, derived from the Greek word Hypostasis, is used to denote the union of the divine and human natures in Christ, in virtue whereof, while each nature is complete, even after union, yet each merges its separate personality in the undivided person of the God-man, to which all the attributes of the natures, whether divine or human, are incident. This form of expression was devised for the purpose of excluding the doctrine of a mere moral union held by Nestorians. See MONOPHYSITES, NESTORIANS, TRINITY.

HYPOTHEC, a term in the law of Scotland, but not used in England, to denote a lien or security over goods in respect of a debt due by the owner of the goods. Thus, a landlord has a hypothec over the furniture or crops of his tenant in respect of the current rent; so a law-agent or attorney has a hypothec over the title-deeds of his client in respect of his account or bill of costs. In England, these rights are called liens, and are not so liberally allowed. See Paterson's Comp. of E. and S. Law, p. 594. There are also a hypothec, or hypothec of seamen over the freight in respect of their wages.

HYPOTHETICATION is the pawning of a ship for necessary, or to raise money in some critical emergency.

HYPOTHETUSE, the name of that side in a right-angled triangle which is opposite to the right angle. The well-known property of the hypothuse, that the square described on it is equal to the sum of the squares described on the other two sides, is proved in the famous 47th proposition of the first book of Euclid's Elements, and has, in the sixth book, been generalized into the following form: The figure described on the hypothuse is equal to the similar figures described on the other two sides. It is said that the 47th proposition was discovered by Pythagoras, who was so overjoyed at his good fortune, that he sacrificed a hecatomb to the Museus. Camerer, in his edition of Euclid, gives seventeen different demonstrations of this proposition.

HYPOTHESIS. In endeavouring to explain natural phenomena, we have often to assume a cause, which, in the first instance, we do not know to be the real cause, but which may be established as such when we find that its consequences agree with the phenomenon to be explained. Every genuine theory was at one stage a mere conjecture, and became a true theory in consequence of being proved or verified by the proper methods. Thus, when it occurred to Newton that the force of gravity on the earth, as exemplified in falling bodies, might extend to the distance of the moon, and might be the power that compelled it to circle round the earth, instead of going off in a straight line through space, the suggestion was only an hypothesis, until such time as he was able to show that it accounted exactly for the facts, and then it became a theory. A difference of opinion has arisen as to what constitutes a legitimate hypothesis, there being manifestly some necessary limits to the process of imagining possible causes. The case that has chiefly contributed to make this a question is the celebrated undulatory theory of light, a theory, or hypothesis—rather, remarkable not only for the extent to which it explains the facts, but for having led to the discovery of new facts by way of inference from the theory itself. Notwithstanding all this amount of coincidence, the ethereal substance whose undulations are supposed to constitute light in its passage from the sun to the earth, is not known to have a real existence, it is an imaginary element, so
HYPONANTHINE—HYRACOTHERIUM.

HAPPILY CONCEIVED as to express with fidelity a series of extremely complicated phenomena. This was not the character of Newton's hypothesis as to the motion of the moon; the power supposed by him (the earth's gravity) was an actual or existing force, and all he did was to suggest that it extended as far as the moon. Accordingly, M. Auguste Comte and Mr. J. Milner laid it down that in a sound scientific hypothesis, the cause assigned to the phenomenon in question should be either a real cause, or capable of being ascertained to be a real cause, and that the liberty given to the scientific inquirer should be confined to imagining its operation in a particular sphere, and the law and amount of its operation, since both these could be verified by experiment and calculation. On the other hand, Dr Whewell has contended, that an amount of agreement with observed facts, such as has been exemplified by the indulatory hypothesis, is sufficient to establish not merely an hypothesis, but a theory, at least until such a time as some discordant facts arise, when the theory must be modified or abandoned. But whatever name be given to this class of suppositions, it is evident that they must be deemed inferior in scientific value to the other class of explanations, where no cause or agent is assumed but what is actually known to exist, and where the only question is, the presence of that agent in such manner and amount as to tally with the observed facts. Gravity, heat, electricity, magnetism, are established, natural agents, and when we assume any one of these as the cause of some phenomena, we are on safe ground so far, that if it be once shewn that they are actually operative in the case we are dealing with, and that their calculated effect exactly coincides with the observed effect, the explanation is complete and final; no subsequent discovery can disturb a conclusion established in this way. But if we have to assume the very agency itself, or to imagine a power that we have no experience of, the coincidence between the laws of the assumed agency and the laws of the phenomena produces at best but a temporary or provisional evidence, which is liable to be superseded whenever a still better imagined machinery shall be brought forward. Thus, in the case of light, the first hypothesis, that of Newton himself, was a stream or shower of corpuscles; this gave way to the indulatory ether, whose merit lay in embracing the cases more closely; but we have no security against the ultimate preference of some third supposition which shall replace the second, as that did the first; while, perhaps, a day may come when an agency shall be proved capable of explaining the phenomena. Even granting that we must sometimes assume an unknown agent (when an effect seems to be beyond the power of all the recognised forces), yet, in ordinary researches, it is considered a grave objection if the assumed agent be of such a subtle or occult nature, or so far removed from observation, that its existence does not admit of being proved. Such was the doctrine of the Cartesian vortices, and such are any hypotheses as to the shapes, sizes, and distances of the ultimate atoms of matter. Such also is the doctrine of nervous fluids, whereby the impulses of mind are supposed to be propagated between the brain and the other parts of the body.

HYPONANTHINE, a substance found in the spleen and muscles of the heart of man, and in the spleen and blood of the ox. It is a white crystalline powder, almost insoluble in cold hydrochloric acid, very slightly soluble in boiling alcohol, and requiring for solution in water 1099 equivalents of cold, or 180 of boiling water. Its solution has a neutral re-action.

HYPSILANTIS. See YPSILANTI.

HYRACCREUM, a peculiar substance found in the crevices of the rocks of Table Mountain, Cape of Good Hope. It is one or more of the excreta of the Cape Hyrax (Hyrax Cynocephalus). Hyraceum is a blackish-brown viscous material, not unlike soft pitch, having a strong and offensive taste, not unlike castoreum, for which it has been used as a substitute in medicine. At one time, so large a quantity was found as to suggest the idea of its being used as a manure, but the supply was soon exhausted, and only a small quantity is now imported, to meet the demand of the curious pharmacist.

HYRACOTHERIUM, a genus of fossil Pachydermata, belonging to the division Perrysiodactyla, the animals of which are characterised by having an odd number of toes. The genus was founded by Owen on the fragmentary remains of two species found in Lower Eocene strata; a third species from the same beds has been since described by him from more complete materials, under the name *Pliophius vulpecus*; he considers it only a subgenus, and as we can see no characteristics to separate it generically from the other two, we place it here as a true hyracothere. The fossil was discovered in a nodule from the Roman cement bed of the London Clay near Harwich. It is the most complete Eocene mammalian fossil of the London Clay. It consists of an entire skull and a portion of the rest of the skeleton, including the right humerus and femur, a great part of the left femur, the left tibia, and three metataral bones, apparently of the same foot, besides fragments of pelvis, ribs, and vertebrae. The head (fig. A 1 and A 2) is 5 inches long, and 2 inches 2 lines broad; it is slender, tapering gradually from the zygomatic region to the muzzle; the upper outline is straight; the bony rim of the orbit is incomplete behind for about one-fifth of its circumference. The narrow skull and incomplete orbit ally it to the Paleotherio; the same form of orbit occurs also in the rhinoceros, and more exactly in the tapir. The straight contour of the skull, and the structure of the nasal aperture, show affinities with the horse and hyrax. The third molar of the upper jaw (fig. A 3) shows the structure
HYRAX—HYSSOP.

of the teeth. The teeth, as well as the form of the lower jaw, tell plainly of the herbivorous character of the hyracotheres. The bone of the leg exhibit usagulate affinities, and their form and proportions are between those of the hyrax and the tapir. The second species was founded on a mutilated cranium (fig. B 4, A, B, 2), rather larger than the above, from the cliffs of London Clay near Herne Bay. It shows a skull very like the first species, though broader at the orbital region. The third molar tooth (fig. B 3) has a larger number of cones than the same tooth in the first species. The third species was founded on several teeth which belonged to a smaller animal than either of the others, found in the Eocene sand underlying the Red Crag at Kyston, in Suffolk. The molar (fig. G 2) exhibits a structure similar to that of the others figured. From the same deposit were obtained two teeth belonging to a lower jaw, one of them, the third molar, still in its socket, and having a fragment of the jaw attached to it (fig. C 1). These teeth were considered by Owen to belong to a quadrumaneous animal, and were described by him as Macacus Ecorum, *at once the first terrestrial mammal which has been found in the Eocene deposits,—a high-priest, and a quadrumaneous animal hitherto discovered in any country in Tertiary strata so old as the Eocene period.* Since its publication, speculative geologists have made good service of this *monkey,* says Owen has, however, recently stated that the species were probably *Macacus Unicrocum.*

HYRAX. See DAMAN.

HYCAR'NIA, a district of ancient Asia, bounded on the N. by the Caspian Sea and the Ochus (sometimes called, in consequence, Hyrum Aprae, *a country*), on the E. and S. by the Elburz Mountains, which separated it from Parthia, and on the W. by Media. It corresponds with the modern Mazenderan and Asterabad. With the exception of the coast districts, and the valleys among the hills, which produced corn, oil, and wine, it was not a fertile region; dense forests prevailed, through which roamed multitudes of savage animals, the Hyrcanian tiger in particular being celebrated. The inhabitants were of the same name as the Hyrcani, and were noted for their wild and rude character.

HYRCANUS, the name of two Jewish high-priests and princes of the Asmonean family.—1. JOANNE H., son of Simon Maccabaeus, who ruled 136—106 B.C., was at first tributary to the Syrians; but on the death of Antiochus, made himself independent, subdued the Samaritans on the north, and forced the Idumeans on the south to adopt the laws and customs of the Jews. He also concluded an alliance with the Romans, or rather confirmed that which his father Simon had previously made; built the strong fortress of Baris on the north-eastern angle of Mount Moriah, and extended his territories almost to the ancient limits of the Davidian monarchy. He is also said to have founded the Samhedrim (v. y.). Originally a Pharisee, he subsequently attached himself to the party of the Sadducees, who were anxious to keep on good terms with the Romans, and he contributed to the turbulent religious patriotism of the Jewish masses. H. was, comparatively speaking, a just and enlightened ruler, and the country enjoyed great prosperity during his reign. He left five sons, two of whom, Aristobulus and Alexander, and with the title of king—

2 HYRCA'NUS II., son of Alexander, and grandson of the preceding, was a feeble prince. On the death of his father (78 B.C.), he was appointed high-priest by his mother Alexandra, who ruled Judea herself for the next nine years. After her death (69 B.C.), his younger brother, Aristobulus, a braver and more energetic man, seized the government, and forced H. to withdraw into private life. Induced by the Idumean, Antipater, and aided by Aretas, king of Arabia Petraea, he endeavoured to win back his dominions, but was not successful until Pompey began to favour his cause. After some years of tumultuous fighting, Aristobulus was poisoned by the partisans of Ptolemy (49 B.C.), who had for some time possessed, if he had not enjoyed, the dignity of high-priest and ethnarch, was now deprived of the latter of these offices, for which, in truth, he was wholly incompetent. Cæsar (47 B.C.), on account of the services rendered to him by Antipater, made the latter procurator of Judea, and thus left in his hands all the real power, H. busying himself only with the affairs of the priesthood and temple. Troubles, however, were in store for him. Antipater was assassinated, as Antigonus, son of Aristobulus, with the help of the Parthian king, Orodes I., invaded the land, captured H. by treachery, cut off his ears, and thus disqualified him for the office of high-priest, and removed him off to Seleucia in the Tigris. Some years later, Herod, son of his old friend Antipater, obtained supreme power in Judea, and invited the aged H. home to Jerusalem. He was allowed to depart, and for some time lived in ease and comfort, but falling under suspicion of intriguing against Herod, he was put to death (30 B.C.).

HY'RTL, JOSEPH, a distinguished anatomist, was born in 1811 at Eisenstadt, in Hungary, studied at Vienna, and early acquired eminence both as a scientific anatomist, and upon account of the extreme beauty of his anatomical preparations. He became Professor of Anatomy in Prague in 1837, and at Vienna in 1845. Whilst yet a student, he enriched the Anatomical Museum of Vienna with many preparations. He has contributed not a little to the progress of comparative anatomy, especially that of fishes, and has made the anatomy of the ear a subject of very particular investigation. Besides many articles in medical and the scientific journals, he has published a number of works on the subjects above indicated; and a Lehrbuch der verglichenen Naturgeschichte des Menschen (2 vols. 1847; 4th ed. 1855), which has become a textbook in all the German universities, and has been translated into various languages. He has formed a museum of comparative anatomy in Vienna, which promises to become one of the finest in Germany.

HYSSOP(Hysæpus), a genus of plants of the natural order Lobi'ter, distinguished by four straight diverging stamens, and a calyx with 15 ribs. The known species are few. The Common H. (Hysæpus officinalis), a native of the south of Europe and the East. It is found on the Alps of Austria. It is a half-shrubby plant, about 1 foot high, the upper part

![Common Hyssop](Image)
HYSTERIA—HYSSOP SCHOOL OF MUSKETRY.

of the stems quadrangular, the leaves evergreen and lanceolate, the flowers in one-sided whorled racemes. The flowers are generally of a very beautiful blue. It has an agreeable aromatic odour. It has been long in cultivation for the sake of its leaves and young shoots, which are sometimes used for culinary purposes as a seasoning, but more generally in a cured state as a stomachic and carminative. A syrup made with them is a popular remedy for the virtues of H. doux and a volatile oil. It is very doubtful what plant is the H. of the Bible. It has been supposed to be some species of Phytolacca (q. v.), as P. acinoosa, a native of the Himalaya; but of late, strong arguments have been advanced in favour of the common Caper (q. v.)—HEDG. H. is Gratiola officinalis. See GRATIOLA.

HYSTERIA (so called from the Greek word hysteria, the womb) is a disease which simulates so many other diseases, that it is not easy to describe it with the brevity which the limits of this work necessitate.

The hysterical fit or paroxysm—the most marked form or manifestation of the disorder—is almost, though not exclusively, confined to women, and chiefly to young women. In one case, the trunk and limbs are strongly convulsed; the patient struggles violently, retracting and extending her legs, and twisting her body with such force that the skin is torn. In two or four strong persons is often required to prevent a slight and apparently feeble girl from injuring herself or others. 'The head,' says Dr. Watson in his Lectures, 'is generally thrown backwards, and the throat projects; the face is flushed, the eyes are closed, the pulse is tremulous; the nostrils distended; the jaws often firmly shut; but there is no distortion of the countenance. If the hands are left at liberty, she will often strike her breast repeatedly and quickly, or carry her fingers to her throat, as if to remove some oppression there; or she will sometimes tear her hair, or rend her clothes, or attempt to bite those about her. After a short time, this violent agitation is calmed; but the patient lies panting, and trembling, and starting at the slightest noise or the gentlest touch; or sometimes she remains motionless during the remission, with a fixed eye; till all at once the convulsive movements are renewed; and this alternation of spasm and quiet will go on for a space of time that varies considerably in different cases; and the whole attack frequently terminates in an explosion of tears, and sobs, and convulsive laughter.

In another less frequent form of the affection, the patient suddenly sinks down insensible and without convulsions: after remaining for some time in this state, with flushed cheeks, a turgid neck, and irregular breathing, she recovers consciousness, but remains for some time depressed in spirits and fatigued.

During the attack, especially in the first variety, the patient complains of uneasiness in the abdomen, and of a sensation as if a ball were rolling about, and rising first to the region of the stomach, and then to the throat, where she feels as if she were being choked. The abdomen is distended with wind, which moves with a loud rumbling sound along the intestinal canal, and is often discharged by belching. Towards the close of the fit, but more commonly after it is over, a large quantity of pale limpid urine is discharged.

In many respects, this affection resembles Epilepsy (q. v.): resembling to Dr. Marshall Hall, the most essential difference is this: that in hysteria, much as the larynx may be affected, it is never closed; while in epilepsy, it is closed. Hence, in the former, we have heaving, sighing inspiration; and in the latter, violent, ineffectual efforts at expiration.

The hysterical fit varies in duration from a quarter of an hour or less to many hours.

The persons who suffer from hysteria are commonly young women in whom the process of menstruation is disorders, or who are otherwise naturally feeble, or have been debilitated by disease or want; and in patients of this kind, the hysteria, or the hysterical tendency, is apt to show itself in bustling or fatuously. Many of the most important diseases, that the physician has often great difficulty in determining the true nature of the case. Among the disorders that may be thus simulated by hysteria are, inflammation of the peritoneum (or Peritonitis, q. v.), various forms of palsy, inflammation of the larynx (or Laryngitis, q. v.), inability to swallow (or Dysphagia), painful affection of the breast, disease of the lip and knee joints, and disease of the spine. Many of these cases of pseudo-disease come to a sudden favourable termination under some strong mental or moral emotions. Those who are old enough to recollect the morbid religious excitement that prevailed at the time when Irving and his followers were in the 'unknown tongue,' can hardly fail to remember the remarkable, or, as many regarded it, the miraculous cure of a young paralytic girl, who was made to believe that if, on a certain day, she prayed for recovery with sufficient faith, her prayers would be answered, and she would recover at once. She did so, and her palsy instantly disappeared. This case, which was regarded by the believers in the movement as a direct answer to prayer, and as inaugurating a new era of miraculous cures, admits of easy and rational explanation by some psychologists. There are various instances on record where, in a similar way, an alarm of fire has instantly cured an hysterical paralysis that had lasted for years.

In the cases already noticed, the patient is not guilty of wilfully deceiving the physician; but in other instances they are found to practise the most remarkable impostures, pretending by various frauds to be suffering from spitting of blood, from stone in the bladder, &c., or to be living without food of any kind.

Hysteria is a very troublesome affection to deal with, because it is very readily induced by example, or by the belief that it is compatible with moral and secular good. If, in a hospital ward or in a factory where many young women are congregated, one girl goes off in a fit, all the others who may happen to have the same disorder will probably come on. An example. In such cases, a decided order that the next girl who is attacked shall be treated with the actual cautery, or even with the cold affusion, will often have a marvellous effect in checking the spread of the disorder.

During the fit, the treatment to be adopted is to prevent the patient from injuring herself, to loosen her dress, and to admit an abundance of fresh cool air; to dash cold water upon the face and chest, and, if she can swallow, to administer a couple of ounces of the aseetifia mixture, or a drachm of the ammoniacum tincture of valerian in a wine-glass of water. After the paroxysm is over, the patient should have an active purge, and the bowels should be kept properly open by aloe emetic pendrants; and the shower-bath, preparations of iron, and tonic treatment generally should be adopted, and all abnormal bodily and mental excitement, such as late parties in her parents, novel-reading, &c., should be carefully avoided.

HYSTRIX AND HYSTRICHENE. See PORCUPINE.

HYSSOP SCHOOL OF MUSKETRY. See MUSKETRY, SCHOOL OF.
I

THE ninth letter in the alphabeta of Western Europe, was called by the Greeks ιοτα, after its Semitic name (Heb. Jed), which signifies 'hand.'

The oldest forms of the letter, as seen in the Phoenician and Samaritan, have a rude resemblance to a hand with three fingers; but by gradual simplification, the character came to be the smallest in the alphabet, and 'ιοτα' or 'ιοτ' is a synonym for a tribe. The original sound of the letter, and that which is considered its proper sound in all languages except English, is that given to Eng e in sea; with this power, it forms one of the fundamental vowels i, u (see A. and Letters). What is called the long sound of i in Eng is really the diapason or rapidly pronounced. The power that the vowel i, followed by another vowel, has of turning the preceding consonant into asubant, has been noticed in regard to the letter C (q. v.); further instances may be seen in such French words as rage, siege, from Lat. rubra, simia. In Lat., there was but one character for the vowel i and the semi-vowel y now denoted by the character j. See J.

IAMBIC VERSE, a term applied, in classic prose, and sometimes in English, to verses consisting of the foot or metre called iambus, consisting of two syllables, of which the first is short, and the second long (- -). Archibulus (q. v.) is the reputed inventor of iambic verse. The English language runs more easily and naturally in this metre than in any other. See Metre, Verse.

Thor ståg [at éve] i had drük / hér fill.

Lady of the Lake.

IAMBICUS, the proper name of several persons in classical antiquity, as—1. A king of Erima, whose son, Iamblichus of Chalcis, was sent by the Empert. Septimius Severus to the court of Elagabalus to be his tutor; 2. A Syrian freeman, who flourished at the end of the reign of Trajan and beginning of that of M. Aurelius (117-180 a. D.). He was instructed by a Babylonian in the language, manners, and literature of Babylon, and wrote the Babylonian, or Loves of Rhodanis and Simionis, in 16 or 29 books, which has been preserved by Photius, c. xeiv, and Les Allatius. It is the oldest of the novels of antiquity which has reached the present day, but is not of any great merit either as to style or plot. 3. A philosopher who flourished under Constantine about 310 a. D., born of an illustrious and wealthy family at Chalcis, in Cade Syria, pupil of Anaxiimenes and Porphyry, and of the Neo-Platonic school of Plotinus, whose doctrines he extended. Little is known of his life; but he was followed by a numerous school, who listened with enthusiasm and respect, and who thought that he was inspired, had intercourse with the gods, and could divine and perform miracles. This gave him immense credit. His doctrines were a syncretic mixture of Pythagorean and Platonic ideas, mixed with superstition and magic, and the supposed manifestation of God by ecstasies, and a communication with the spiritual world by ceremonies. One of his great works; On the Choice of Pythagoras (Peri Air Rosen Pythagorou) consisted of 10 books, of which there remains the

1st. A Life of Pythagoras, filled with prodigies, and evidently written against Christianity. 2d. An Exhortation to Philosophy (Proteptikoi Logoi eis Philosophian), an ill-arranged introduction to Plato. 3d. On the Common Knowledge of Mathematics (Peri Koines Mathematicas Epistemen), full of fragments of Pythagoras, Philolaus, and Archytas. 4th. On the Arithmetical Introduction of Nicomachus. The 5th and 6th books are lost. 5th. The Theology of Arithmetic (To Theologonchema te Arithmetikon; the 6th, The History of Music; the 7th, Geometry; the 10th, On the Study of Heavenly Bodies. He also wrote a work on the Soul, commentaries on Plato and Aristotle, another on the complete Chaldæan Philosophy, another on Beginnings, and one on Sacred Images, in which he affirmed that the gods resided in their statues. His celebrated work on the Mysteries (Peri Maisterion) is, however, disputed; it is supposed by Meiners not to be written by I.; but is asserted by Tennemann to be the work of another author. It is drawn up as the answer of Abammon, a priest, to a letter addressed to his pupil, Anelo, by Porphyry. It contains many Egyptian doctrines, and esoterical explanations derived from the Hermetic Books, the writings of Bitis and others, mixed with Pythagorean and Neo-Platonic ideas. The style of I. is not careful, and inferior to Porphyry. I. is supposed to have died at Alexandria, 333 A. D.—Several other writers of this name are known, as a younger philosopher of the Neo-Platonic school, born at Apanea, and supposed to be a nephew of the preceding, praised by Libanius to Julian the Apostle; another, son of Himerius, mentioned by the same author, and a physician at Constantinople.

Eudoci, Violeum, p. 244; Eunapius, Vit. Philo.

IBARRA, or SAN MIGUEL DE IBARRA, a town of Ecuador, South America, in the department of Quito, and 60 miles north-east of the town of that name. It is situated on the northern base of the volcano of Imbabura, is well built, and carries on manufactures of wool and cotton. Pop. estimated at about 10,000.

IBERIA. See Hispania and Georgia.

IBERIS. See Cadiz.

IBEX, the ancient name of the Bouquetin (q. v.), or Steinbock of the Alps; and now, according to some zoologists, of a genus of the goat family, or sub-genus of goat, having the horns flat, and marked with prominent transverse knots in front, whereas those of the true goats are compressed and keeled in front, and rounded behind. The species are all inhabitants of high mountainous regions. The I. of the Caucasus and the I. of the Pyrenees differ a little from the I. of the Alps, and from one another, but the differences may perhaps be regarded as those of varieties rather than of species.

The conventional ibex represented in Heraldry resembles the hercal antelope in all respects, except that the horns are straight and serrated.
IBICUI-ICE.

IVICUI, or IBICUY, an important affluent of the Paraguay (q.).

IBIS, a genus of birds of the family Ardeidae, or, according to some ornithologists, of Scapulideae, and perhaps to be regarded as a connecting link between them. The bill is long, slender, curved, thick at the base; the point rather obtuse; the upper mandible deeply grooved throughout its length. The face, and generally the greater part of the head, and sometimes even the neck, are destitute of feathers, at least in adult birds. The neck is long. The legs are rather long, naked above the tarsal joint, with three partially united toes in front, and one behind; the wings are moderately long; the tail is very short.

The SACRED I., or EGYPTIAN I. (Ha! religiosa), is an African bird, two feet six inches in length, although the body is little larger than that of a common cow. The Glossy I. (Pfl. falcinellus) is a smaller species, also African, but migratory, northwards into continental Europe, and occasionally seen in Britain. It is also a North American bird. Its habits resemble those of the sacred ibex. Its colour is black, varied with reddish brown, and exhibiting fine purple and green reflections. It has no loose pendent feathers. The WHITE I. (H. cleya) is a species with pure white plumage, abounds on the coasts of Florida. Audubon saw multitudes on a low islet, and counted 47 nests on a single tree. The BLACK-NECKED I. (H. nigripennis) is a large Australian bird of fine plumage, remarkable for still naked yellow feather-shafts on the neck and throat.

The SACRED Ibis, one of the birds worshipped by the ancient Egyptians, and called by them Ihab or Hbif, and by the modern Egyptians Abu-Hannes (i.e., Father John), is a bird with long beak and legs, and a heart-shaped body, covered with black and white plumage. It was supposed, from the colour of its feathers, to symbolise the light and shade of the moon, its body to represent the heart; its legs described a triangle, and with its beak it performed a medical operation; from all which esoteric ideas it was the avatar of the god Thoth or Hermes (see Hermes), who escaped in that shape the pursuit of Typhon, as the hawk was that of Ra, or Horus, the sun. Its feathers were supposed to scare, and even kill, the crocodile. It appeared in Egypt at the rise, and disappeared at the inundation of the Nile, and was thought, at that time, to deliver Egypt from the winged and other serpents which came from Arabia in certain narrow passes. As it did not make its nest in Egypt, it was thought to be self-engendering, and to lay eggs for a lunar month. According to some, the basilik was engendered by it. It was celebrated for its purity, and only drank from the purest water, and the most strict of the priesthood only drank of the pools where it had been seen; besides which, it was supposed, though not to entertain the most inviolable love of Egypt, and to die of self-starvation if transported elsewhere. Its flesh was thought to be incorruptible after death, and to kill it was punishable with death. Ibises were kept in the temples, and unmolested in the Jewish temple of cities. After the destruction of the temple, and especially at Jerusalem, they were much in use, and were mummified, and there is no animal of which so many remains have been found at Thebes, Memphis, Hermopolis Magna, or Edfum, and at Ibis or Hebron, fourteen miles north of the same place. They are sometimes placed in the conical shape, the wings spread out, the legs bent back to the breast, the head placed on the left side, and the beak under the tail; were prepared as other mummies, and wrapped up in linen bandages, which are sometimes placed in papyrus externally. At Thebes, they are found in linen bandages only; well preserved at Hermopolis in wooden or stone boxes of oblong form, sometimes in form of the bird itself, or the god Thoth; at Memphis, in conical sugar-loaf-shaped red earthware jars, the tail downwards, the cover of cover form, cemented by lime. There appear to be two sorts of embalmed ibises—a smaller one of the size of a corncrake, very black, and the other black and brown. The last is usually found sometimes with its eggs, and with its insect food, the Pinicola pinosa, Aka refiza, and portions of snakes, in the stomach. It is said to resemble the I. of India rather than the African. They were eaten by the Egyptians. Cretan ibises are mentioned in Homer, and are compared to his boxer, to the same as an English cock. The ibises are sometimes called Egyptian doves. According to Strabo, The ibis was the bird of the Egyptians, and the head of an Egyptian army in 1825, with the view of reducing it under the power of Mohammed Ali; but the intervention of the great powers in the affairs of Greece compelled him to abandon this enterprise in 1828. Mohammed Ali having commenced the design of adding Syria to his dominions, Ibrahim crossed the Egyptian border with an army in October 1831, took Acre by storm, and quickly made himself master of the whole of Syria. A peace was concluded on 4th May 1833, the Turks not only had to give up Syria, but also making over Adana to Ibrahim personally, on a kind of lease. When war broke out again between Mohammed Ali and the sultan in 1839, Ibrahim was again successful, totally routing the Turks in the great battle of Elasium on 24th June. The interference of the great powers, eventually compelled him to relinquish all his Syrian conquests, and to return to Egypt, suffering, during his passage through the desert, the most terrible hardships and losses, whilst the attempt to elevate Egypt to complete independence came to an end. In 1848, when the agia paacha had sunk into absolute despotage, I. went to Constantinople, and was installed by the Porte as protector of the Nubians; but on 8th November he was assassinated at Cairo. He was succeeded, not by any of his own children, but by Abbas Pasha (q.v.), the favourite grandson of Mohammed Ali.

IBRAHIL. See Brahily.

ICE is water in the solid form. It is specifically lighter than water, which is just about to freeze, and therefore swells in it. Water, in becoming ice, expands about 9/10 of its volume. The formation of ice takes place generally at the surface of water. This is owing to the peculiarity, that
When water has cooled down to within 7°—4 of freezing, it ceases to contract, as before, with increase of cold, and begins to expand until it freezes; which causes the coldest portions of the water to be always floating on the surface. In some circumstances, however, not very well explained, ice forms at the bottom of rivers, and is called ground-ice.

Water, in ordinary cases freezes at the degree of about 32° on Fahrenheit's thermometer, and 0° on the Centigrade and Reaumur's; but if it is kept perfectly still, it may be cooled to nearly 22° F. below freezing, and still remain liquid. The least shake, however, or the throwing in a solid body, makes a portion of it freeze instantly, and its temperature rises immediately to 32°. Sea-water, and salt water in general, freezes at a lower temperature than pure water; in doing which, part of the salt separates, and the ice, when melted, gives water that is fresher than the original. The colour of pure ice is deep blue, which is only discernible, however, when it is in large masses. It is best seen in the cliffs of a glacier or an iceberg.

It is well known, that mountains, and on mountains of a certain height in all latitudes, there exist immense masses of permanent ice; and even in some districts of Siberia, where a kind of culture is practised, there are found, in the earth above the surface of the earth strata of ice mingled with sand. In sinking a well at Yakutsk, the soil was found frozen hard to the depth of 382 feet, and consisting in some parts entirely of ice. These permanent masses of ice must be classed with rocks and mountains, as among the solid constituents of the globe.

In the lower regions of the torrid zone there is no ice, and in the temperate zones, it is a passing phenomenon. From the polar ice-fields and glaciers which are always protruding themselves into the sea, great floating masses become detached, and form icebergs, floes, and drift-ice. These bergs or mountains of ice are sometimes more than 250 feet above the sea-level. They present the appearance of dazzling white chalk-cliffs of the most fantastic shapes. Fresh fractures have a green or blue colour. From the specific gravity, it is calculated that the volume of an iceberg below the water is eight times that of the protruding part. Icebergs, and floes of floating ice-fields, are often laden with pieces of rock and masses of stones and detritus, which they have brought with them from the coasts where they were first formed. Icebergs lie generally for a great distance towards the equator. These floating masses of ice are dangerous to navigation.

The hardness and strength of ice increase with the degree of cold. In the severe winter of 1740, a house was built of the ice of the Neva at St. Petersburg 50 feet long, 16 wide, and 20 high, and the walls supported the roof, which was also of ice, without the least injury. Before it stood two ice-mortars and six ice-cannon, made on the turning-lathe, with carriages and wheels also of ice. The cannon were of the calibre of 6-pounders, but they were loaded with only ½ lb. of powder, and with hemp-balls—on one occasion with iron. The thickness of the ice was only four inches, and yet it resisted the explosion.

About twelve years ago, Faraday called attention to a remarkable property of ice, since (incorrectly) called Regelation. He endeavoured to account for the fact that two blocks of ice, with flat surfaces, placed in contact, unite into one mass when the temperature of the surrounding air is considerably above the freezing-point, by assuming that a small quantity of water, surrounded on every side by ice, has a natural tendency to contract, and that two blocks of ice placed in contact do not unite unless they are moist, seems to bear out this idea. But J. Thomson gave a totally different explanation of this phenomenon. He showed that the capillary force of the film of water between the two plates is sufficient to account for a pressure equal to the pressure between them; so that from his point of view the phenomenon would be identical with the making of snowballs by pressure; and the formation, by a hydraulic press, of clear blocks from a mass of pounded ice, is observed in fact, and an explanation of which is to be found in the property of ice mentioned below. See Proceedings of the Royal Society, 1860—1861. Faraday, taking up the question again, has shewn that the (so-called) regulation takes place in water as readily as in air, a fact quite inconsistent with the action of capillary forces. To this, J. Thomson has replied, shewing, very ingeniously, that the capillary forces he at first assumed are not necessary to a complete explanation of the observed phenomena. See reference above.

Other views of the question are numerous, for instance, that of Persoz, adopted by Forbes, in which ice is considered as essentially colder than water, and when it has once set on ice, so to say, before liquefying, as metals do during the process of melting. This idea, however, has not of late found much support; and it is probable that the true solution of the question is, that Ewald has lately pointed out, to be found in the analogy of the crystallisation of salts from their aqueous solutions.

However that may be, there is no doubt about the following property of ice, theoretically predicted by J. Thomson from the experimental fact of its expanding in the act of freezing, and demonstrated by means of the Piezometer by W. Thomson—viz., that the freezing-point of water, or the melting-point of ice, is lowered by pressure; and the brothers have, with singular ingenuity, applied this to the explanation of the motion of glaciers. That a mass of glacier-ice moves in its channel like a viscous fluid, was first completely established by Forbes. Thomson’s explanation of this motion is of the following nature: In the immense mass of the glacier (even if it were homogeneous, much more so when full of cracks and fissures, as it always is), there are portions relieved to a much greater strain than others. The pressure to which they are subjected is such as corresponds to a melting-point considerably below the temperature of the mass, and the earth below the ice melts, the strain is relieved, and the whole mass is free for an instant to move nearly as a fluid would move in its place. But, the strains being thus for an instant removed, the temperature and pressure of the water are again consistent with freezing—the thin layer of water quickly solidifies, and then matters proceed as before. Thus, at every instant, the strains at different parts of the mass melt it at those places where they are greatest, and so produce the extraordinary phenomenon of a mass which may in common language be termed solid, and even rigid, slowly creeping down its rocky bed like a stream of tar or treacle.

Ice-Trade and Manufacture.—The trade in ice is now one of great and increasing importance. Ice has always been esteemed as a luxury in warm weather; and this early led to the storing of it in winter and preserving it for summer use. The Greeks, and afterwards the Romans, at first preserved snow, closely packed in deep under-ground cellars. Nero, at a later period, established ice-houses in Rome, similar to those in use in most European countries up to the present time. But these means were not sufficient. Richard van Houten, at Amsterdam, was the first who preserved snow for cooling beverages, and they actually established
ICEBERG—ICELAND.

A trade in snow, which was brought to Rome from the summits of distant mountains. The trade in ice in this country has, until lately, been very limited, having been chiefly confined to the supply required by a few of the first-class fishmongers and confectioners—the private residences of the more opulent families being furnished with ice-houses in which a sufficiency is kept for private use. But recently a firm of Americans have made a trade in ice, and this article is in their own cities, which has extended to Europe and Asia, and has, in an incredibly short space of time, attained a surprising magnitude. The export of ice from America was commenced about 1855, by a firm of the name of Tudor, who went into the business from Boston to the West Indies. After persevering against many losses, he succeeded in establishing a trade with Calcutta, Madras, and Bombay; and when he found that the whole of the supply of ice from those places, but also to Hongkong, Whampoa, and Batavia. About fifteen years since, the Wenham Lake Ice Company commenced sending ice to this country from Boston, which is the great American port for shipment of this material; and since then, not only has there been a continually increasing supply, but the success of the Company has been so great as to tempt others into the market, and many cargoes now annually come from Norway and elsewhere.

In America the ice is chiefly collected in the neighbourhood of Boston, Philadelphia, Baltimore, Washington, and New York, and the lakes which supply it form no small part of the property of those whose lands border thereon; these have all been carefully marked out, and the right secured, so that, when the winter comes, and the ice is formed, the harvest begins with great regularity. The ice is cleared from small means of support means of support, and is then made to cut deep parallel grooves in the ice, and these are again crossed by other grooves at right angles, so that the whole of the surface is deeply marked out into small squares, measuring a little more than three feet. A few of these square blocks being detached by hand-saws, the remainder are easily broken off with crowbars, and floated away to the ice storerooms, which are usually built of wood, on the borders of the lake. Some of these are of vast dimensions, and contain vaults of great depth; the walls are double, and sometimes treble, being altogether as much as four feet in thickness, and the space between them is not large enough to render them good non-conductors. The blocks of ice are covered up with sawdust, a layer being placed between each tier of blocks. Many of these ice-houses are made large enough to hold from 40,000 to 60,000 tons of ice. When fully stored, a large quantity of dried marsh grass is trodden in upon the top, to the thickness of several feet, and the doors are then securely closed. The domestic consumption of the United States in 1860 had reached very nearly one million tons, and the export trade exceeds 280,000 tons per annum, of which England takes, on an average, about 20,000 tons, costing £20,000. The total value of the ice which is stored in America has been estimated at £600,000, and if to this we add the ice-trade of Norway, Sweden, Russia, which, from the slight data we possess, is estimated at £600,000, we have the astounding fact, that a value of one million and a half sterling is added to a comparatively small body of water by the mere act of freezing.

Notwithstanding the facilities for importing ice, there is, and always will be, a necessity for procuring it locally if possible. Hence there has been much talent brought to bear in devising means for artificial freezing. See Freezing Mixtures. But until recently, the modes of producing ice artificially were too costly to be practically useful. The desideratum, however, may now be considered as supplied; for machines are constructed by Mr Sebe of Lambeth capable of producing ten tons per day. Such a machine requires steam-power to work it, and its action consists in evaporating ether or another volatile fluid under a high vacuum, thus condensing the vapour to liquid, so as to be used afresh. By this machine, 20° F. below zero (62° of cold) has been easily obtained, and such a machine is now regularly producing large quantities of ice homogeneously under the equator in Peru, where previously ice had never been seen; and others are in use in India and at the Cape in the service of the government, for the use of the troops and hospitals. Another machine was shown in the London Exhibition of 1851 by the French firm of Carré and Co., which, from its extreme simplicity, and the fact that it can be adapted to the humblest kitchen, seems to promise extensive application. The price is from £4 upwards; and as the volatile liquid is only the aqueous solution of ammonia, the cost of working it is very slight. It is believed that an increased demand is all that is required to enable ice to be produced by these machines at a cheaper rate than its transport from the northern part of Europe. The machine-mad ice has the same valuable quality that distinguishes the imported lake ice, viz., its perfect purity, so that pieces of it can be put into the drink that is to be cooled.

ICEBERG. See Ice.

ICE PLANT (Mesembryanthemum [q. v.] crystallinum), an annual herbaceous plant, a native of Africa and South America. It is remarkable for the watery vessels (papula) with which its whole surface is covered, and which have the appearance of granules of ice, and sparkle in the same manner in the sun. It is common as a tender annual in our green-houses, the peculiarity from which it derives its name making it an object of interest. The seeds are used for food in the Madeira Islands. The ashes supply barilla, and the plant is burned on this account in countries where it abounds.

ICELAND, an island in the northernmost part of the Atlantic, on the confines of the Arctic Ocean; in N. lat. 63° 23' to 66° 33', and W. long. 13° 22' to 24° 35', distant about 600 miles from Norway, and 250 from Greenland, 250 from the Faroe Isles, and 500 from Iceland. The interior is described as a land of snow and ice, containing some of the greatest mountains of the kingdom of Denmark. Its extent is about 39,207 square miles; its extreme length from east to west is upwards of 300 miles, its greatest breadth from north to south about 200. Its coasts, particularly on the north and west, are very much broken by bays or fords. In some of the bays are numerous small islands. Iceland is in many respects one of the most interesting parts of the world. Its physical features are very remarkable, and not less so is its history and the character of its inhabitants. It consists in great part of lofty mountains, many of which are active volcanoes; only certain level districts along the coasts, and a few dales, chiefly on the east coast, are inhabited; the whole island is a great field of cultivation, whilst even there scarcely a tree is to be seen, and the climate is unsuitable for grain. The interior of the island is almost entirely occupied with rugged tracts of naked lava and other volcanic products, vast ice-fields in many places connecting its high mountain summits, among which are prodigious glaciers, in some instances descending even to the coast, they and the torrents which gush from them rendering communication between one habited spot and another very difficult and dangerous.
ICELAND.

Yet here has civilization been long established, and the people, necessarily very poor, have cultivated poetry and other departments of literature with great success. The highest mountain in the island is Oraika Jökul, which attains a height of 6420 feet above the level of the sea. It is situated in the south-east, and is connected with a vast mountain mass of which several of the summits are actively volcanic, so less than 3000 square miles being perpetually covered with snow and ice, and from 3000 to above 6000 feet, while all underneath seems to be full of either active or smouldering volcanic fire. The most celebrated volcano is Hecla (q. v.). Kráfla is the most noted group of active volcanoes in the north of the island. The eruptions of Hecla have caused no little devastation, but still more terrible and destructive have been those of Oraika Jökul and other volcanoes of the same mountain mass, which burst forth for the first time within the historic period in 1724. In repeated instances, volcanic islets have been thrown up in the bays and near the coasts of I., which have generally disappeared again within a short time. During the intervals, hot springs in great number, some of which flow gently, and others, called Geysera (q. v.), gush up at intervals and with ebullitions of great violence. Numerous hot springs may, in many places be seen sending up their fumes in a single column, and the Icelanders are accustomed to avail themselves of them for the washing of clothes and other purposes. The water of some is merely lukewarm, whilst that of others is boiling hot, and on some sulphurous. They are subject to great variations, and appear dry up very suddenly. Earthquakes are frequent, and the island suffered very severely from this cause in 1755 and 1783. The winter is not generally as severe as that of Denmark, although more protracted, and it is rather the shortness of the summer and the insufficiency of summer heat, with the superabundance of moisture, than the severity of the winter, which is unfavourable to the growth of corn and plants of many other kinds. In the southern portions of I., the longest day lasts 29 hours; the shortest, 4 hours. In the northern districts, the sun never sets for a whole week in midsummer, and in midwinter never rises above the horizon. Scurvy is a very common kind of disease among seamen and some of the hay-seas are very dry and active. They receive little attention from their owners, whose oxen require almost all the hay and other fodder they can store up for winter. I. poons have now begun to be imported into Britain. Reindeer were introduced into I. by a public-spirited governor in 1770, and have become naturalised in the uninhabited tracts of the interior, where, however, their presence is of little importance. Seals abound on the coasts, where sea-fowls are also extremely numerous. The seals are mostly fat, and their flesh, eggs, and feathers are much sought after. Swans, and other Anatidae, frequent the lakes. The Eider Duck is plentiful on many parts of the coast, and is one of the principal articles of commerce. Fish of many kinds are abundant on the coasts, salmon and trout in the rivers. The food of the people consists in great part of fish. The cod-fishery is extensively prosecuted by the French, from two to three hundred French vessels and about 7000 seamen being employed in it, under the immediate patronage of the French government, which aims at thus training seamen for the navy. The salmon-fishery of some of the rivers has begun to be prosecuted for the supply of the London market. The herring-fishery has not hitherto received special attention, but vast shoals of herrings frequent the shores. The most important agricultural operations are those of the hay-harvest. The seeds of the Melar, or Upright Sea Lyme Grass (Elymus arenarius), are gathered and used for making potage and cakes, and are esteemed as a luxury; bread made of imported grain being seldom seen in the houses of the common people. Meal made of Iceland Middlet, v., is used in a variety of ways, and this lichen is gathered in large quantities both for home use and for exportation. Potatoes, turnips, kale and cabbage, spinach, parley, radishes, mustard, cressots, &c., are produced in gardens. The mineral wealth of I. has only begun to be developed. In no part of the world is sulphur found in such abundance. Iron ore is also found. There is a peculiar kind of brown coal called Surstrurbrand (q. v.), which, along with drift-wood, is much used for fuel on the northern and eastern coasts.

The population of I. was once 100,000, but it subsequently diminished. Since 1840, when it amounted to 37,000, it has increased gradually, until in 1855 it had reached 64,603. The people, who are of Scandinavian origin, are distinguished for honesty, purity of morals, and a wonderful love of education. Notwithstanding their poverty and other adverse circumstances, it is rare to find an Icelander who cannot read and write. They belong to the Protestant Church. The clergy are, like their parishioners, very poor; they are under one bishop. The Icelanders are not attached to their native country, and delight in the study of its history as set forth in ancient sagas and poems. Their language is the old Norwegian, preserved in almost its pristine purity. See Scandinavian Languages and Literature. They are rather a small race, and seldom attain to a great age. Scurvy is a very common disease, and cases of elephantiasis are frequent, probably owing in a great measure to the nature of their food, and still more to their miserably crowded and unventilated dwellings, which are mostly cottages of the humblest description, built of turf or of pieces of lava, the crevices stuffed with moss, and the roof formed of turf. The knitting of stockings and gloves is a common kind of domestic service. The sale of skins, wool, feathers, eider-downs, fish-oil, &c., enables the peasantry to procure a few articles of foreign produce. The chief imports are rye, barley, flour, coffee, liquors, tobacco, sugar, coal, &c. In 1835, upwards of 40,000 Danish barrels of grain (of all kinds) were imported; also about 427,000 lbs. of coffee, 1,034,000 quarts of various liquors, 109,000 lbs. of tobacco, 437,000 lbs. of sugar, and 32,000 chaldrons of coal. The annual exports are valued at 4,000,000 ryksdaler (200,000), and consist of dried fish, wool, hosiery, tallow, train-oil, lard, and preserved meat. The destruction of meadows by volcanic eruptions, and the interruption of fishing and hay-drifts, have sometimes caused great distress. Since 1855 free-trade has been in force; 32 authorised trading-places have been opened, of which Reikjavik, with a population of 13,500, and situated at the head of a bay in the south-west of the island, is the most important. Here the governor resides; the Althing (from Thang, a public assembly), a kind of parliament, is held; here are a public library of 6000 volumes, a Royal Icelandic Society, and an Observatory. 200,000 new papers, newspapers, and Icelandic books are printed. There is regular steam-communication during summer with Leith and Copenhagen.

The authentic history of I. begins in the 8th o.
ICELAND MOSS—ICHNEUMON.

When emigrants from Norway settled here. The Lendaluma Book, however, one of the earliest of the records of the island, states that the Christian relics found here by the Norwegians on their arrival— as wooden crosses, &c.—had been erected previously by Irish settlers. However this may be, it is certain that the first authentic successful settlement of I. was made under Ingolf, a Norwegian, who, after a fruitless attempt on the south coast in 870, succeeded in establishing himself at Reikjavik in 874. The changes introduced in Norway by Harald Harenger caused many who could not endure them to betake themselves to other countries, and particularly to I., all the habitable coast districts of which were occupied within sixty years, and the old Norwegian institutions were transferred to it unmodified. The government was at first, in the times of paganus, hierarchic and aristocratic; it became afterwards a kind of aristocratic republic. The Althing met every summer in the valley of Thingvalla. Christianity was not established by law till 1000 A.D., and then not without much opposition. Schools were then founded, and the bishops appointed in 1070 and Skalholt.

The Icelanders were enterprising sailors in the early periods of their history, and discovered Greenland about the year 992, and a part of the American continent called Findland, about 986. They made voyages also to the south, visiting the furthest parts of the Mediterranean. The most flourishing period of Iceland literature and commerce was from the middle of the 12th to the beginning of the 13th c., when, in consequence of domestic broils, Haco VI. of Norway succeeded in reducing the whole island under his sway, and a declension began, which continued till a new impulse was given to the minds of men, here as elsewhere, by the Reformation. When invited to Denmark in 1350, I. shared its fate, but was not transferred along with Norway to a new allegiance in 1814. The Protestant religion was introduced in 1540, but not fully established till 1551. In the 17th c., the island suffered much from the ravages of Algerine pirates, who carried away many persons to slavery. In 1707, small-boat carried off 18,000 persons; and in 1784—1785, about 9000 died of famine. Famine was again very severe in 1824 and 1825, and was followed by a fatal epidemic in 1827. The Althing, after it had subsisted for fully 900 years, was suppressed in the beginning of the 19th c., but was reorganised on a somewhat different model in 1843.—See Von Troll, Letters on Iceland, 1772; Sir George Mackenzie, Travels in Iceland, 1810 (cheap edition by W. and R. Chambers, 1851); Henderson, Journal of a Residence in Iceland, 1818; R. Chambers, Travels in Iceland and the Faroe Islands, 1826; G. S. Forbes, Iceland, its Volcanoes, Geysers, and glaciers, 1800.

ICELAND MOSS (Cetraria Islandica), a lichen found in all the northern parts of the world, and valuable on account of its nutritious and medicinal properties. It is collected as an article of commerce in Norway and Iceland. In very northern regions, it grows even near the level of the sea; in more southern countries, it is found on mountains. It is not uncommon in the mountainous parts of Britain, although not turned to any economic account. In Carniola, it is used for fattening cattle and pigs. It grows in extreme abundance in Iceland on tracts otherwise desert; and numerous parties migrate from great distances with horses, tents, and provisions, in the summer months, for the sole purpose of gathering it, as an article of commerce, and for food. In many places, this lichen thickly covers the whole surface of the ground, growing about 1—4 inches high; and consisting of an almost erect Thallus (q. v.). It is of a leathery and somewhat cartilaginous substance. When I. M. is used as an article of food, its bitterness is first partially removed by steeping in water, after which, in Iceland and other northern countries, it is sometimes pounded and made into bread; or it is prepared by boiling, the first water being rejected. It is often boiled with milk, making a kind of jelly, either with milk or water. It is an agreeable article of food, and very suitable for invalids. It contains about 80 per cent. of a kind of starch called Lichen Starch, or Lichenin, and owes its bitterness to an acid principle, Cetraria Acid.—An allied species, Cetraria nivalis, growing in northern countries, possesses similar properties. It is very abundant in some parts of Iceland, it is much used for food, and is called Mary's Gravy by the Icelanders.

ICHNEUMON (Herpestes), a genus of diptere carnivorous quadrupeds of the family Herpestidae (q. v.), having a much elongated body, small head, sharp muzzle, rounded ears, and short legs. The species, which are pretty numerous, are natives of Africa and the warmer parts of Asia. One, the ANDALUSIAN I. (H. Widlestringtonii), occurs in the south of Spain. They feed on small quadrupeds, reptiles, eggs, and insects. Some of them, particularly the EGYPTIAN I. (H. ichneumon) and the MANGUOTE or MUNGO (H. griesii) of India, have been greatly celebrated as destroyers of serpents and other noxious reptiles, many wonderful fables being superadded to the truth on this subject. The Egyptian I., the I. of the ancients, is larger than a cat, gray, with black paws and muzzle, and a black tuft of diverging hairs at the end of the tail. It abounds in Lower Egypt, but in Upper Egypt it is comparatively rare. It often enters houses, and devours poultry and their eggs. With noiseless gliding motion it advances on serpents until it can suddenly
ICHNEUMON.—ICHNOLOGY.

... seize them behind the head, where its long sharp teeth inflict a fatal wound. It scratches up the sand beneath the creature which it eats with great avidity. It was a sacred animal to the ancient Egyptians; the killing of it was forbidden; and individuals, for the maintenance of which funds were set apart, were objects of worship. The I. is easily domesticated, and forms a cat-like attachment to the place of its residence. It is useful in keeping houses free of rats and other vermin. It is therefore not unfrequently domesticated in the houses of the magusante also is in India. This species is rather smaller, of a lighter colour, and has a pointed tail.

ICHNEUMON, a Linnæan genus of insects, now constituting a family or tribe, Ichnemonidae, of the order Hymenoptera, section Tereteants. The Ichnemonidae are extremely numerous, Gravenhorst's Ichnomonologia Europaea describes nearly 1650 European species, and they are equally abundant in other parts of the world. Many of them are minute, others are large insects; a few of the tropical species are amongst the largest of insects. They have the abdomen united to the thorax by a pedicle, which is often very slender. The abdomen itself is slender, and the whole form attenuated. The antennae are generally thread-like, composed of a great number of joints, and are kept in very constant vibration. The ovipositor in some is short; in some it is very long, much longer than the body of the insect, and enclosed in a kind of sheath formed of two parts, concave on their inner surface, from which it is disengaged when about to be used, the whole form often seeming as three threads proceeding from the extremity of the abdomen. All the Ichnemonidae deposit their eggs either in or on—generally in—the bodies, eggs, or larvae of insects, or in spiders. Some of them deposit their eggs in sponges. They are thus extremely useful to the farmer and gardener. Particular species of Ichnemonidae are the natural enemies of particular kinds of other insects. Thus, Microceraster glomeratus and Pimphila instigator lay their eggs in the catterpillars of the cabbage butterfly. Some species deposit only one egg in the egg or larva which is destined to afford food to their own larva; others deposit a number of eggs together. Those which have a long ovipositor usually deposit eggs in the bark of trees, in holes of wood, &c. The I. larva generally consume only the fat of the larva on which they feed, which continues to subsist and so sustains them till they are ready for transformation into pupae. In their perfect state, the Ichnemonidae feed only on the juices of flowers. They are very often to be seen flying about umbelliferous flowers. The I. larvae are without feet. The pupae of many are enclosed in silken cocoons.

ICHNOLOGY (Gr. science of footprints) is the name given to that section of Palæontology which treats of the impressions made on mud or sand, now incrustated into rock, by the animals of the period to which the rocks belong, or by meteoric or other tertiary physical forces. The actual remains of the hard portions of the animals themselves are the materials on which chiefly rests our knowledge of the former inhabitants of the globe; but of many animals we know nothing more than the more or less distinct impressions made by them as they moved over the surface of a muddy shore, or the sudden and heavy thunder-shower, has left its impress upon them, and this so perfectly, that it is not difficult to determine, from the form of the cup-like depression, whether or not the rain was accompanied by a breeze, or, by observing the amount of difference in the sides of the cup, and the position of the highest part, the direction of the gale and its velocity may be approximately determined. Though the force or body forming the impression has been removed immediately after it has made the pressure, yet in these prints the evidences of animal life and of the activity of physical forces, have come down to us from the remotest periods.

The impressions occur almost invariably on rocks that have been deposited as mud; only in a few cases have they been noticed in sandstone. Sometimes the argillaceous deposit is a thin layer between two sandstone beds; it is then difficult to obtain a clear surface in the shale; but the details are carefully preserved in relief in the natural cast on the under surface of the superimposed sandstone. In this manner the footprints are preserved at Sturton in Cheshire.

The necessary conditions for the preservation of footprints seem to be either of the following. The silt-bed may have formed an extensive flat shore, uncovered by the tide at each ebbing. Whatever impressions were made on this plastic surface would be laked and preserved by the influence of the sun, if it remained for a sufficient time uncovered by the water; and when the tide again flowed, the hardened mud, resisting its influence, would receive another film of sediment, which would specially deposit itself in the depressions, and thus secure the permanence of the impressions. These influences would operate more powerfully on portions of the shore which were under water only at spring-tides. The impressions of numerous wading birds are preserved in this manner, on the plastic mud which covers the flat shore of the Bay of Fundy, where the tide rises, it is said, as much as 70 feet. Both Gould and Lyell have given detailed accounts of the process as it goes on there. The other method is one independent of the sun's influence, where, on an ordinary muddy shore during the recession of the tide, the depressions are filled up by blown sand, and the tide, on its return, flows over a level surface, on which it deposits a fresh layer of silt.

The study of ichnology carries us back to the remotest known period of animal life on the globe. The deposit from which has been obtained the fragment of trilobite (Palaieopgy) which contains the borings of certain worms (fig. 1) and impressions of min-drops. In strata of the same period, but a little later, series of regularly recurring groups of markings are considered by Mr Salter as having been produced by the sharp claws of crustaceans in walking; while other sets he refers, with considerable show of probability, to the strokes of the bifurcate tail of an unknown crustacean as it swam through shallow water. From the American representatives of the same rocks (Potsdam sandstones), Professor Owen has described a number of peculiar animals, to which he has given the generic name of Protichnites. The slabs shew that the animals...
made at each step 14, 16, or more impressions. They were most probably crustaceae, furnished with three or four pairs of bifurcatecr limbs, like the modern king-cray. Similar impressions have been observed in the Lower Silurian rocks of Eskdale in Scotland, and have been named _P. Scotius_. The tracks of numerous annelida occur also in these rocks. They of animals passing together across a tide-reefed estuary, to some frequented ground periodically sought for food or pleasure. No animal remains whatever have been found associated with them; they seem, however, to belong to forms of tortoise. The slab figured is a portion of the track probably of a long-tailed Chelonian, with a stride a little over six inches. The pad of the foot was soft and smooth; the light impressions of the fore-foot were nearly obliterated by the hind-foot, which was furnished with four claws (fig. 3). Sir William Jardine, on whose property the Corincockle quarries are, has made these tracks the subject of a valuable and elaborate monograph.

In the Triassic rocks, the well-known foot-tracks of the Labyrinthodon (q. v.) occur. The earliest evidence of the existence of birds are the traces of their feet in the argillaceous sandstones of Connecticut, which are now known to be of the Lower Oolitic age. The structure of the tridactyl feet which produced these impressions exhibits the regular progression in the number of the toe-joints from the innermost to the outermost, peculiar to birds, and they must be taken as evidencing the occurrence thus early of the class, although a considerable interval elapsed before the first true fossil of a bird occurs; namely, the remarkable long-tailed bird from the Upper Oolite rocks of Solenhofen, recently described by Professor Owen. Immense tridactyl footprints have been known for many years in rocks of Wealden age in the south-east of England. At first, they were supposed to be bird's; but a more careful examination has shown them to belong to reptiles; and the discovery in the same strata of the perfect foot of a young iguanodon, measuring 21 inches in length, furnished with three toes, which would form a print precisely similar to the tracks so long known, shows them to have been certainly produced by the Iguanodon (q. v.).

**ICHNODYORDORULITE** (Gr. fish-spear-stone), the name given to fossil fish spines, that are not uncommon in the stratified rocks. Plagiostome fishes have their dorsal fin furnished in front with a strong bony spine. The fin is connected with the spine, and is elevated and depressed by its movement. It seems also to be employed by the fish as a defence against its larger foes. Some bony fishes have similar spines, as the Sticklebacks, Sihurids, &c. The spines are most frequently unassociated with any fish remains, having belonged to plagiostome fish, in which the spine is simply imbedded in the flesh, and consequently would be speedily separated from the body of the fish when it began to decompose. The earliest certain evidence of vertebrate animals is the spines of plagiostomous cartilaginous fishes which occur in the bone bed of the Ludlow rocks, the uppermost of the Silurian deposits. Spines belonging apparently to three species have been found; they are small, compressed, slightly curved

---

**Fig. 2.** _Nereites Cambrensis._
*From the Lower Silurian Shales of Moffat.*

The footprints of a small reptile had been observed on the sandstone of a quarry near Elgin, which most probably belongs to the Old Red Sandstone Measures. In 1851, it was discovered that they were produced by a little reptile (Telerpeton Elginense), whose remains were there found. And lately, Professor Huxley has referred a different set of impressions to his lately described remarkable fish-like reptile, Stagonolepis.

The Coal Measures of our own country and of Germany have disclosed the footprints of different reptiles.

The New Red Sandstone strata abound in footprints. It was the Permian or lower division of this series that supplied, in 1828, the impressions which gave the first indication of animal life from such evidences to the mind of Dr. Duncan—a man who deserves to be remembered less for his works in natural history, important though they were, than for his eminent services to his country as the founder of savings-banks. The tracks he described occur on the layers of unctuous clay which separate the beds of sandstone in the quarries at Corincockle, Dumfriesshire; they frequently are clear and delicate, as at the moment when they were impressed, and

**Fig. 3.** Footprints of a Tortoise.

are repeated bed after bed on the fresh tablets as they were prepared for their reception. From their number and direction, they seem to be the tracks

---

**Fig. 4.** Footprints of Birds.
*On the Oolitic Sandstones of Connecticut.*
and finely grooved lengthwise, and belong to the genus Onchias. Along with them have been found petrified portions of tubercular and prickly skin, like the shagreen of the shark.

The Old Red Sandstone has supplied such a variety of spines as to have afforded the materials for establishing fourteen genera, and in the Coal Measures they are more numerous, belonging to no less than twenty-one genera.

**ICHTHYOLOGY** (Gr. ichthys, a fish; logos, a discourse), that branch of natural history which treats of fishes. Aristotle is the most ancient author having any claim to be noticed in a history of ichthyology, nor was this science much indebted to any other of the ancients. In modern times, it began to be cultivated, about the middle of the 16th c., by Belon, Rondelet, and Salviani. Towards the close of the 17th c., it made great progress through the labours of Willoughby and Ray; in the 18th c., through those of Artedi, Klein, Linnae, Gronow, Brunich, Scopoli, and Bloch; in the beginning of the 19th c., through those of Cuvier and Del Cépédé; whilst, more recently, Valenciennes, Müller, Agassiz, and Owen are eminent amongst many who have prosecuted the study of ichthyology with ardour and success. The name of Yarrell deserves to be particularly mentioned for his work on British Fishes. The earlier ichthyologists generally included the Cetacea among fishes. Linné removed the Cetacea to their proper place. He also placed the Cartilaginous Fishes with Reptiles in his class Amphibia, from which they have since been, by the common consent of naturalists, brought back to their place in the class of Fishes. Linné's system of ichthyology is almost as artificial as his system of botany. It is founded on the relative positions of the pectoral and ventral fins, without reference to any important point of comparative anatomy or animal economy. Other ichthyologists, both before and since, have laboured to discover a natural arrangement, to which the progress of comparative anatomy has greatly contributed, although success is still confessedly very imperfect. Even the system of Agassiz, founded on the external covering of fishes, is not wholly artificial, and is of very convenient application to fossil ichthyology.

**ICHTHYOSAURUS** (Gr. fish-reptile), a remarkable genus of reptiles which inhabited the sea during the deposition of the Secondary strata. Like the modern Cetacea, their structure was modified to suit their aquatic life. The body was shaped like that of a fish, the limbs were developed into paddles, and the tail, long and lizard-like, was furnished, it is believed, with a fleshly fin, as in the dolphin, except that its position was vertical. The head was large, and produced into a long and pointed snout, resembling that of the crocodile, except that the orbit was much larger, and had the nostril placed close to it, as in the whale, and not near the end of the snout. The jaws were furnished with a large series of powerful conical teeth, lodged close together in a continuous groove, in which the divisions for sockets, which exist in the crocodile, were indicated by the vertical ridges on the maxillary bone.

The teeth were hollow at the root, sheathing the young teeth, which gradually absorbed the base of the older ones, and, as they grew, pressed them forward, until they finally displaced them. The long and slender jaws were strengthened to resist any sudden shock by being formed of many thin bony plates, which produced light and elastic as well as strong jaws. The most remarkable feature in the head was the eye, which was not only very large—in some specimens measuring 13 inches in diameter—but was specially fitted to accommodate itself for vision in air or water, as well as for speedily altering the focal distance while pursuing its prey. The structure, which thus fitted the eye so remarkably to the wants of the animal, consists of a circle of 13 or more overlapping sclerotic bony plates surrounding the pupil, as in birds. This circle acted as a sort of self-adjusting telescope, and accompanied by the extraordinary amount of light admitted by the large pupil, enabled the ichthyosaur to discover its prey at great or little distances in the obscurity of the night, and in the depths of the sea. The neck was so short that the body was probably not in the least constricted behind the head. The backbone, was fish-like; each joint had both its surfaces hollow, making the whole column very flexible. The small size of the paddles compared with the body, and the stiffness of the short neck, seem to suggest that the tail must have been an important organ of motion.

Professor Owen is satisfied that it was furnished with a vertical tail, because the vertebrae are compressed vertically, and also because the tail is frequently found disarticulated a short distance from its extremity, as if the weight of the upright tail had caused it to fall when the animal had begun to decompose. The fish-like body, the four paddles, and especially the powerful tail, would make the ichthyosaur active in their movements; and consequently, with their predaceous habits, very dangerous enemies to the other animals that inhabited with them the Secondary seas. That their principal food consisted of fishes, is evident from the masses of broken bones and scales of contemporary fishes that have been found under their ribs in the place where the stomach of the animal was situated.

The remains of ichthyosauri are peculiar to the Secondary strata, occurring in the various members of the series from the Lower Lias to the Chalk, but having their greatest development in the Lias and Oolite. More than 30 species have been discovered; they differ from each other chiefly in the form of the head, some having a long and slender snout, like the gavial of the Ganges, while others had short and broad heads, more like the common crocodile. The great repository for ichthyosaurian remains hitherto has been the Lias at Lyme Regis.

**ICHTHYOSIS, or FISH-SKIN DISEASE,** is characterized by a hardened, thickened, rough, and almost horny state of the cuticle, which breaks...
into small, irregular, scale-like pieces, which do not readily exfoliate, but which, if removed, are speedily reproduced. The disease may affect almost the whole surface, or may be confined to a single part; and is most frequent, but not always, congenital. It is attended with no constitutional disturbance, and the general health is often very good. The disease is, however, extremely obstinate, and when congenital, may be considered as incurable.

The treatment consists in the frequent use of the warm or vapour bath, so as to soften the thickened epidermis and to facilitate its removal, and friction by means of a piece of flannel may be conjoined with the bath. The employment of sulphuraceous baths, such as those at Harrogate, has occasionally been found of temporary use; and the internal administration of tar, cod-liver oil, &c., sometimes gives relief.

ICICLES, in heraldry, are charges of the same shape as drops in the bearing called Gutté (q. v.), but reversed. They have also been called Clubs, Locks of Hair, and Guttés reversed.

ICILIUS, the name of a plebeian family in Rome, which produced some of the most zealous defenders of the plebeian interest against the patricians. The name of one of them is associated with one of the most momentous incidents in the legendary history of Rome. See APPIUS CLAUDIUS.

ICO'D, or ICD DE LOS VINOS, a small town on the north-west coast of Tenerife, one of the Canaries (q. v.). Pop. upwards of 5000.

ICOLKILL. See IONA.

ICONIUM. See KONIHZ.

ICONOCLASTS (Gr. ἐκον, image, and κλάω, I break), the name used to designate those in the church from the 8th c. onwards, who had been opposed to the use of sacred images; that is, of statues, pictures, and other sensible representations of sacred objects; or at least to the paying of religious honour or reverence to such representations. The iconoclast movement had its commencement in the Eastern Church. Opinion is divided as to the origin and antiquity of the practice of Image-worship (q. v.) in the church; but it is certain that in the 6th and 7th centuries it prevailed extensively, especially in the Eastern Empire, and that practices existed in some churches which were a source of much suspicion, and even of positive offence. Many bishops interposed to correct these abuses; but the iconoclast movement, strictly so called, began with the imperial edict issued in 726 by the Emperor Leo III., surnamed the Isaurian, forbidding the honours paid to sacred images, and even commanding the removal from the churches of all images, that of our Lord alone excepted. This was followed by another decree in 730, which prohibited, under pain of death, as sinful and idolatrous, all acts of reverence, public or private, to images, and directed that, wherever such images should be found, they should forthwith be removed or destroyed. The attempt to enforce this decree occasioned great agitation, especially in the Greek islands and in Italy. The popes Gregory II. and Gregory III. protested vehemently against it, repudiated the imputation of idolatry, and explained the nature of the honours to images for which they contended. Leo persevered, nevertheless, in his opposition, which was continued by his successor, Constantine, surnamed Copronymus. Under this emperor, a council was held in Constantinople in 754, in which the iconoclast decrees were affirmed in their fullest extent; and Constantine's son, Leo IV., renewed, on his accession in 773, the enactments of his predecessors. Under the widow of Leo, the Empress Irene, a council was held at Nice, 786, (see IMAGOEWORSHIP), in which these proceedings were condemned and revoked; but other succeeding emperors, Nicephorus (802—811), Leo the Armenian (813—820), Michael the Stammerer, and Theophilius, returned, with greater or less severity, to the policy of the iconoclast emperors. As regards the Greek Church, the controversy may be said to have been finally settled under the Em- press Theodora in a council held at Constantinople in 840, or at least by a subsequent one of 870. The modern usage of the Greek Church permits pictures, but rejects graven or sculptured representations of sacred objects. Except in Italy, the iconoclast controversy created but little sensation in the Western Church until the movement in the time of Charlemagne and his successors, which shall be noticed under IMAGE-WORSHIP.

In the modern church, the popular violence directed in Switzerland, Great Britain, and some parts of Germany, against crucifixes, images of saints, and other objects associated with what has been stigmatised as the idolatry of Rome, have sometimes been described under the name of Iconoclasm.

ICY CAPE, a headland of Russian America, is in the 71st degree of north latitude, about the middle of that long reach of the arctic coast between Cape Lisburne on the south-west, and Cape North or Point Barrow on the north-east. It was discovered by Cook in 1778, and was his furthest point north of Behring's Strait.

IDA, a high mountain range, in Asia Minor, extending from Phrygia through Mysia into Thrace. The city of Troy was situated at its base. It is the scene of many ancient legends. The southern part of the range was called Carian; the highest peak of which is about 4700 feet above the sea. Here there was a temple of Cybele, which therefore was called the Idaen Mother. From Ida flow several famous streams, as the Graecus, Simois, and Scamander. There is another Ida in Crete, extending from west to east, and now called Psiloriti. On this Ida, according to an ancient legend, Zeus was educated.

IDE (Leuciscus idus), a fish of the family Cyprinidae, of the same genus with the roach, dan, &c. It is a native of the lakes of the northern parts of Europe, ascending rivers in April and May to spawn. The ide is one of those fishes which it seems both easy and desirable to introduce into British waters.

IDEA. This word has borne very distinct meanings in the history of philosophy. Down to the 17th c., it had the signification given to it by Plato, and referred to the Platonic doctrine of eternal forms existing in the Divine mind, according to which the world and all sensible things were framed. Plato made a grand distinction between
the illegible, or what occupied the intellect, and the sensible; the one represented the eternal, the immutable, and the certain; the other, the mutable and fleeting part of the universe. The forms proceeded from matter; the actual circles occurring in nature were produced original foreshadowing idea circle holding a place in the Divine intelligence; the actual men were generated from an ideal man. The word was used in this sense in literature as well as in philosophy down to the 17th c., as in Spenser, Shakespeare, Hooker, and Milton. Thus in Paradise Lost—

"God saw his works were good, Answering his fair idea."

Sir W. Hamilton dates the change that came over the application of the word from the publication of Descartes's Discours on Method in 1637, remarking, however, that in a treatise by David Buchanan, published at Paris the same year, the new meaning had been introduced. "The fortune of this word is curious. Employed by Plato to express the real forms of the intelligible world, in lofty contrast to the mere accidents of the sensible world, an angel, it was relegated from the sphere of Divine intelligence to the atmosphere of human sense; till at last Ideologie (more correctly Ideologia), a word which could only properly suggest an a priori science, the use of our knowledge, the word has in France become the name peculiarly distinctive of that philosophy of mind which exclusively derives our knowledge from the senses."—Hamilton's Discussions, p. 70.

In speaking of the mental representation of external things, Descartes, instead of employing the various terms image, species, phantasm, &c., which had been the words formerly in use for that particular signification, used the word idea. In this he was followed by other philosophers, as, for example, Locke, who states that he has adopted the word to stand for 'whatever is the object of the understanding, when a man thinks.' Thus the mental impression that we are supposed to have when thinking of the sun, without seeing the actual object, is called our idea of the sun. The idea is thus in contrast with the sensation, or the feeling that we have when the senses are engaged directly or immediately upon the thing itself. The sensation is what constitutes the thing, the reality: the impression persisting after the thing has gone, and recoverable by mental causes without the original, is the idea. Although the word in this application may be so guarded as to lead to no bad consequences, Dr Reid was of opinion that it gave countenance to the setting up of a new and fictitious element in the operations of the mind. This, however, raises the great question of metaphysics—of the formal nature of our knowledge of an external world. See Perception.

It is difficult to avoid the use of the word idea, and yet, owing to the looseness of its application, there is a danger of its not conveying a definite signification, leading to such a misapprehension of the contrast to sensation, or to actuality; and no better term has yet been found than idea, being what is common to memory and to imagination, and expressing the mind as not under the present impression of real objects but as, by its own facility and associating powers, having those objects to all practical ends before its view. Thus, all our sensations, whether of sight, hearing, touch, taste, or smell, and all the feelings that we have in the exercise of our moving energies, become transformed into ideas when, without the real presence of the original agency, we can deal with them in the way of pursuit or avoidance, or can discriminate and compare them, nearly as if in their first condition as sensation. Sir W. Hamilton, in his Lectures on Logic (i. 126), has endeavoured to avoid employing the word, but other writers on mental philosophy have freely adopted it in the above acceptance. See also Generalisation and Imagination.

IDEKER, CHRISTIAN LUDWIG, an eminent astronomer and mathematician, was born 21st September 1766, at Gross-see near Perleberg in Prussia, and, after holding various offices, received a professorship at the university of Berlin in 1821. He died August 10, 1846. His most important works are: Historische Untersuchungen über die Astronomischen Beobachtungen der Alten (Leip., 1806); Untersuchung über den Ursprung und die Bedeutung der Sternnamen (Berlin, 1809); Handbuch der Mathematischen und Technischen Chronologie (2 vols. Berlin, 1825—1826), the last of which work he had presented a clear view of the reckoning of time among the ancients; and Die Zeitrechnung der Chinesen (Berlin, 1839).

ITEM, SONANS, a term sometimes used in English law, where a mistake as to a surname is made in a legal document, to denote that the name so used by mistake was of a similar sound, in which case the mistake is generally treated as immaterial.

IDENTITY of person in point of law must often be proved in legal proceedings, as in proving a marriage, proving a pedigree, proving a theft, &c. The usual proof is the oath of some one who knew who or was cognizant of the facts at both the times referred to. A favourite defence of thieves and persons accused of crime is, that it is a case of mistaken identity, in which case the prisoner must generally establish an alibi—i.e., that he was in some other place at the time in question.

IDENTITY, CONTRADICTION, AND EXCLUDED MIDDLE. It has been common to look upon some truths as necessary, in opposition to others that, although certain in all intents and purposes, are not necessary, but contingent. Thus, it is considered a necessary truth, that two straight lines cannot enclose a space; that the less cannot include the greater; that a man cannot be in two places at the same time. On the other hand, it is not necessary that gold should be yellow, or water transparent; those facts, we conceive, might have been otherwise arranged. There has been much controversy as to this character of necessity that distinguishes some of our beliefs from others. See Necessity. The schoolmen laid down three principles, involving what they considered the widest generalisations of our necessary beliefs: these are the laws of Identity, Contradiction, and Excluded Middle.

The law of Identity is expressed thus: 'Whatever is, is; is, is; a proposition justly considered as irresistible. If any objection lies against it, it is, that nothing appears to be got by affirming it. When we say that 'Water freezes at 32°,' there is a piece of new information conveyed; by merely knowing water in its liquid state, we should not know that at 32° it became solid; the affirmation is something real. But when we say that 'Water is water,' there is the form of information, but nothing is conveyed; the proposition belongs to the class termed 'identical.' We merely re-affirm what is already affirmed. The law of identity can only mean that we are to adhere to the meaning of a word as once given; that is to say, we should be consistent
IDENTITY, CONTRADICTION, AND EXCLUDED MIDDLE.

in the use of terms. It is a law, not of things, but of the employment of language to denote things.

The law of Contraction is, that 'the same attribute cannot be both affirmed and negated of the same subject;' or that a thing cannot be and not be at the same time. In other words, two affirmations that contradict each other cannot be both true. We cannot say both that the Sun has risen, and the 'Sun has not risen:' 'Gold is heavy,' and 'Gold is not heavy.' Here, also, one might suggest the remark, that the proposition is an identical one; for the use of the word 'not' can only mean that the proposition to which it is coupled cannot be held along with the proposition to which it is not coupled. That if the affirmative be true the negative must be false, and if the negative be true the affirmative must be false, are but the same thing differently expressed. The word 'not' is an abbreviation for what would otherwise be a more roundabout expression. Instead of saying: 'I disbelieve, and deny that gold is white,' we say: 'Gold is not white.' So far, therefore, the principle of contraction, like that of identity, is not a law of things, but of the use of language; implying simply, that when we have affirmed a fact in one form of words, we must, in varying its terms, adhere to the same principle.

But this remark does not exhaust the scope of the principle. It has already been observed (see CONDITIONED), that our knowledge can never be confined to one absolute property; in other words, to one concept. We must know something different from it. We cannot even be conscious of one unvarying impression; animals that live in total darkness are not conscious of the darkness, they would become so only in passing into light. It is true, however, of concepts in the habit of mentioning a single property, and leaving out of account the related fact but for which the first would have no existence; we may talk of light without alluding to darkness. But it is not the less certain that the alternative, circumstance, for the time suppressed, is a real part of the case; and there are many occasions, when our meaning cannot be fully imparted without actually quoting the alternative; and to be logically or formally complete, we ought at all times to state the two.

There are many qualities the very mention of which brings vividly before the mind an opposed couple: as, up, down; straight, crooked; desire, aversion; &c. But beyond these cases, it is a tenable assertion that every fact or property recognised by the human mind must be recognised with relation to some other fact or property, its contrast or opposite, but for which as an alternative, the mind would not have that opportunity of transition essential to consciousness itself. Take redness, which does not suggest to the mind an opposite in the same manifest form as in the above instances. If all light were red, there would be no designation of redness; the only terms would be light and dark. But as there are varieties of light, that is, as we experience mental shocks or impressions by transitions occurring under the luminous agency, we are made aware to subordinate distinctive differences, which we mark as so many distinct properties. When white and red are presented to the eye in succession, there is imparted a shock of difference, developing an item of knowledge, which, to be fully expressed, would be 'white-red.' White would then be the maximum of red, and red the opposite of white; to the affirmation, 'Snow is white,' there would correspond as an essential and inseparable part of the same fact, 'Snow is not red.' But as there are a great many transitions of colour that make the mind sensible to difference, the mention of one colour is attended with, not one simple denial, but many denials. We have red-green, red-yellow, red-blue, &c.; and, moreover, when these couples pass in succession, we are either struck with some fact of agreement in the common effect 'redness.' Thus, the fact or property, 'redness,' is the name for the common element in certain couples, which numerical inflation is in each case the contrasting element; it is not-white, not-green, not-yellow, not-blue, and not every other colour, which placed side by side with it made the mind alive to difference. When, by differences and agreements as now described, a class of colours is constituted, the mention of one is the denial of every other member of the class; and the denial of one is the mention of some other or others, provided we are keeping our attention confined to that class. Professor de Morga has introduced into logic the phrase 'universe of the proposition,' to intimate the class of objects implied when an affirmation, with its corresponding denial, is given forth. Thus, 'Such a thing is red,' implies as the universe of the proposition the class of colours; 'A rose smells sweet' is in the universe 'odours.'

Many other examples might be quoted in illustration of the general principle, and also to shew the operation of ambiguity or unities. The meaning of a positive term, the proper remedy is to demand an explicit statement of the quality, or qualities, denied. Thus, if a thing is spoken of as 'beautiful,' which contrast is intended? for there is 'beautiful, not ugly or deformed,' 'not indifferent or insipid,' 'not sublime?' &c. The important function of defining terms is thus, in the last resort, to bring into open statement, what is usually left in the form of a principle or rule of opposition corresponding to each affirmation. See also CONDITIONED.

The principle of Excluded Middle is another form of the principle of Contraction, implying the same general fact, and resting on the same foundations. It is, that of two contrarieties, both cannot be false, or one must be true. Any given assertion must be either true or false; either the affirmative is true, or otherwise the negative is true, which is expressed in the formal expression of the principle as the principle of contraction; for the attribute affirmed or denied must be something intelligible and definite, as well as relevant to the subject in hand. We often say such a thing is neither big nor little, implying that there is a certain mean point that excludes the extremes, and yet those two terms are the negative of each other. In a word, it is an essential condition of the principle that the universe of the proposition should be distinctly understood and kept in view. If we say 'this is either red or not red,' the alternative is indisputable within the universe 'colour,' but not otherwise; the taste of an orange is neither red nor not red: if we jump over the impossibilities of the class, the principle no longer holds good.

The three principles of Identity, Contradiction, and Excluded Middle, are usually talked of as necessities of the human mind, from which there is no escape. But we have just shewn that in the case of the Excluded Middle, there are possible evasions; and even the principle of contradiction itself is flatly met by Hegel, who lays it down as a maxim of his philosophy that 'being' and 'not being' are the same, and deduces important results from it. All this should make us cautious in declaring
may form a. any doctrine to be absolutely necessary, or imperative on the human mind.

IDES. See Calends.

IDIOCY is the non-development of the mental faculties. A dement is deprived of powers which he once possessed; an idiot never ex-

cessively, possesses such powers. In certain cases, the human form appears scarcely to be animated by intelligence at all; it is a senseless, motionless mass, to which the special senses impart no intuition of art and virtue, and from which there are no manifestations of human love or passion, or perception. The degrees of depravation are, however, very numerous and sharply defined, so as to suggest different modes of management and training, and different degrees of moral or presentable heads in the individuals. The general characteristics of the vast majority of idiots may be held to be diminutive stature, grotesque appearance, inactivity, uncanny behaviour, gluttony, obtuse or acute sensibility, inability to regulate movements, to articulate, to express degradation of propensities, and helplessness. The various degrees of their dependence upon others has been estimated thus: of 574—53 were as helpless as infants; 74 as children of two years old; 94 as children of seven years old; 128 could engage in simple work with some small profit, if care fully watched and directed; 179 could nearly earn their bread; and 36 could, under due discipline, maintain themselves. In this calculation, imbueus is included. The arrestment of the evolution of intelligence, in whole or in part, may commence and be consummated previous to birth, in consequence of moral impressions or accidents or disease on the part of the mother; during infancy; during childhood up to puberty, from scrofula, rickets, hydrocephalus, and from unwise interference with the faculties in process of growth. A large number of individuals are microcephalous, or present heads of very small dimensions; and though they decay and die at an early age, they are apparently healthy. But a much larger number are not merely examples of imperfect growth, but are labour under positive diseases of degeneration, and present symptoms either of constitutional taint, or of those specific affections, such as convulsions and paralysis, as are referred to the nervous structure.

The abominations which occasionally take place under judicious treatment, and the eductability of a few individuals within a certain range, have suggested to physicians and philanthropists the propriety of attempting to re-educate, direct, and apply such powers as may exist. The experiment has not yet been fully carried out, but a magnificent training institution has been in operation for several years at Earlewood, Reigate; a smaller well-conducted school exists at Baldovan, in Forfarshire; and another, which is intended, and deserves to be a national establishment for Scotland, is now erecting at Larbert—Seguin, Traitement Moral, &c., des Idiots ; Art. 'Idiotisme,' Dict. de Medicine; Abbob, Handbook of Idiocy; Buchan, Brown, Treatment and Cures of Creains and Idiots.

IDIOSYNCRASY (Gr., a peculiar tempera-
ture), the name given to any constitutional pecul-

arity. Thus, there are persons who have a great dislike to particular kinds of food, smells, sounds, &c., which to most persons are agreeable; and, on the other hand, some are specially affectec-
ted for things generally disliked. In particular individuals, again, an eruption of the skin will be caused by eating strawberries, or sowing by the smell of a rose, and that quite unconnected with any liking or disliking; and such effects are pro-

duced when the person is unaware of the cause. Idiosyncrasies also occur, in consequence of which certain medicines become inoperative, or certain poisons harmless. Idiosynhrasies are either permanent or temporary, sometimes arising from mere morbid conditions, and disappearing along with them. The term is also employed to denote mental, as well as physical peculiarities.

IDOCRASE. See VENUSIAN.

IDOL (Gr. eido/kein, an image), IDOLATRY (worship [latrieia] of images). By the name idol is meant an image intended to represent a divine, or to be adored as such. The act of worshipping such an object as a divinity is called idolatry. Although the first principles of reason suggest to man's mind the idea of one Supreme Being, the source of all existing things, and the origin of all good (see God), yet the very earliest historical records, sacred and profane, teem with evidences of the errors into which men quickly fell through ignorance and passion, changing 'the glory of the incorruptible God into an image made like to corruptible man, and to birds, and four-footed beasts, and creeping things' (Rom. i. 23). To these images, as well as to the images of inanimate objects, or of the ideal powers or forces supposed to be embodied in such objects; as the moon, the sun, the moon, the moon, and four-footed beasts, and creeping things' (Rom. i. 23). To these images, as well as to the images of inanimate objects, or of the ideal powers or forces supposed to be embodied in such objects; as the moon, the sun, the moon, the moon, and four-footed beasts, and creeping things, and other natural elements—divine honours were paid by most of the ancient nations; to which honours the name of idolatry has been given. Hence, in each case of the use of the term idol it is implied that certain peculiar symbols, the idolatry of the ancient Gentile religions may be reduced to four classes: 1. The idolatry of nature-worship, which was of two kinds—the first of inorganic nature, which consisted chiefly in Lithus, or the usual appearance of pillars, mentioned in Leviticus, xxvi., and in Numbers, xxxiii. 52; the second of organic nature, or of the powers of nature, as Deadroldati, or the worship of trees—under which form were symbolised the productive or generative powers of nature, and to which the most modern investigators of Phoenician antiquities trace the origin, as well of the grossly unnatural worship of the Ashartoth of the Phoenicians, as of the phallic worship, which found its way, under various forms, through all the nations of the Egyptians, as in that of the still more degrading forms of animal life which constituted the object of adoration with other nations. 3. A higher form of idolatry, which prevailed among the races of Chaldean origin, was Astrolatri, or star-worship, which is often designated by the name of Sabrael. There was one form of Sabrael which cannot strictly be called idolatry, as it did not involve the use of idols, but addressed itself directly either to the heavenly bodies themselves, or to the element of fire, with which they were associated. But the same object of religious worship, coupled with the use of idolatrous representations, is found in the worship of Baal, of Moloch, and of Tanmuzz, the Phoenician Adonis, or Astarte (see Astarte, xiv.). 4. A certain form of idolatry, and that which prevailed in the later period of the ancient Gentile religions, was Andropolatry, or the worship of representations of the human form. It is chiefly familiar to us through the mythology of Greece and Rome, but it also found a place in most of the other religious systems, in some of which the representations of the human form were variously modified, so as to symbolise those special attributes which formed the peculiar objects of the worshippers' adoration. Of this
there are many examples in the mythological repre-
sentations of the Egyptians and of the Indians.
The Egyptian religion, indeed, and in the later
periods of the idols were representations of
pure abstractions, as of certain faculties or affections
of the mind, of virtuous desires, or of evil passions.
Nor can it be doubted, that among the more cul-
tivated classes, there were individuals by whom these
abstractions were fully understood, and by whom
the crude idolatry of the multitude was regarded
solely as a device adapted to their more gross and
material conceptions.
The Jews, notwithstanding the many safeguards
by which the head of the one Supreme Being was
protected in their religious system, were frequently
seduced into the idolatrous worship of the Gentile
nations among which they were thrown. It is one
of the most remarkable among the anomalies of
the history of this singular people, that the great
and radical purification of their faith in the unity
of God dates from their protracted Babylonian
captivity, from which time it was maintained, not-
withstanding the effort of Antiochus Euphanes to
introduce the Greek idolatry (1 Macc. i.), down
to the coming of our Lord. The idolatry into which
the Jews fell at different periods was chiefly of the
first and the third forms described above.
In the idolatry of the savage tribes of the African
and Oceanic races is for the most part of the class
described under the head FETISHISM.

IDRIA, a small but important town of Austria,
in the crownland of Carniola, celebrated for its
quicksilver mines (discovered in 1467), is situated
in a deep, caldron-shaped valley, on a river of the
same name, 22 miles west-south-west of Lajbach.
The descent to the mines is by 757 steps, hewn in
the rock, and is easy, and free from danger. They
are the richest in Europe. Upwards of 220 tons of
quicksilver are produced here annually, and
about 60 tons of cinnabar (red sulphuret of mercury).
Pop. 4,500, about 400 of whom are regularly employed as miners, the others chiefly
in the manufacture of linen and silk fabrics and
bone-lace; and in distilling spirits.

IDUMEA. See EDOM.

IDUN, or IDUNA, the name of a goddess of
the northern mythology. She was the daughter of the
dwarf Valfi; but being received among the
Aesir, married the wife of Bragi. I possessed a
precious apple, by the use of which the gods pre-
served their perpetual youth. She was carried off
by the giant Thiaasi, with the assistance of Loki;
but the gods sent the latter after her, to bring her
back, which he did, after changing himself into a
falcon, and I, into a nut.

IDYLL (Gr. eiddiion, Lat. idyllium, a little
image), a term generally used to designate a species
of poem representing the simple scenes of pastoral
life. It is, however, an error to suppose that the
idyll is exclusively pastoral; certainly, there is no
warrant for such a notion in the usage either of
the ancients or the moderns. Of the thirty Eddyia
of Theocritus, not more than one-half are pastoral
in their character. After the use made of the word
by Tennyson, in his Idylla of the King, which are
epic in their style and treatment, and romantic and
tragic in their incidents, it becomes very difficult
to say what is not an idyll.

Iglawa, the old walled town of Austria, in
the province of Moravia, is situated on the river
Iglawa, close to the Bohemian boundary, 49 miles
west-north-west of Brünn. It consists of the town
proper and of three suburbs. In the midst of the
spacious and beautiful town square, stands the guard-
house. I carries on spinning, dyeing, and brewing,
IGNATIUS' BEANS—IGNIS FATUUS.

basis of genuineness, but to have suffered extensive interpolation. The reason why these epistles have excited so keen an interest, especially among ecclesiastics, is, that the question of church government is believed to hang very much upon them; they are the foundation-stones of Episcopalianism and Presbyterianism; and as they seem to favour the hierarchical system of the former, Episcopalians have, as a rule, been strenuous in defence of their legitimacy, while Presbyterians have as warmly attacked it. The discovery, in 1838, of a Syriac version of three of the epistles—those to the Romans, the Ephesians, and to Polycarp—published by the Rev. W. Cureton, formerly of the British Museum, under the title of The Ancient Syriac Version of the Epistles of St Ignatius, &c. (Lon., 1845), has, on account of its possessing higher claims to be considered genuine than any Greek MSS., led to the conclusion that the common Greek text has been very seriously tampered with— the interpolations consisting often of passages enforcing episcopal authority, and asserting the deity of Jesus Christ.

The best parts of the writings ascribed to I. I are contained in the Patrologia Antiqua of Cotelarius (2d edit. Amst. 1724); of those commonly held to be genuine, by Jacobson (Oxfor, 1838); various translations of the seven epistles have been made into English—the best known is that by Archbishop Wake.

IGNATIUS' (Sr) BEANS, the seeds of the Ignatia amara, formerly Strychos Ignatii, a tree of the natural order Loganiaceae, and nearly allied to that which produces Nux vomica (q. v.), a native of Coch-in-China and of the Philippines Islands. The tree is of the size of a large pear, and contains about twenty brownish seeds, of about the size of olives, rounded on one side, and somewhat angular on the other. These seeds came into the Dutch shops under their present name about the end of the 17th c., but there is some reason to think that they are the nux vomica of earlier writers. They contain strychnæ, and their medicinal uses are similar to those of nux vomica.

IGNATIUS LOYOLA. See LOYOLA.

IGNEOUS ROCKS are those which have been produced from materials fused by heat. They differ from the sedimentary rocks in their origin, structure, and position. They invariably come from below upward, breaking through the older rocks. The materials of sedimentary strata are fragments of pre-existing rocks, worn, by the action of water, either into a fine mud or into rounded particles, of greater or less size; whereas igneous rocks exhibit either a vitreous structure, as when they have been quickly cooled; or a granular structure, composed of more or less minute crystals, according to the rate of cooling; or a voleanic structure, when they have been expanded by the contained gases, or by being brought into contact with water. Some rocks are erroneously called igneous, whose materials, though originally obtained from volcanoes, are changed by underground source, have yet been ultimately arranged by water, like the materials of Graham's Island (q. v.). When this fact receives due consideration, many igneous rocks, whose position is now a puzzle, will be easily explained. Some of the rocks composing Arthur's Seat, near Edinburgh, are undoubtedly of this character, and before a right theory of the hill can be constructed, these must be separated from the truly igneous rocks. In position, also, the igneous may be distinguished from the sedimentary rocks, for they seldom occur regularly stratified, with a parallel upper and under surface, but are generally local, thinning out into wedge-shaped beds, or having that irregular stratification which may be seen in modern lava. They also occur as upright walls or dykes, filling up cracks in the sedimentary strata.

The most satisfactory classification of the igneous rocks is based upon their age. The three obvious divisions thus established are each characterised by peculiar mineral and structural differences. The oldest or Granitic series (q. v.) are generally associated with the Palaeozoic strata, but are sparingly found in the Secondary, and even in the Tertiary formations. The special peculiarity of the granitic rocks is the great abundance of silica contained in them; it forms not only a considerable amount of the constituents of the hornblende and felspar, but crystallises free in the rock-mass as rock crystal. The Trappinean Rocks (q. v.) are associated with the Palaeozoic and Secondary strata, and are composed of crystals of felspar and hornblende, varying in their character usually, but the redolence of the one or other of these ingredients. The Volcanic (q. v.) are the newest igneous rocks; they belong to the present period, or the Tertiary strata. The chemical ingredients are the same as those contained in the other rocks, but those that differently built up, being the peculiar form the silicate of magnesia and lime assumes in the newer rocks, while it appears as hornblende in the older or Trappinean series.

IGNIS FATUUS (Lat. 'vain or foolish fire') is a luminous appearance frequently seen in marshy places, churchyards, and over stagnant pools, which has puzzled philosophers from the time of Aristotle. It generally appears a little after sunset, as a pale greenish blue, sometimes white, and sometimes it shines steadily till morning, at other times disappears, and reappears within about half-hour intervals. It floats in air at about two feet from the ground, is sometimes fixed, and sometimes travels with great rapidity. In general, it recedes on being approached, and vice versa, though several successful attempts have been made to light a piece of paper by it. Many efforts have been made to discover its cause; but the redolence of its appearances, and so void of any common principle, that these attempts have totally failed. Of the various theories advanced we need mention only two. The first is, that the ignis fatuus is due to phosphatated hydrogen gas (H₂P), which possesses a spontaneous ignition on coming in contact with dry atmospheric air; the gas would be generated by the decomposition of animal matter present in a marshy soil. The motion of the ignis fatuus is accounted for by the flame being communicated along the line of a stream of the gas. The second is, that it is due to the combustion of light carburated hydrogen gas (C, H₄), arising from the decomposition of vegetable matter; but though this supposition satisfactorily accounts for many appearances connected with the ignis fatuus, the gas itself is not spontaneously combustible, and an additional supposition requires to be made to account for its ignition. The probable conclusion is, that a number of pheno- mera similar to the eye, but arising from different causes, are aggregated under the term ignis fatuus. The ignis fatuus, however, has never been produced artificially. Electricity and phosphorescence can produce the luminous appearance, but, as far as our present knowledge enables us to judge, they are unable further to imitate it.

It is not a common phenomenon, many distinguished naturalists never having seen it; but it is not unfrequently seen in the north of Germany, the swampy and moorland districts in the south and north-west of England, and in the Lowlands of Scotland. It is seen in the above places from the
middle of autumn till the beginning of November. In former times, the ignis fatuus, under the names of Will-o’-the-wisp, Jack-a-lantern, Sparkle, &c., was an object of superstitution among the inhabitants of the districts where it appears, and was believed to be due to the agency of evil spirits attempting to lure the traveller to his destruction; and, unfortunately, there are too many instances on record of travellers mistaking the ignis fatuus for a lamp, and being thus decoyed into marshy places, where they perished.

IGNORAMUS (Lat. we do not know), the word formerly written by a grand jury on the back of an indictment, meaning that they rejected it. The words now used are 'Not a true bill,' or 'Not found.'

IGNORANCE OF THE LAW, or IGNORANTIA JURIS, is held in law to be no excuse for any breach of contract or duty, nor for crime or other offence. The law is to start with this maxim, otherwise it would be quite impossible to administer the law, for if once a contrary maxim were allowed, it would not only be a premium to ignorance, but would lead to endless and abortive inquiries into the interior of a man's mind. Ignorance of a fact, however, is a different thing. Another kindred maxim of the law is, that every man intends the consequences of his own act. Thus, if he shoot at or give poison to a person, it is presumed that he intended to kill such person. So, if he leave a trap-door open in a street or thoroughfare, it is held that he intended people to fall into it and be injured. There is, however, a doctrine called bona fide, which in the case of petty offences punishable by justices, often tempers the strict and rigid application of the maxim, ignorantia juris neminem excusat; and even in crimes, a judge always takes into consideration, when passing judgment, whether the prisoner or defendant was an ignorant or intelligent person.

IGNORANTINES (Fr. Frères Ignorantins), a religious congregation of men in the Roman Catholic Church, associated for the gratuitous instruction of poor children in sault as well as secular learning. It was founded in France in the early part of the 18th c. (1724), by the Abbé de la Salle, and has gradually been introduced into every Catholic country of Europe. In France, this congregation shines at the head of the Revolution; for all the other religious bodies; but the brethren, under the name of Brothers of the Christian Schools, were recalled, and re-established under Napoleon in 1806. They are now exceedingly numerous in France, Italy, and Germany, and many branches exist in England and Ireland. In the latter country, they possess, especially in Dublin, Cork, Limerick, Waterford, large educational establishments; and they have published for the use of their schools a series of school-books, which are designed to combine with secular knowledge information on the subject of religion, specially designed for Roman Catholic pupils.

IGUALADA, a town of Spain, in the modern province of Barcelona, and situate about 40 miles west-north-west of the city of that name, on a rising ground on the left bank of the river Noya. It is for the most part closely built, dark, and dirty; carries on manufactures of cotton and woollen goods, hats and firearms, is the seat of considerable trade, and contains a population of 10,000.

IGUANA, a genus of saurian reptiles, the type of the family Iguanidae, a family which contains many genera and species, and to which belong some of the largest saurians now existing, except those of the crocodile family. Far larger saurians allied to them existed in former geological periods. See Iguanodon.

Iguanodon. The Iguanidae have a lizard-like form and a long tail. The tongue is thick, fleshy, not extensible, and is notched at the tip. They have rows of small teeth on the palate, and their jaw-teeth are remarkable both for their form and mode of insertion, not being lodged in distinct sockets, but fixed in a kind of furrow along the internal face of the jaw-bone, adhering by one side of the bony surface of the root. The food of the Iguanidae consists chiefly of leaves and fruits. They are all natives of warm climates. In the genus I., the back exhibits a row of elevated, compressed, pointed scales along its whole length, and which is continued to the extremity of the tail; whilst under the throat is a great dewlap-like pouch. The feet have long toes, not webbed, with sharp claws, well adapted for climbing trees, while the compressed tail is the organ of progression used in swimming. The Common I., or Guiana, is abundant in the West Indies and tropical parts of America, living mostly among trees. It attains a length of four or five feet. It is of a greenish-yellow colour, mottil with green, the tail ringed with brown. It is esteemed a most delicate article of food, and is used by all classes of persons. It is often caught by means of a noose thrown over its head; dogs have also been trained to hunt it on some of the West India ises, where it has not opportunity of taking refuge in trees. The eggs—which are about the size of those of a pigeon, but have no hard shell, and are laid in the sand—are also eaten, and are very pleasant. Other species of I. and nearly allied genera are eaten in tropical America, as the Hermil I. (L. cornuta or Metaposorus cornutus) of Hayti. The true iguanas are all American.

IGUA'NODON (Iguana, and Gr. odous, tooth), a genus of remarkable gigantic dinosaurian reptiles, more abundant in the Wealden beds of Kent, Sussex, and the Isle of Wight, than any other genus of associated saurians. Their singular structure, differing in many important particulars from any known reptile, long caused great diversity of opinion as to their true affinities. Dr Mantell, their original discoverer, and their learned expounder, first, knew of their existence from some enormous bones, which, notwithstanding their colossal size, he considered reptilian. A large tooth next turned up, whose smooth worn crown attested its having belonged to a herbivorous animal. Numerous other specimens of teeth were in progress of time discovered, and Dr Mantell found that they corresponded in a remarkable manner with the teeth of the small American lizard, the iguana, although they exhibited very striking and
important differences. Since the original discovery of the teeth, several other portions of this remarkable reptile have been found. The fragmentary and imperfect materials which have yet turned up make any estimate of the size of this animal purely hypothetical. Dr Mantell's estimate is as much as 70 feet in extreme length, while Professor Owen considers it to have been not over 28 feet.

The structure of the skeleton is very remarkable. The fragments of the upper and lower jaw shew that the head was produced into a short snout, which supported a nasal horn. The vertebral column was somewhat fish-like; the joints being slightly concave on both surfaces, yet it had lofty neural arches, and the sacrum was composed of five ankylosed joints, a structure found in no other reptile. The limbs were long and strong, raising the body some distance from the ground. The largest femur yet found measures four feet eight inches in length, and the shaft has a circumference of twenty-five inches. The leg terminated in a three-toed foot, which produced the enormous tridactyle impressions on the argillaceous Wesleyan beds that were once time considered to be the footprints of huge birds. The discovery by Professor Owen of all the bones of a perfect foot, however, conclusively connects these impressions with the iguanodon. His figure,

of Swedish philology. It was got up at the cost of the state, which gave L 10,000 dollars to execute it. His numerous academical disputations, amounting to upwards of 450, are still valuable, especially those on the Mosco-Gothic version of the Gospels by Ullias.

IKUPA, the principal river of Madagascar (q.v.).

FLECHESTER, a small and decayed town of England, in the county of Somerset, is situated in the rich valley of the Yeo or Ivel—from which it derives its name—33 miles south-south-west of Bath. The principal buildings are the parish church, an ancient structure surmounted by a low octagonal tower, and the county jail. I., supposed to be the Ischalis of Ptolemy, was the principal station of the Romans in this region, and was fortified by them with a strong wall and ditch, both still traceable. Numerous Roman remains have been found here. L. is the birthplace of Roger Bacon. Pop. (1861) 781.

ILE-DE-FRANCE, one of the old provinces of France, having Paris as its capital, and now mostly comprised in the departments of Seine, Seine-et-Oise, and Oise. During the last century of the Carlovingian dynasty, the Île-de-France was possessed by a race of powerful nobles, who latterly took the title of Dukes of France. One of the most able of these was Hugo or Hugues, surnamed le Blanc, or Le Grand, who, for 20 years previous to his death (956), virtually wielded the sovereign power under the Carlovingian kings Louis IV. and Lothaire. His son, Hugo Capet, eventually became the actual sovereign. See Capetian Dynasty.

ILETZK, or ILETSZKA ZASHCHITA, a small town and fort in Eastern Russia, on the border of the Kirghiz territory (government of Orenburg), situated on the bank of its canal and near the confluence of the Ural, in lat. 51° 9' N., long. 54° 59' E. The town was founded by Cossack emigrants in 1737, and now contains a population of 2424 inhabitants. It is remarkable for its quarries of rock-salt, the richest in Russia. The salt-beds of I. were formerly worked by the native Bashkirs, but since 1754, both the extraction and sale of the salt are monopolised by the government, and are the source of considerable revenue. All the country round I., especially along the river Solianka, is one continual layer of salt, covered with a sandy or clayey alluvion, 3 to 4 feet thick. The thickness of the salt bed is not yet thoroughly ascertained, notwithstanding many investigations, from Pallas up to the present time. The I. salt is considered the best in Russia. On the surface of the bed, cubic blocks of salt are found, pure and transparent like crystal, and weighing from 3 to 10 lbs. each. Various small articles are manufactured out of such blocks, and the common people ascribe to them a healing virtue in ophthalmic disease. The quantity of salt worked in 1839 was 4354 tons; in 1856, it was above 14,000 tons.

ILEUM. See Digestion, Organs of.

ILEUS, or ILLAC PASSION, is regarded by some writers as a distinct disease, but is in reality the closing stage of the severest forms of enteritis, or of colie, and is often connected with some irremovable mechanical obstruction. It may indeed occur in any case in which the contents of the bowel cannot find their way onwards. The peristaltic action of the intestines is inverted; there is intense vomiting, and even feculent matter is discharged by the mouth. Desperate as the condition of the patient is, his case is not absolutely hopeless; but as recovery, when it occurs, is due rather to nature than to art, it is unnecessary to enter into the subject of treatment.
ILEX—ILLINOIS.

ILEX, a tree often named in the Latin classics, the Evergreen Oak or Holm Oak (Quercus llex). See OAK. It is native of most parts of the south of Europe and of the north of Africa, often attaining large dimensions, as it sometimes does where planted in Britain. It grows in general singly or in small groups, and loves the vicinity of the sea. Its leaves are unusually acute, empty beneath, hairy beneath, but they vary much in some respects, from the size of a sloe-leaf to that of a beech, and from being very spiny at the edge to perfect evenness. It is a very ornamental tree and has not been much planted in Britain as it deserves. Its wood is very hard and heavy, tough, durable, and useful, particularly for axles, pulleys, screws, and whatever is to be subjected to much friction. The acorns are of various quality, sometimes better, and sometimes sweet and eatable. In modern botany, llex is the generic name of the Holly (q. v.).

'ILFRACOMBE, a small market-town, seaport, and watering-place of England, on the north coast of the county of Devon, is finely situated amid picturesque irregular hills, on a cove or inlet of the Bristol Channel, 11 miles north-north-west of Barnstaple. The harbour is formed by ramparts of rock, and furnished with a light-house, and a pier 800 feet in length. The bathing establishment is a Lilliputian style, and may be supplied with sea-water from the shore by means of a tunnel. The town is chiefly dependent upon its wealthier residents and its summer visitors; but an active fishery and coasting-trade are also carried on.

Pop. (1861) 3039.

ILLAC ARTERVES. The Aorta (q. v.) divides at its lowest point—which is usually on the left side of the body of the fourth lumbar vertebra—into the two common iliac arteries, which pass downwards and outwards on each side to the margin of the pelvis for about two inches and a half, and then divide into the external and internal iliac artery of either side. The external iliac passes obliquely downwards and outwards to the femoral arch, when it enters the thigh, and becomes the femoral artery. The internal iliac is a short vessel, about an inch and a half in length, which divides into an anterior and a posterior trunk. The anterior trunk divides into several branches, which supply the bladder, the rectum, the generative organs, and muscles both within and on the outside of the pelvis, with arterial blood; while the branches of the posterior trunk mainly supply muscles within and on the outside of the pelvis. The importance of the internal iliac artery in carrying on the circulation in uterine life is noticed in the article Fetus.

ILLISSUS. See ATHENS, and ATTICA.

ILLIUM. See PELVES.

ILLIUM. See TROY.

ILKЕSTON, a thriving market -town of England, in the county of Derby, and situated ten miles north-east of the town of that name, on an eminence in the valley of the Erewash. Manufactures of hoseery and stockings are carried on, and the power of the inhabitants are employed in the coal and iron works of the vicinity. Pop. (1861) upwards of 8000.

ILLE-ET-VILAINE, a maritime department in the north-west of France, formed out of a portion of the old province of Brabant, is quadrangular in shape, and bounded by the English Channel and the department of Loire-Inférieure. Area, 2573 square miles, or 1,664,670 square acres, of which 1,016,580 acres are arable land; pop. (1862) 584,930. It is watered chiefly by the rivers from which it derives its name—the Vilaine, and its tributary, the Ille. The usual grain-crops are raised in sufficient quantity to meet the wants of the population. Flax and hemp are extensively produced, and the cider of this district is esteemed the best produced in the country. Cattle are reared in great numbers, iron mines are worked, and great varieties of linen and woollen fabrics are manufactured. The department is divided into six arrondissements—Rennes, Châteaudun, Montrouge, Saint Malo, Vitré, and Redon. Rennes is the capital, and St Malo the principal seaport.

ILLEGITIMACY. See LEGITIMACY; BASTARDS.

ILLICHIUM, a genus of trees of the natural order Magnoliaceae, having flowers with three or six petal-like sepals, numerous petals arranged in several rows, and numerous stamens and pistils; the capsules arranged in a star-like form, opening upwards, and each containing a single seed. The species are few, but very widely distributed. The most important is I. anisatum, the fruit of which is known as Star Anise, or Chinese Anise. See Anise. This tree is held in high estimation among the Japanese, and is planted near their temples, as their gods are supposed to delight in it. Among the other species is I. floridanum, a shrub with few pendent clusters of dark purple flowers, native of Florida and Louisiana, of which the leaves are very fragrant, the capsules also smelling of anise, though more faintly than the I. domesticum. Similar in fragrance is I. jardiimerum, another Floridian species.

ILLIMA'NI, one of the principal mountains of the Bolivian Andes. See ANDES.

ILINOIS, a river of North America, is formed in the north-east portion of the state of Illinois by the union of the Kankakee and Des Plaines, flows south-westward through the Mississippi valley to the mouth of the Missouri. It is 500 miles long, and is navigable for 245 miles. It is broad, deep, and sluggish, and widens occasionally into lake-like expanses. It is connected by a canal with Lake Michigan.

ILINOIS, one of the United States of America, extending from 36° 56' to 42° 30' N. lat, and 87° 35' to 91° 40' W. long, being 388 miles long, and 212 wide: containing an area of 33,405 square miles, or 35,430 square miles. It is bounded N. by Wisconsin; E. by Lake Michigan, and the state of Indiana, from which it is partly separated by the Wabash river; S. by the converging rivers Mississippi and Ohio, which separate it from Missouri and Kentucky; and W. by the Mississippi, which separates it from Missouri and Iowa. The state is divided into 101 counties; the capital is Springfield, near the centre of the state, and the most important towns are Chicago, the principal port on Lake Michigan, Galena and Alton on the Mississippi, and Cairo, at the southern terminus of the Central Railway, and the confluence of the Ohio and Mississippi rivers. The population of the state has increased with marvellous rapidity. In 1810, it was 122,292; in 1820, 55,211; in 1830, 157,445; in 1840, 474,183; in 1850, 851,470; and at the last census of 1860, 1,711,753. More than half the people of I. were born in other states or foreign countries, a large number being Irish and Germans. In 1830, there were but 707 paupers in a population of 851,470. The state of I. is generally level, having few hills and no mountains. The lowest portion is but 340 feet, and the highest only 800 feet above the Gulf of Mexico. It is nearly drained by the Mississippi, which is covered with a narrow bed of very shallow water, with a soil of vegetable mould 40 feet in depth, have produced heavy crops of maize for many successive years without manuring. The country is so level that the canal which unites Lake Michigan with Illinois river and the Mississippi is fed by water pumped from the lake to a height of twelve feet.
ILLUMINATED MANUSCRIPTS— ILLUSTRATED PUBLICATIONS.

The principal rivers, besides those which form the boundaries, are the Illinois and Rock rivers, and their tributaries. The whole state is of limestone formation, with rich lead deposits in the north-west, and a large portion of the great bituminous coal formation, 375 miles long and 200 wide, lying in this and the adjoining states. The climate is mild, with an average of 77° Fahr., in summer, and 32° in winter, but ranging from 20 below to 100° above zero; it is also healthy, except in swamp-lands or river-bottoms, which are subject to fever and ague and bilious diseases. The productions are wheat, maize, tobacco, cattle, hogs, apples, pears, peaches, grapes, &c. There are over 300 miles of railway, including the Illinois Central, 708 miles, and the Galena and Chicago, 459 miles.

In 1830, the state, 10,000 public schools, 500 private schools, 58 academies and seminaries, and 21 colleges. In 1850, there were 1233 churches; but the population having doubled since that period, there has been a proportional increase. In 1838, the Mormons occupied the city of Nauvoo, on the Mississippi; but in 1844, their prophet, Joseph Smith, was killed by a mob; and his followers, 20,000 in number, made their exodus across the plains to the territory of Utah. — I. was first explored by La Salle, and the French traders and Indian traders, who formed the earliest settlement at Kaskaskia, in 1673. Ceiled by France to Great Britain, and then to the United States, it remained a portion of the North-west Territory, until its organization as a state, with a governor and legislature, in 1818.

ILLUMINATED MANUSCRIPTS. See Manuscripts.

ILLUMINATED, a name which has at different periods been borne by four different societies—that of the Alembrados in Spain, in the end of the sixteenth century; that of the Guermites in France, about the year 1654, enthusiasts and visionaries; an association of Mystics in Belgium, in the latter half of the 18th century; and the Order of the Illuminati, which was founded at Ingolstadt on May 1st, 1776, and soon spread over almost all the Roman Catholic parts of Germany. It is this which is now commonly meant when the name Illuminati is employed. Its founder at first called it the Order of the Perfectibilists. It owed its existence to Adam Weishaupt, Professor of Canon Law at Ingolstadt, a man of deep religious feeling and laborious benevolence, but deficient in practical knowledge of mankind. Filled with detestation of Jesuitism, and impatient of the restrains which were at that time imposed on the human mind in Roman Catholic Germany, and in no part of it more than in Bavaria, under the bigoted administration of the Elector Charles Theodore, he conceived the idea of forming an association which should extend its ramifications everywhere, and should consist of the choicest spirits, should labour for the establishment of the dominion of reason, and promote religions and political enlightenment and emancipation. Religious dogmas and forms of worship were to be rejected, a system of disputation to be propagated, and republicanism opinions. The accession of the Baron von Knigge to the new order, and the support which it received from the Freemasons, led to its rapid extension, so that, at one time, more than 2500 of the most accomplished men in Germany were members of it. Weishaupt's knowledge of the order of the Jesuits led him to borrow some of their methods for the accomplishment of what he regarded as the merits of the sect; and the Illuminati were soon involved in a system of mutual espionage, confession, and the like, essentially inconsistent with true freedom, but calculated to place the threads all in one hand, by which the holy legion was to be led on, as it was imagined, to the benefaction of mankind. The order soon ensued. Weishaupt and Knigge, its two leaders, quarrelled with one another. The order began to be openly denounced as dangerous, and, on the 22d of March 1784, an edict was issued by the Elector of Bavaria for its suppression, which was followed by another on 2d March 1785. Weishaupt was degraded and banished. He retired to Halle, where he died in 1830, at the age of 83. Various other members were severely punished, and the form of justice was not strictly observed in the proceedings against them. Great importance was at one time attached to the order of the Illuminati, whose secret influence was regarded as a principal cause of many of the political events of the time of the French Revolution, and the works of Abbé Barruel and of Professor Robison of Edinburgh upon this subject were eagerly read, but the highly exaggerated character of their views is now generally acknowledged.

ILLUSIF. See Bassia.

ILLUSORY APPOINTMENT, a legal phrase which denotes that where a person has a power or faculty to divide property among several others, such as children, and he gives one or more a very small sum, and the bulk of the property to the rest, the former is called an illusory appointment. In vulgar parlance, it is like cutting off an heir or child with a shilling. In general, it is competent, both in England and Scotland, to make an illusory appointment, but much depends on the peculiar terms of the deed or will originally giving this power to appoint or divide.

ILLUSTRATED PUBLICATIONS are a remarkable feature of the literature of our times. The employment of illustrations or pictorial sketches to render books more intelligible and attractive, has long been considered, but has of late years been carried to an extent previously unknown. There are two methods of illustration: by copper or steel plate engravings, which, being on leaves apart from the text, are printed separately; and by engravings, which, inserted as blocks in the typography, are printed as part of the work. Wood-engraving is not new, but it was little employed for general illustration until comparatively recent times. At the end of the 15th and the beginning of the 19th c., illustrations, for the most part, consisted of separate engravings on copper. See Engraving. In the early part of the 19th c., books of travels and works of a fanciful kind, and also in natural history, issued in London, were illustrated chiefly by aquatint engravings. Among the artists who were noted for this species of illustration were Rowlandson, John Clark, and the Cruikshanks, and as the engravings were coloured by hand, they were particularly attractive. Clark was principally employed to illustrate voyages and travels. In the preparation of designs for these illustrations, the author of the work was usually much indebted to the artist, who, in most cases, was, in addition, provided with only a few scratches to guide him in his representations. The use of aquatint engravings was at length superseded by lithography; but before this new species of illustration came greatly into vogue, wood-engraving took the place of all kinds of illustration except that of the high-class line steel-engravings, which are still in use for costly publications. The taste for illustrated works first sprang up in England, and the manner in which the Illuminati was soon adopted influenced the emancipation of Germany, and the United States. From 1820 to about 1830, was the great era of Illustrated Annuals (q. v.). The
taste for those illustrated year-books ultimately wore itself out, and was succeeded by a demand for highly illustrated books of poetry by popular authors, such as Rogers, Byron, and Campbell, and in the disposal of these elegant works, some publishers realised handsome fortunes. Latterly, illustration has consisted for the greater part in wood-engravings, for they possess the inestimable advantage of being printed with the letter-press, and in the hands of high-class artists, the design and execution of these embellishments have reached extraordinary perfection. Executed with comparative cheapness and rapidity, wood-engravings have been largely employed to illustrate a class of popular periodicals, and encyclopaedias, and newspapers. The Illustrated London News was the first, and continues to stand at the head of illustrated newspapers. See Wood-engraving.

**Ilyricum** (Gr. Ilyris, Ilyria) is the Roman name of a country whose limits in ancient times varied very considerably. In the 4th c. B.C., the Ilyrians, who are the ancestors of the modern race generally known as Albanians (see ALBANIA), inhabited the whole eastern coast of the Adriatic Sea and adjacent islands, with the western parts of Macedonia as far as Apulia. Philip of Macedon conquered the country as far as the river Drilon (modern Drin) in 357 B.C., and the invasion into Illyria (Greco and Ilyris Barbara or Romana. The former, now Albania (q.v.), was incorporated with Macedonia. Ilyris Barbara or Romana was divided into Iapodia, Liburnia, and Dalmatia. The Ilyrians were much addicted to piracy, which soon brought them into collision with the Romans, and led to their subjugation about two centuries B.C. They made numerous efforts to shake off the Roman yoke, but were always defeated, and the country became a most important province of the Roman empire, comprising the territory represented in modern times by Croatia, Dalmatia, Herzegovina, Montenegro, nearly all Bosnia, and a part of Albania. On the division of the Roman empire, I. shared, in the vicissitudes that followed that act. A decree of Napoleon, on 14th October 1809, gave the name of Ilyrian Provinces to Carniola, Dalmatia, and other countries from the Adriatic Sea to the Sava, then belonging to the French empire. By his fall, these provinces were united as a kingdom to the Austrian empire, and some alterations were made in its boundaries, especially by the restoration to Hungary of what had formerly belonged to it, and the severance of the western part of Carniola instead of the kingdom was divided into the two governments of Laisch and Trieste, Laisch being the capital, which arrangement subsisted till 1849, when it was subdivided, for administrative purposes, into the duchies of Carinthia (q.v.), Carniola (q.v.), and the coast district, containing the counties of Güz (q.v.), Gradiska, and Istra (q.v.), with the city and territory of Trieste (q.v.).

**Ilmenium** (formerly Mosel), a lake in North-western Russia, government of Novgorod, 27 miles long, 20 miles broad, and 16 feet deep. The lake is stormy, and unfit for navigation; its bottom stony. The rivers Shelon, Lovat, Mata, and several others, flow into the lake, which discharges its waters through the river Volkoff to Lake Ladoga. The lake abounds in fish, chiefly sandes, bream, and smelt, and fishing on its banks occupies a population of about 20,000. The lake L. is historically remarkable, because it was on its banks that the Shcherbatow, who, a little more than 562 years ago (562), invited the Vario-Jose to come and rule over them, from which time dates the origin of the Russian nation.

**Ilium**, the name applied by Hermmann to a new metal analogous to tantalum. He obtained its oxide from a mineral to which the various or marks of Urano-tantalite, Samaritake, and Yttrium-tantalite have been applied, and which occurs in the Ilmen Mountains in Siberia. Its existence as an independent metal is not satisfactorily proved.

**Iminster**, a small but ancient market-town of England, in the county of Somerset, is situated on the right bank of the Isle, 44 miles south-west of Bath. The Free Grammar and Commercial Schools, with an endowment of nearly £1000 a year, were founded in 1586. Some manufactures of woollens, silks, and lace are carried on. Pop. (1861) 3219.

**Ilbeide**, or EL OBEID (pronounced Lobeid), an important trading town of Africa, capital of the duchies of Gradiska, duchies of the Illyrian Empire, 20 miles from the delta of the Nile, and 30 miles from the Euphrates. It is about 560 miles south-west of the banks of the Niger, and about 150 miles north-east from the shore of the Bight of Benin. Nothing very definite seems to have been published regarding it. Dr. Barth, in conversing 135 years ago with an intelligent native who had lived for a long time in Constantinople, was told that it was ' without the least doubt larger than the latter city.'

**Illoir, Ilo'rin**, or, more properly, Alori, a very large town of Africa, the great centre of the Fulbe, in Yoruba, is situated in lat. 9° 30' N., and long. 4° 30' E., 46 miles south-west of the banks of the Niger, and about 150 miles north-east from the shore of the Bight of Benin. Nothing very definite seems to have been published regarding it. Dr. Barth, in conversing 135 years ago with an intelligent native who had lived for a long time in Constantinople, was told that it was ' without the least doubt larger than the latter city.'

**Il'sley, East,** a small but ancient market-town of Berkshire, England, is situated in a secrured hollow, and described in the early days of the 5th century. It is about 46 miles south-west of the banks of the Thames, and 50 miles west of London. It is remarkable chiefly for its sheep-markets, which are among the most important in the kingdom; 50,000 sheep have been known to be penned for sale here in one day. The ordinary sheep-fair is held every alternate Thursday from the Wednesday fortnight before Easter till July. The downs in the vicinity of the town are celebrated as training-grounds for race-horses. About a mile distant is the village of West Ilsley. Pop. (1861) less than 1000.

**Image-Worship** (Gr. iconolatria), the use, in public or private worship, of graven or painted representations of sacred persons or things, and especially the exhibition of honour, reverence, or worship to or towards such representations. This practice, in the various degrees of which it is susceptible, has formed, for many centuries, so fruitful a subject of controversy among Christians, that we think it expedient first briefly to detail, in history, the use of images in Christian worship during the several periods, and secondly to state summarily the opposite views of this history which are taken by the two great parties into which Christians are divided, as to the propriety of the use of images.
in the worship of Christians, whether public or private. The earliest allusion to such representations is found in Tertullian, who appeals to the image of the Good Shepherd as engraved upon the churches. A very curious pagan caricature of Christianity, of the very same age, lately discovered, scratched upon the wall of a room in the palace of the Cesar (see Graffiti), which rudely represents a man standing in the attitude of prayer, with outstretched arms and a very wretched crucifix, and which bears the title 'Alexandrian worship God,' has been recently alleged by Catholics as an additional indication of at least a certain use of images among the Christians of the 2d century. The tombs of the Christians in the Roman catacombs, many of which are of a date anterior to Constantine, frequently have gravestone upon them representations of the Dove, of the Cross, of the symbolical Fish, of the Ship of Adam and Eve, of Moses striking the rock, of Jonas, of Daniel in the lions' den, of the apostles Peter and Paul, and above all, of the Good Shepherd; and those compartments of the catacombs which were used as sepulchral, and particularly those which were decorated with representations, the age of which, however, it is not easy to determine with accuracy. But whatever opinion may be formed as to particular instances, such as these, it is admitted by Catholics themselves (with the exception of the destruc-
cubic root of $-64$ is not an imaginary quantity, for

$$-4 \times -4 \times -4 = -64,$$

and therefore $\sqrt[3]{-64} = -4$.

But the square root of $-64$ is an impossible quantity,

so $\sqrt{-64}$ is an impossible quantity (whether it

is defined or not). By itself it can produce a negative

quantity; similarly and fortorti, the fourth root of $-64$

is an impossible quantity, and the same is true of

all even roots. Imaginary quantities are, however,

generally reduced to one denomination as multiples

of $\sqrt{-1}$, in the following manner:

$$\sqrt{-64} = \sqrt{64} \times \sqrt{-1} = 8 \times \sqrt{-1}.$$

These forms very frequently occur in
gerher algebra.

**IMAGINATION.** The meaning of this word

enters into many relationships, and is thereby

rendered difficult to define. The principal meaning

doubtless is that which connects it with Poetry and Fine
Art, from which the other significations branch off.

The simplest mode of explaining this complicated relationship once was by stating in separation the different constituents of the power in question. We

shall then see why and where it touches upon other

faculties, which still require to be distinguished from

1. Imagination has for its objects the concrete, the

real, or the individual, as opposed to abstractions and

generalties, which are the matter of science. The

full colouring of reality is implied in our imagina-
tion of any scene of nature. In this respect, there

is something common to imagination and memory. If we

endeavour to imagine a volcano, according as we

succeed, we have before the mind everything

that a spectator would observe on the spot. Thus

densation, memory, and imagination alike deal

with the fulness of the actual world, as opposed to

the abstractions of science and the reasoning

facilities.

The faculty called conception, in one of its meanings,

has also to do with this concrete fulness, although,
in what Sir William Hamilton deems the original

and proper meaning of that word, this power is

excluded. In popular language, and in the phil-
osophy of Dugald Stewart, conception is applied to the

operation of immediately realizing an image of actual

life, as given in history or in poetry. When we

completely enter into a scene portrayed by a writer

or speaker, and approach the situation of the

actual observer, we are often said to conceive what

is meant, and not to imagine it; and this is the best word for

this signification probably is 'realise.'

2. It is further essential to imagination in its

strictest sense that there should be some original

construction, or that what is imagined should not

be a mere picture of what we have seen. Creativ-

ess, origination, invention, are names also design-

ating the same power, and excluding mere memory,
or the literal reproduction of past experience. Every

artist is said to have imagination according as he

can raise to new combinations or effects different from

what he has found in his actual observation of

nature. A literal, matter-of-fact historian would

be said to be wanting in the faculty. The exact

copying of nature may be very memorable in an

artist, and very agreeable as an effect, but we should

not designate it by the term imagination. There

are, however, in the sciences, and in all the common

arts, strokes of invention and new constructions, to

which it might seem at first sight unfair to refuse

the term in question, if originality be a leading

feature in its definition. But still we do not usually

apply the term imagination to this case, and for a

reason that will appear when we mention the next

personality attaching to the faculty.

3. Imagination has for its ruling element some

emotion of the mind, to gratify which all its con-

structions are guided. Here lies the great contrast

between it and the creative force of science and

mechanical invention. These last are instrumental

to remote objects of convenience or pleasure. A

creation of the imagination comes home at once to

the mind as matters of immediate view.

Wherever we are under the mastery of some

strong emotion, the current of our thoughts

is affected and coloured by that emotion; what chimes

in with it is retained, and other things kept out of

sight. We also form new constructions that suit the

state of the moment. Thus, in fear, we are over-

whelmed by objects of alarm, and even conjure up

spectres that have no existence. But the highest

example of all is presented to us by the construc-
tions of fine art, which are determined by those

emotions called aesthetic, the sense of beauty, the

pleasures of taste; they are sometimes expressly

styled 'pleasures of the imagination.' The artist

has in himself those various sensibilities to an

unusual degree, and he carves and shapes his

creations with the view of gratifying them to the

utmost. Thus it happens that fine art and imagina-
tion are related together, while science and useful

art are not. We are free and bound with our reason and

faculty which may also be faculties of invention. It is a

deviation from the correct use of language, and a

confounding of things essentially distinct, to say

that a man of science stands in need of imagination

as well as of reasoning; he needs the faculty of

original construction, but his inventions are not

framed to satisfy present emotions, but to be instru-

mental in remote ends, which in their remoteness

may excite nothing that is usually understood as

emotion. The faculty of invention is the soul of

art, and the soul of art is the faculty of invention, for

when he produces anything original in art.

The name 'Fancy' has substantially the

meanings now described, and was originally identical

with imagination. It is a corruption of fantasy,

from the Greek "phantasm, the changed into,

127

which has the title of Imaum, or the
IMMATURE. See EMBRATTED.

IMMUTABILITY must not be confounded with idiosyncrasy. In the former, there is the imperfect development of mind; in the latter, there is the soul-development of mind. In the feeble intellect, there may be present every faculty which distinguishes the most gigantic understanding. These may act under ordinary laws; but they are dwarfed, incapable of continued growth and training, and are exercised and applied under the guidance and assistance of others, or of external circumstances. There are large numbers of weak-minded, helpless persons in every community, who differ from the more robust intellects solely in degree. But the more marked and recognisable imbecility, as transmitted congenitally, as following dementias, chorea, convulsions, and diseases which retard vigorous bodily development, or as induced by the great constitutional changes at puberty, is characterized by all or many of the following symptoms. The expression is vacant, the senses are dull; the head is small, and the eyes are prominent; the gait is vacillating and restless; the head is pendulous, thrown back, or agitated; the saliva escapes; the language is limited and inarticulate; the ideas are few, and consist of repetitions of the same; the passions are tamed, facile, and vain; and the passions are little susceptible of control. The affection has been regarded as general, or involving the whole mind; or as partial, when the intellect only, or the sentiments only, or a particular faculty may be feeble and intractable.

In a legal view, such persons have been divided into those who have, and those who have not, a moral perception of right and wrong. It is, however, worthy of consideration, that while they may know right from wrong in their ordinary and habitual range of duties, and within the scope of their own capacity, they may fail to do so beyond these narrow limits, and where questions of property, of right, or abstract justice, are concerned. Many imbeciles are so vacuous, capable of performing acts requiring strength and endurance rather than dexterity; and in this country, as well as many others, they are not merely the 'naturals' who run everybody's messages, but they are converted into the domestic drudges of the homestead, the white slaves of the farm. From the more clever and cunning of the class were the professional tools of former ages selected. Imbeciles are often confounded with genuine idiots, and their partial culpability has exaggerated the supposed success in the attempts to effect and mature the embryo mind. However far this training may be carried, and even when the subject has become self-maintaining, it may be safely asserted that he is never self-governing nor self-governing, nor capable of an independent existence. — Howe, On the Causes of Idiocy; Reports, idiotic School, Earlwood; De L'Idiotie chez les Enfants, par Félix Voisin.

IMMUTABILITY, in point of law—i.e., something short of idiocy or lunacy—is no ground of relief in England against a contract, though relief is always granted in case of fraud, and the imbecility of one of the parties may form an element of the fraud. But if the person in any particular way protect an imbecile person or his property; for so long as a person is not actually insane or an idiot, he can do what he likes with his own. In Scotland, however, an imbecile person is to a certain extent protected against being imposed upon, as regards his heritable property, by a step called interdiction, which consists in either the imbecile, who is conscious of his weakness, executing a bond of interdiction, by which he puts himself under the care of a physician; or the court made necessary to render valid his contracts, or he may be judicially interdicted by the Court of Session, at the instance of his next of kin, with some effects. The trustees or guardians in such cases are called the interdictors. See LUXAET.

IMMER, or IMMER. See DIVER.

IMBROS, an island of the Ægean Sea, about 11 miles north-east of Lemnos, and the same distance from the mouth of the Dardanelles. It is 18 miles in length, and has an area of 116 square miles. The island is mountainous, its highest summit being 1848 feet above sea-level, and is covered with wood. Corn, wine, and cotton are abundantly grown in the valleys; oil is also produced. It contains four villages, the chief of which, called Imbro, is built on the site of an ancient city, named in the same name. Pop. of entire island about 4000.

IMBRUED, or EMBRUED, an expression used in heraldry to signify bloody, or dropping with blood. Weapons thus blazoned are drawn with drops of blood falling from them.

IMMERITA, formerly an independent Transcaucasian territory, now part of the government of Kutais (q.v.), is bounded on the N. by the provinces of Kla-ES, and on the W. by the districts of Ghiura and Mingrelia. Area, 4040 square miles; pop. 100,000. Its history as an independent dominion commenced from about the beginning of the 15th c., and was long marked by internal dissensions. In 1745, Salomon I. was proclaimed, but his subjects revolted shortly after, and aided by the Turks, dethroned him. Salomon applied for help to Russia, and in 1769, Count Tolstoi, at the head of a Russian force, entered I., restored the king, and drove back the Turks. The civil dissensions of this province, however, continued, and at last, in 1810, after having long acknowledged allegiance to Russia, it was formally incorporated in and proclaimed a province of that empire.

IMIDES. See ORGANIC BASIS.

IMITATION. See SYMPATHY.

IMITATION, in the science of musical composition, is the repeating of the same passage, or the following of a passage with a similar one, in one or more of the other parts or voices, and it may be either strict or free. When the imitated passage is repeated note for note, and every interval in the same, it is called strict, and it may take place in the unison or octave, or in any other of the degrees of the scale, either above or below the original passage. The progression of a passage may also be imitated by an inversion, or by reversing the movement of the original; also by notes of a greater or of a lesser value. See DOUBLE COUNTERPOINT, FUGUE, and CANON. Imitation in composition is one of the most useful means of producing unity and animation in the progression of the parts, and it is used in a strict, and also in a free manner, in the instrumental works of Haydn and Beethoven, and also by Mozart in his easier operatic works. Many composers have been led to imitate improperly, and generally from poverty of musical ideas, or from pedantry. No fixed rules can be given for its use.

IMITATIVE INSANITY. There are many mental diseases, especially those marked by grotesque external manifestations, by generalized convulsions, and convulsive seizures which appear to be propagated 936
by imitation. In the healthy and naturally constituted, there exists a tendency to copy and reproduce, or represent what powerfully impresses the imagination; and during the excitement of individuals or communities, this inclination is more influential, and passes beyond the control of the will. Great caution, however, must be exercised in distinguishing between what is epidemic and depends upon atmospheric or external moral causes, and from the results of strong or morbid states of the mind itself. An idiot is mentioned by Gall, who, having seen the slaughter of a pig, killed a man after the same fashion. A child of seven years old suffocated a younger brother on the suggestion of the strangled of Punch at the hands of the devil. The example of suicide by hanging having been set by a penitent in the Hôpital des Invalides, six similar deaths followed, and by suspension from the same tree, there appeared in succession seven female claimants to the parentage of Marie Antoinette; and pyromania, propagated by sympathy, is well known to hasten fatally in 1832.

IMMACULATE CONCEPTION OF THE BLESSED VIRGIN MARY, Feast of, a festival celebrated on the 8th of December in the Latin, and on the 9th in the Greek Church, in which latter church it is held under the name of 'The Conception of our Virgin Mary.' The festival of the Conception itself is traceable in the Greek Church from the end of the 5th c., and in the Latin dates from the 7th; but a great controversy prevailed for a long time in the 17th century as to whether the Council of Trent determined the date of the immaculate conception of the Blessed Virgin Mary to be held immaculate, and in what sense the Blessed Virgin herself was to be held conceived without sin. It is one consequence of the doctrine of the divine maternity, and a necessary part of the honour due to the Incarnation, that the Blessed Mother should be held to have been at all times free from the stain of sin. This might have been, either because she had been, like the prophet Jeremiah (Jer. i. 6), or the Baptist St John (Luke, i. 33), sanctified before her birth—that is, purified in her mother's womb from the stain of original sin; or by the still higher sanctification, when entering into the womb of the Virgin Mary, she was said to have commenced with St Bernard, who not only renounced with the canons of Lyon in 1131 for their unauthorised introduction of this festival in their cathedral, but rejected the opinion of the Blessed Virgin's having been conceived free from original sin, though he admitted her sanctification in her mother's womb (Epist. 174, Ad Canom. Lugdense). The discussion thus raised led to a protracted controversy in the school. The great master of scholastic subtlety, John Duns Scotus, in a disputation held before the university of Paris in 1307, maintained the doctrine of the immaculate conception in its highest sense; and the entire order to which he belonged, the Franciscans, to which school to which he has given his name, the Scottists, afterwards zealously defended it. On the other hand, the Thomist school, which was that of the Dominican order, having denied the immaculate conception, much division for a time existed; but the prevailing tendency was at all times towards the Scotist opinion. The university of Paris, in 1387, condemned the Thomist doctrine. The council of Basel—although, it is true, at the time when it was in conflict with the pope—declared the doctrine of the immaculate conception to be a Catholic dogma, and repudiated in the strongest terms the claim of the Scotists, as a contrary to their opinion. IV, and that of the defenders of both opinions, in 1470, the obligation of mutual toleration and charity, and renewed this constitution in 1483; but in the end of the same century the university of Paris required, in the name of the doctrine of the immaculate conception, that of the candidate that he would defend the dogma of the immaculate conception. The Council of Trent, without discussing the scholastic dispute, merely declared that 'in its decree on original sin it did not concern the church, an immaculate Virgin of Mary,' and renewed the constitution of Sixtus IV, already referred to. This abstinence on the part of the council led to a further renewal of the dispute, time, opinion was setting steadily the course of the 18th c., that Pius V. not only prohibited either such or from stigmatising the opposite with the name of heretical, but forbade all public discussions of the subject, except in theological disputations in the presence of a few Archbishops. In the pontificates of Paul V. and Gregory XV., earnest instances were made by the Spanish crown to obtain a definite declaration in favour of the doctrine of the immaculate conception; but the pope again refused, contesting the right of the papacy in creating the IV, and of Sixtus IV. He added, however, certain new provisions: 1. That disputants, in asserting the doctrine of the immaculate conception, should abstain from assailing the opposite doctrine. 2. That no one except the pope, or the Dominican order, in the opinion of Paul V. and Gregory XV., persons so specially privileged, should presume to defend, even in private disputations, the doctrine that the Blessed Virgin Mary was conceived in original sin. 3. That, nevertheless, in the public mass or in the church, no one should introduce into the prayers or other formulae any other word than simply conceptio, without adding any epithet involving either doctrine. At the same time, opined that the pope in the document should be an article of Catholic belief, and proposing it as such to the universal church. This decree has been implicitly accepted throughout the Roman Church.

IMMORALITY, in point of law, is a good defence to actions and suits, but it must be some immorality which runs counter to the well-known policy of the law. Thus, for example, if a man gave a bond, or granted a deed, giving to a woman some annuity, with a view to police laws to the end that, on an annuity, this would be a good defence against the bond or deed being enforced, for the law discourages his conduct; whereas, if it were merely a bond, or a gift, in consideration of something of the same kind past, and ended, the deed would be good. So the keeper of a house of ill-fame is not allowed to sue, and has no legal remedy against her guests for any sum agreed to be paid for immoral purposes. In most other respects, the mere personal
IMMORTALITY—IMPAOTION.

immorlality of the parties who are litigants makes no difference whatever as to their respective remedies, for the law protects the bad as well as the good, the unjust as well as the just.

IMMORTALITY is the continued existence of the human soul in a future life and in an immortal state. 'If a man die, shall he live again?' is a question which has naturally agitated the heart and stimulated the intellectual curiosity of man, wherever he has risen above the state of barbarism, and commenced to exercise his mental faculties. The belief of spirits engaged peoples may be said more or less to recognise the affirmative of the question,* although often under very vague and materialistic forms. In the ancient Egyptian religion, the idea of immortality first assumes a definite shape. There is a clear recognition of a dwelling-place of the dead and of a future judgment. Osiris, the beneficent god, judges the dead, and 'having weighed their heart in the scales of the right and the wrong,' sends them to regions of glory, while the just are sent to dwell with the god of light.' The latter, we read on an inscription, 'found favour before the great God; they dwell in glory, where they live a heavenly life; the bodies they have quit will ever repose in the tombs, whilst they rejoice in the life of the supreme God.'

Immortality is plainly taught, but bound up with the idea of the preservation of the body, to which the Egyptians attached great importance, as a condition of the soul's continued life. They built vast tombs, and embalmed their bodies, as if to last for ever. In the Zoroastrian religion, the future world, with its governing spirits, plays a prominent part. Under Ormuz and Ahirim, there are two great groups of spirits, one good, charged with a perpetual conflict; and the soul passes into the kingdom of light or of darkness, over which these spirits respectively preside, according as it has lived on the earth well or ill. Whoever has lived in purity, and has not yielded the dead (evil spirits) to have any power over him, passes from death into death into the realms of light. In the early Greek paganism, Hades, or the realms of the dead, is the abode of the souls, and regions of bliss to which the more perfect of Hellenic imagination, and the ideal of the soul, is the emblems of glory to the Homeric republic. In the progress of Hellenic thought, a bolder idea of the future is found to characterise both the poetry and philosophy of Greece, till, in the Platonic Socrates, the conception of immortality shines forth, with a clearness and precision truly impressive. In the Apology and the Phaedo, Socrates discourses of the doctrine of the soul's immortality, in language at once rich in faith and in beauty. 'The soul, the immaterial part, being of a nature so superior to the body, can it,' he asks in the Phaedo, 'as soon as it is separated from the body, be dispersed into nothing, and perish? Oh, far otherwise. Rather will this be the result. If it take its departure in a state of purity, not carrying with it any clinging impurities of the body, impurities which during its earthly life it never willingly or often avoided, gathering itself into itself, and making the separation from the body its aim and study—that is, devoting itself to true philosophy, and studying how to die calmly; for this is true philosophy, is it not?—well, then, so prepared, the soul departs into that invisible region which is of its own nature, the region of the divine, the immortal, the wise, and then its lot is to be happy in a state in which it is free from fears and wild desires, and the other evils of humanity, and spends the rest of its existence with the gods.' It is only in Christianity, however, that this higher life is clearly revealed as a reward not merely to the true philosopher, but to every humble and pious soul. Christ brought it; new life and immortality to light by the gospel. 'According to his abundant mercy, God hath begotten us again to a lively hope by the resurrection of Jesus Christ from the dead, to an inheritance incorruptible and undefiled, and that fadeth not away, reserved in heaven.' It is undoubtedly owing to Christianity that the doctrine of the soul's immortality has become a common and well-recognised truth—no mere result of speculation, nor product of priestly invention—but a light to the reason, and a guide to the conscience and conduct. The aspirations of philosophy, and the materialistic conceptions of popular mythology, are found in the gospel transmuted into a living spiritual and divine fact and an authoritative influence, not only touching the present life, but governing and directing it.

IMOLA (anc. Forum Cornelii, or Forum Sylla), a town of Italy, in the legation of Ravenna, stands in a fruitful plain adjoining picturesque hills, close to the river Santerno, and at the distance of two miles southwest of Ravenna. It contains some fine palaces, churches, theatres, and benevolent institutions. I, possesses some good manufactures of wax, oil, majolica, silk, and glass, besides extensive leather-curing establishments, and brick and tile works. From a species of white grape grown in the vicinity, the delicious wine known as vin santo is manufactured. Pop. upwards of 10,000.

IMPALE, in Heraldry, to arrange two coats of arms side by side in one shield divided per pale. It is usual thus to exhibit the conjoint coats of husband and wife, the husband's arms occupying the dexter side or place of honour, and the wife's the sinister side of the escutcheon. When a man marries a second wife, heralds say the second may divide the husband's half of the shield per fesse into two compartments, placing the family arms of his deceased wife in chief, and of his second wife in base. A husband impealing his wife with his own, is not allowed to surround the former with the collar or insignia of any order of knighthood to which he may belong. Bishop's, dean's, heads of colleges, and kings-of-arms, impale their arms with their insignia of office, giving the dexter side to the former. In early heraldry, when two coats were represented in one shield side by side, only half of each was exhibited, an arrangement which has been called dimidiation. Sometimes the one coat only was dimidiated. A reminiscence of dimidiation is preserved in the practice of omitting bordures, orles, and tressures in impaled arms on the side bounded by the line of dimidiation.

IMPAINATION (Lat. in, and passio, bread), a technical word employed in the Eucharistic controversies to express the peculiar opinion propounded by Luther as to the nature of the presence of Christ in the Eucharist. Differing from the Roman Catholics in denying the transubstantiation of the bread and wine, and from the Sacramentarians in denying that our Lord's presence was merely typical or figurative, Luther contended that the
body and blood of Christ were present in, or along with, the elements of bread and wine; in a manner analogous to that in which the divinity of Christ co-exists in the same person with his human nature. Hence, by an analogy with the word incarnation, he devised for the Eucharistic union the term impanation. This doctrine was the subject of a lengthened controversy with Zwingli at Marburg in 1529, which left each party unconvinced; and this controversy still continues to be the received one in the orthodox Lutheran schools.

IMPEACHMENT, the name given to an accusation and trial of a peer or member of parliament, or, indeed, any other person, before the High Court of Parliament, for treason, or some high crime or misdemeanour. This is a kind of trial which is reserved for great and enormous offenders, particularly in matters affecting the constitution, for the ordinary tribunals generally suffice for all cases of crimes. Impeachment, accordingly, is of rare occurrence, the last instance being that of Lord Melville in 1805, and it is one of the high prerogatives of parliament to try offenders in this way, it is still competent to use it. The proceedings nearly resemble an ordinary trial at law. A pardon by the crown is not pleaded in bar of the prosecution, though, after sentence, the crown may pardon the offender. See May, On Parliament.

IMPEACHMENT OF WASTE, an expression in English Law, used in deeds or wills. When an estate is given to a person for life, or for a term of years, without impeachment of waste, the tenant is entitled to cut timber, and do many things on the estate which otherwise he would be unable to do. Still, he is not allowed to do what he likes, for if he abuses his power, and attempts to cut down ornamental timber, for example, or deface the family mansion, the Court of Chancery will interfere by injunction to prevent this. The phrase is not used in Scotland, but the law is not materially different.

IMPELENTRABILITY, one of the essential properties of matter, implies that no two bodies can at the same time occupy the same space. If a nail be driven into a piece of wood, it does not, properly speaking, penetrate the wood, for the fibres are driven aside before the nail can enter. If a vessel be filled with fluid, and a solid body be then placed in it, as much water will run over as is equal in bulk to the solid body, in this way making room for it. The lightest gases are really as impenetrable as the densest solid; although, owing to their compressibility, it is not readily made apparent.

IMPERATIVE, CATEGORICAL. According to Kant (q. v.), man, in the consciousness of his moral liberty, recognises two great laws regulating his will; the first prompts him to seek his own well-being, the second commands him to be virtuous, even at the sacrifice of that. From this opposition in his moral nature between desire and conscience, springs up the idea of duty, which, in the Kantian terminology, is called the moral imperative, to which Kant adds the epithet categorical, to indicate that its commands are absolute and unconditional.

IMPERIAL CROWN properly signifies the crown borne by the German emperor; in form, a circle of gold, adorned with precious stones and fleurs-de-lis, bordered and seceded with pearls, and raised from the form of a cap voided at the top like a crescent. From the middle of the cap rises an arched fillet enriched with pearls, and surmounted by a globe, on which is a cross of pearls. In English heraldry, the form of crown worn by the kings of England (see King) is sometimes called a crown imperial; and a charge, crest, or supporter, crowned with a regal crown, is said to be imperially crowned.

IMPERIUM is a word used in the Roman law in various senses, the most important of which is that which it bears when applied to consuls and proconsuls—thence called imperatores. Most of the superior magistrates were also intrusted with the imperium, which meant a sovereign authority. It is of very little practical importance in modern times to trace the extent or precise nature of the authority thus designated, as the subject has little bearing on modern law.

IMPETINENCE, in English Law, means some irrelevant matter introduced in an affidavit or pleading; and the court will generally order it to be struck out, and the offending party to pay the costs of doing so.

IMPETIGO, a disease of the skin. It consists of crops of pustules, which may either be scattered or collected in groups. These pustules burst, dry up, and become covered with scabs or crusts of a yellow colour, not unlike little masses of candied honey. From beneath these crusts, a purulent discharge commonly takes place; the crusts become thicker and larger, and the skin around and beneath them is red and raw. The disease may be either acute or chronic. In the former case, it is attended with febrile symptoms, which must be combated by the internal administration of purgatives and alkalis, strict attention to diet, and weak alkaline lotions. In chronic cases, the discharge may be checked by a lotion containing ten or fifteen grains of oxide of zinc in an ounce of rose-water.

There are various forms of this complaint, as 1. figurata, 1. spuria, &c. The disease known as Crustacea lactea, which sometimes covers the faces of children like a mask, is a sort of compound of...
Impeyan (Lophophorus impeyanus).

exhibits—green, steel-blue, violet, and golden bronze.
The fine plumage, however, belongs to the male alone. The female is clothed in sober brown, mottled with gray and yellow, and is smaller than the male. The I. has been found capable of domestication, and may probably be found capable of naturalisation in Britain. It derives its name from Lady Impey, who first attempted to bring it alive to Britain, but failed. The Nepaunese name, Monaul, signifies Bird of Gold.

IMPLEMEN'T, in Scotch Law, means fulfilment of a contract or decree of the court.

IMPLEMENTS, AGRICULTURAL. Under this term are generally comprehended not only the implements used in the actual cultivation of the soil, but those requisite for other operations of farming, and for the preparation of the produce of the land for use, in so far as it is ordinarily carried on by the farmer. The first implements for the cultivation of the ground were doubtless such as could be used by man's unaided strength, and many such are still in use, as the spade, the hoe, the fork, and the shovel. When animals were reduced to the service of man, the plough appeared in its first rude form. Grubbers, cultivators, &c., are recent inventions; rollers are more ancient. Sowing machines or drills are modern, but the harrow is ancient, although branches of trees drawn along the newly sown land, long served the purpose of its now carefully adjusted tines. The necessity of irrigation in some countries early led to expedients and implements for accomplishing it. The Egyptian shadow is figured in the article AGRICULTURE. Implements for clearing the ground of weeds, for occasional stirring of the ground whilst under crop, and for currying up crops, are all, except the hoe, of comparatively recent invention. The scythe and sickle have existed from remote antiquity, although the reaping-machine is a novelty only beginning to assume a very important place. Wheel-carriages of various descriptions and for various purposes must be mentioned among agricultural implements; also implements for threshing and winnowing corn, for scutching and breaking flax, for ginning cotton, for crushing sugar-cane and evaporating its juice, &c.
The preparation of the produce of different plants requires implements of different kinds. Others are required in the care of cattle, and for the Dairy (q.v.). The principal agricultural implements are noticed in separate articles, and some in connection with particular kinds of cultivated plants.

IMPLUVIUM, a tank or cistern in the centre of the hall or Atrium (q.v.) of a Roman house. In the examples which remain at Pompeii, the impluvium is generally formed of marble. It is placed immediately under the unroofed part of the atrium, and is intended to receive the rain which runs down from the roof through the opening. The impluvium was frequently adorned with fountains, and formed a very peculiar and interesting feature in the dwellings of the Romans.

IMPOUNDERABLE SUBSTANCES, an epithet applied to light, heat, electricity, and magnetism, at a time when they were universally considered as matter, in contradistinction to those substances which possessed sensible weight. See HEAT.

IMPORTS AND EXPORTS. See Balance Of Trade.

IMPOST, the point where an arch rests on a wall or column. It is usually marked by horizontal mouldings, but sometimes these are absent, especially in Gothic architecture, where different forms of impost are used. These have been classed by Professor Willis as—1st, the continuous impost, where the arch mouldings are carried down the pier; 2d, the discontinuous impost, where the arch mouldings abut and are stopped on the pier; 3d, the shifted impost, where the arch mouldings spring from a capital, and are different from those of the pier—the form used in the best Gothic; 4th, the banded impost, where the pier and arch have the same mouldings; but the impost is marked by a band of horizontal mouldings, as is frequently the case in Italian-Gothic buildings. These simple forms of impost are sometimes used together, so as to produce more complex combinations.

IMPOTENCY, in Law, is a good ground for either of two married parties annulling the marriage, if the impotency existed at the time the contract was entered into. The defect must be proved. The law is uniform in the United Kingdom.

IMPOUNDING A DOCUMENT occurs when a document is produced in course of a trial or hearing before a court or judge, who, instead of giving it up to the owner, retains it, in order to enable a prosecution to be brought if necessary.

IMPOUNDING CATTLE is, in English Law, the remedy given to all occupiers of land against the cattle of strangers which stray on such land. It amounts, in fact, to taking and keeping the cattle as a security for the damage which has been done. The occupier is then said to drain the cattle damage feinds. He is then entitled to driving them in the nearest pound, if there is one within three miles—i.e., an enclosed place kept for the purpose—or he may put them in premises of his own. In either case, he is bound to feed and water the cattle at the expense of the owner of such stray cattle, who can only recover them back by paying these expenses and the damage done, or on giving security, and bringing an action of Replevin (q.v.) to try the right. The cattle cannot be distressed unless they are at the time actually trespassing upon the land. In Scotland, a similar right exists, called the pointing of stray cattle.

IMPRESSION was once the mode formerly resorted to of manning the British navy. The
IMPRISONMENT – IMPROVISATORI

practice had not only the sanction of custom, but the force of law, for many acts of parliament, from the reign of Philip and Mary to that of George III., had been enacted to regulate the system of procrastination. But imprisonment consisted in seizing by force, for service in the royal navy, seamen, river-watermen, and at times landmen, when state emergencies rendered them necessary. A seaman could be made a privateer, or a pay officer, usually proceeded to such houses in the seaport towns as were supposed to be the resort of the seafaring population, laid violent hands on all eligible men, and conveyed them forcibly to the ships of war in the harbour, and, as not in the nature of sailors to yield without a struggle, many terrible fights took place between the press-gangs and their intended victims—combats in which lives were often lost. In point of justice, there is little, if anything, to be said for imprisonment, which had not even the merit of an impartial selection from the whole available population.

In recent times, when volunteers fail, a system of impressment has been resorted to; and it is not very probable that recourse will be again had to imprisonment. At the same time, the laws sanctioning it slumber, without being repealed.

Under the laws, all eligible men of seafaring habits, between the ages of 18 and 55, but exemptions are made in favour of apprentices who have not been two years apprenticed, fishermen at sea, a proportion of able seamen in each collier, harpooners in whalers, and a few others. A press-gang could board a merchant- vessel or a privateer on its own nation in any part of the world, and carry off as many of the best men as could be removed without actually endangering the vessel. The exercise of this power made a privateer dread a foolishly stationed guard, and war more than had led to exacting a chase as when enemies were in pursuit of another; for the privateer's men were the best sailors, for their purpose, the naval officers could lay hold on.

IMPRISONMENT. The power of imprisonment for non-payment of debt, as well by way of punishment for crime, has always been held to be inherent in courts of justice. In criminal proceedings also, a person may, by a warrant of arrest, be imprisoned prior to a trial, provided the justice considers it not a proper case for allowing bail; and as a general rule, though in minor offences an accused person may insist on being bailed, the practice of bailing men charged with major crimes is more in the discretion of the justice to accept or refuse the bail tendered, and on his refusal, application may be made to judges of the common law courts to accept bail. As regards imprisonment for debt, it is now competent only in cases where judgment has been obtained, and the debt is £20 or upwards. In one case, however, and one only, a person may be imprisoned before judgment has been obtained—viz., where he is about to leave the kingdom. In such a case, the creditor requires to make an affidavit of the debt or cause of action before a judge, and may obtain a capias to arrest the defendant, who will not be released till the judgment is obtained. With regard to debts under £20, which are generally sued for in England in the county court, though the defendant cannot be imprisoned on a judgment for less than that amount, yet if he willfully disobey the judgment of the court, which ordered him to pay by instalments or on a time certain, and if the debt was originally contracted by means of fraud, the judge can commit him for contempt, and thus imprison him on another ground. In cases of insolvency, if a person allow himself to be taken to prison for debt, and remain in prison for fourteen days if a trader, or two months if a non-trader, this is an act of bankruptcy, and he may be adjudged bankrupt, and his goods distributed in the usual way by the Court of Bankruptcy, but in general if a person wishes to be made a bankrupt, he can become so without the necessity of being imprisoned. It is also a doctrine of the law of England, that if a debtor is once imprisoned for debt, it operates as complete satisfaction, and his land or goods cannot in that case be taken. But the debtor can only get out of prison through the intervention of the Bankruptcy Court, which requires him to give up everything to the creditors.

In Scotland, imprisonment for debt is also competent on similar principles; and it is competent to imprison a debtor if the debt exceed £12. An absconding debtor may also be arrested if in meditations fugae—i.e., about to leave the country, in which case bail or caution is required. In Scotland, imprisonment for debt is not considered satisfaction of the debt, and the creditor may at the same time possess his goods and adjudge his land, and take other concurrent remedies.

IMPROBATION, a Scotch law-term, meaning the disproving or setting aside a deed on the ground of falsehood or forgery.

IMPROMPTU, in music, a short extemporaneous composition. See also FANTASIA.

IMPROPRIATION, the transfer of a layman of the revenues of a benefice to which the cure of souls is annexed, with an obligation to provide for the performance of the spiritual duties attached to the benefice. The practice of improprigation differs from the mere payment of a sum of money for the performance of a religious service, as the latter is a case of appropriation, inasmuch as the latter supposes the revenues of the appropriated benefice to be transferred to ecclesiastical or quasi-ecclesiastical persons or bodies, as to a certain dignitary in a convent, a college, a hospital; while improprigation implies that the temporalities of the benefice are enjoyed by a layman; the name, according to Spelman, being given in consequence of their thus being improperly applied, or diverted from their legitimate use. The practice of improprigation, and still more that of appropriation, as in the case of monasteries, &c., and other religious houses, prevailed extensively in England before the Reformation; and on the suppression of the monasteries, all the suppressed revenues (by 27 Henry VIII. c. 28, and 31 Henry VIII. c. 13) vested in the crown, and were by the crown freely transferred to laymen, to whose heirs they descended not only the right to tithes, but also in many cases the entire property of rectories. The spiritual duties of such rectories are discharged by a clergyman, who is called a vicar, and who receives a certain portion of the emoluments of the living, generally consisting of a part of the glebe-land of the parsonage, together with what are called the 'small tithes' of the parish.

IMPROVING LEASE, a lease, in Scotland, by which the tenant undertakes to keep the premises in repair; called a repairing lease in England.

IMPROVISATORI, an Italian term, designating poets who utter verses without previous preparation on a given theme and who accompany their voice with a musical instrument. The talent of improvisation is found in races in which the imagination is more than usually lively, as in Corsica and in many tribes of negroes. Amongst the ancients, Greece was particularly noted for improvisation. In modern Europe, it has been almost entirely confined to Italy, where Petrarch, in the 13th c., introduced the practice of singing improvised verses to the lute; and down to the
Present day, the performances of improvisatori constitute one of the favourite entertainments of the Italians. Females (improvvisatrici) have frequently exhibited this talent in a high degree. Improvisation is by no means limited to brief poems of a few verses and of very simple structure, but is often carried on with great art, and in the form and to the length of a tragedy or almost of an epic poem. But when the productions of the most admired improvisatori have been given to the world through the press, they have never been found to rise above mere mediocrity. It is worthy of notice that the greater number of the celebrated improvisatori of Italy have been born in Tuscany or the Venetian territories. Siena and Verona have been especially productive of them. Some of the principal are: Serafino d'Aquila (died 1500), Metastasio (q. v.), who soon abandoned the art, Zucco (died 1764), Serio and Ross (beheaders at Naples, 1799), Gianni (pensioned by Bonaparte), and Tommaso Sgricci (died 1836). The best-known improvvisatrici are Magdalena Moralli Fernandez (died 1800), Teresa Bandettini (born 1756), Rosa Taddei (born 1801), and Signora Mazzei, the last of whom is probably the first point of talent.

Impulsive Madness. The approaches of mental disease are generally slow and insensible; but instances occur where, without announcement, without any preliminary stage of disease or disturbance, an individual, apparently hitherto of sound mind, is suddenly seized with mania, presents symptoms of uncontrollable violence, perpetrates acts of atrocity or absurdity, altogether inconsistent with his previous disposition and deportment; and then, nearly as quickly, subsides into his ordinary state and habits, retaining no, or a very imperfect, recollection of the events which occurred during the paroxysm. It is not, however, in the suddenness or shortness of the paroxysm that the essential characteristic consists. During the continuance of such an affection, three mental conditions are distinctly traced: 1. The sudden birth and irresistible dominion of a propensity; 2. The abolition or impairment of the apprehension of the real and ordinary relations of the individual; and 3. The suspension of the powers by which such propensities may be prevented from arising, or ruled and regulated when they do arise. Alienation of this kind has been chiefly recognised when the instincts are involved; and the most striking illustrations are derived from cases of diabolical or sanguinary passion. The simplicity of the results may convulse society, or come under the notice of courts of law. But many examples exist of brief periods of aberration which could not be ingrained by passion, and involved nothing criminal. A lady is mentioned who never entered church but she was impelled to shriek, or saw plate-glass but she was impelled to break it; and the incongruous laughter, the grotesque gestures, and the involuntary and repulsive associations to which good and great men have been subject, must all be placed under this category.

Imputation is one of the most common technical expressions in Christian theology. It is meant to denote the transference of guilt or of merit of punishment or reward. The doctrine of the imputation of sin, for example, is the doctrine which, therefore, has been never found to rise above mere mediocrity; and the correlative doctrine of the imputation of Christ's righteousness is that which inculcates that the merit or righteousness of Christ is transferred to those who believe in Him, or, in other words, that they become sharers in His merit or righteousness. This idea of transference of intercommunication of good and evil, is a pervading one in Christian theology, and answers to unchallenged realities of the spiritual life; but the idea is also apt to become degraded and materialised, and has become so in some of its common representations in popular theology. The doctrine of the imputation of Adam's sin, for example, expresses the idea, and even in cases of participation of the human race in the consequences of Adam's transgression, so that, because he sinned and fell from innocence, they, the inheritors of his corrupt nature, also sin, and are involved in the miseries of a sinful state; but, moreover, the idea, that the sin of Adam in its direct guilt and wickedness is transferred to his posterity. They reason after this manner: it is undeniable that man suffers on account of original sin; but suffering and sin are in separably connected. If man suffers on account of original sin, therefore, it is only because he is guilty of it. The sin of Adam in eating the forbidden fruit is equally the sin of his posterity. According to this mode of reasoning, therefore, is a fundamental idea of the sin of Adam to all his descendants. God is supposed, as it were, to charge the one to the account of the other, and by a direct and arbitrary act, to hold mankind guilty because Adam fell. To give a logical justification to this view, it is assumed that God entered into a covenant with Adam (see Covenant), by which the latter was regarded as a representative of the whole human race; so that when he fell, all mankind, sinned and fell with him. In the same manner, the merit or righteousness of Christ is supposed to be imputed to believers by a direct and formal transference of the one to the account of the other. In both cases, it is the idea of formal and arbitrary exchange that is prominent; and according to some theologians, this idea alone answers to imputation of sin or of righteousness. To impute sin, is to deal with a man as a sinner, not on account of his own act, or at least not primarily on this account, but on account of the act of another; and to impute righteousness, is to deal with man as righteous, not because he is so, but on account of the righteousness of Christ reckoned as his, and received by faith alone. The act of another stands for our own act, and we are adjudged—in the one case condemned, in the other acquitted—not for what we ourselves have done, but for what another has done for us. This is a fair illustration of the tyranny which technical phrases are apt to exercise in theology as in other things. When men coin an imperfect phrase to express a spiritual reality, the reality is apt to be forgotten in the phrase, and men play with the latter as a logical counter, having a force and meaning of its own. Imputation of sin and imputation of righteousness have in this way come to represent legal or pseudo-legal processes in theology, through the working out of the mere legal analogies involved by the word, that the real spiritual reality which lies behind the phrases in both cases is simple enough. Imputation of sin is, and can be nothing else than the expression of the spiritual unity of Adam and his race. Adam 'being the root of all mankind,' the stock which has grown from this root must share in its degeneracy. The law of spiritual life, of historical continuity, implies this, and it requires no arbitrary or legal processes, to account for the race of mankind as derived from a sinful source. We are sinners because Adam fell. The fountain having become polluted, the stream is polluted. We are involved in his guilt, and could not help being so.
by the conditions of our historical existence; but, nevertheless, his sin is not our sin, and cannot in the strict sense be imputed to us, for sin is essentially voluntary in every case—an act of self-will, and not a mere quality of nature; and may sin, therefore, cannot be another's, nor another's mine. In the same manner, the highest meaning of the imputation of the righteousness of Christ lies in the spiritual unity of the believer with Christ, so that he is one with Christ, and Christ one with him, and in a true sense he becomes a partner of the divine nature. The notion of legal transference is an after-thought—the invention of polemical logic—and the fact itself is deeper and truer than the phrase that covers it. The race one with Adam, the believer one with Christ, are the ideas that are really true in the phrases imputation of sin and imputation of righteousness. The logic of theology has evolved many more applications of the phrases, but these applications are rather the refinements of theological pedantry than the expression of true spiritual relations.

IN ARTICULO MORTESi, a phrase used in Scotland to denote a deed executed on death-bed. As a general rule, such a deed, in Scotland, operating like a will, may be set aside by the heir-at-law. But a will in England having the same effect cannot be set aside on that ground.

INAGUA, GREAT and LITTLE, are the two most southerly islands of the Bahama group, the former of which, measuring fifty miles by twenty-five, is remarkable for having its longer dimension placed almost at right angles to those of the rest of the cluster. The Little I. lies about twelve miles north, and measures eight miles by six. In 1851, the population of both islands together was 530, of whom 54 were white.

INANITION. See Starvation.

INCANCING, or GRAFTING BY APPROACH, a mode of grafting by which branches are united together before any of them is separated from its original stem. Branches growing across one another sometimes unite in this way of themselves, and it is supposed—not improbable—that an observation of this circumstance first led to the invention of grafting. Incarching is practised in cases in which the ordinary mode of grafting are not found ready to succeed, as with camellias. The stocks to be grafted upon are planted, or placed in pots, around the plant from which the grafts are to be taken. Four or five months are generally sufficient to complete the union, but sometimes even two years are necessary. When the union is complete, the scion is separated by a sloping cut from its parent plant. Care must always be taken that the parts to be joined together be cut so as to fit one another pretty exactly, and they are then firmly tied together, and so covered that neither air nor water may penetrate. It is desirable that they be branches of nearly the same thickness. They should thus be cut square to the path, but the pit must not be injured. Incarching is performed in spring, after the sap has begun to circulate. The accompanying figure illustrates several ways of incarching. For example, two branches of a tree, a, may be bent together in such a manner, so as to cover their main stem, by which a gap will be filled up; one growing tree, b, either from the ground or a pot, may be led to unite with another; or several suckers, c, may be led from the ground archwise to strike upon a point in the stem, thus bringing fresh aid to the productive part of the tree. By means such as these, quickset-hedges are sometimes thickened like a network, so as greatly to improve their appearance and protective qualities.

IN CAEFA DOMINI, a celebrated papal bull, so called from the ancient day of its annual publication on Holy Thursday. It is not, as other bulls the work of a single pope, but with additions and modifications at various times, dates back from the middle ages; some writers tracing it to Martin V, others to a Scottish pope—Reginald de Longueville. Its present form, however, it received from the popes Julius II., Paul III., and finally Urban VIII., in 1627, from which year it continued for a century and a half to be published annually on Holy Thursday. The contents of this bull have been a fertile subject of controversy. It may be briefly described as a summary of ecclesiastical censures, especially of those with which grievous violation of the faith of the church, or of the rights of the church or of the Roman see, are visited; excommunication being denounced against heresy, schism, sacrilege, usurpation of the rights of the church or of the pope, forcible and unlawful seizure of church property, personal violence against ecclesiastics, unlawful interruption of the free intercourse of the faithful with Rome, &c. The bull, however, although mainly dealing with offences against the church, also denounces under similar censures other crimes, as piracy, plunder of shipwrecked goods, forgery, &c. This bull being revoluted by most of the heads of Europe as an infringement of their rights, encountered in the 17th c. the determined opposition of nearly all the courts, even the most Catholic; and that is the reason of its later publication. It came out in 1670, 112 years after its publication, which has never since been renewed.

INCASCATION, like exsaut, is derived from a Latin root meaning simply 'to sing;' as chora is only a disguised form of cormen, a song. It is the term in use to denote one of the most powerful and awe-inspiring modes of Magic (q. v.), viz., that resting on a belief in the mysterious power of words solemnly conceived and passionately uttered.

There is in the human voice, especially in its more lofty tones, an actual power of a very wonderful kind to stir men's hearts. When to this we add that there is an immediate power is a special and very strong mode of solicitation; that the language of primitive nations is crude and unmanageable, the words being as difficult to weld together as pieces of cast iron; that it is only when the poet's mind has risen to unusual height that he can fuse them into those rhythmical sequences that please the ear and hang together in the memory; that, in short, his art is a mystery to himself—his inspiration; we need not wonder at the feeling with which everything in the form of verse or metre was viewed.

The singing or saying of such compositions, which could thus stir the blood of the hearers, they knew not how, what other effects might it not produce?
INCARNATION—INCEST.

Accordingly, there is no end to the power ascribed to incantations, especially when accompanied, as they generally were, with the concocting of drugs and other magical rites. They could heal or kill. If they could not raise from the dead, they could make the dead speak, or 'call up spirits from the vasty deep,' in order to unveil the future. They could extinguish fire; darken the sun or moon; make letters burst, a door or a mountain fly open; burst a sword into powerlessness; destroy a crop, or charm it away into another's barn. The prayers of heavenists, whether for blessings or for causes, partake largely of the nature of magical incantations. They are not supposed to act as petitions addressed to a free agent, but by an inherent force which even the gods cannot resist. This notion is very prominent in Hindustan and Buddhism; but it more or less disguises pervades all superstitions. They think they shall be heard for their much speaking.

For almost every occasion or operation of life, there were appropriate formulas to be repeated in order to secure success; and many of these, with that reverence for antiquity and conservative tendency which always characterise superstition, continue to live in popular memory, although often the words are so old as to be unintelligible. The Romans, in the days of Cato, used incantations, for curing diseases, full of words which had been lost. A form of words used this day in Shetland for healing a sprain can be traced back to the 10th century. In its earliest form, as found in old German manuscripts, it states how Woden and Baldur rolling out to hunt, Baldur's horse displaced its foot, and how Woden, using charmed words, set bone to bone, &c., and so healed the foot. The repetition of this rhymed narration acted as a charm to heal other lamed horses. The modern version of this tradition, as current in Norway, makes the accident happen to the horse of Jesus, and Jesus himself perform the cure. In Shetland, also, it is the Lord, meaning Jesus, that is substituted for the woven word; and the formula is applied to the healing of persons' limbs as well as those of horses. The operation is thus described in R. Chambers's Popular Rhymes of Scotland: 'When a person has received a sprain, it is customary to apply to an individual practised in casting the 'wresting thread.' This is a thread spun from black wool, on which are cast nine knots, and tied round a sprained leg or arm. During the time the operation is putting the thread round the affected limb, he says, that in such a tone of voice as not to be heard by the bystanders, nor even by the person operated upon:

Our Lord rade,  
His foal's foot slade;  
Down be lighted,  
His foal's foot righted.  
Bone to bone,  
Sign to sign,  
Blood to blood,  
Flesh to flesh.

Heal, in name of the Father, Son, and Holy Ghost.'

INCARNATION (Lat. in, and caro, carnis, flesh), a term much used in theology concerning the union of the divine nature of the Logos with human nature in the person of Christ. We read in John, i. 14, that 'the Word was made flesh;' but this is understood not as signifying a change of nature, but an assumption of human nature, of personal union with the divine nature. In accordance with Luke, i. 30, and other texts of Scripture, the formation of the human nature of Christ is ascribed to the Holy Ghost. The reality of the human nature of Christ was much disputed in the first ages of Christianity, but in our times the chief dispute as to the person of Christ relates to his divine nature. Whilst the doctrine of the incarnation is generally asserted by all who profess Christianity, except Unitarians (q.v.), no explanation of it is attempted or deemed possible. It is regarded, however, as a doctrine fraught with most important consequences, affecting the whole system of Christianity. In the doctrine of the incarnation, it is maintained that in union with the person of the Son of God, there was, and is, in the person of Christ, not only a true human body, but a human 'reasonable' soul.

INGAS. See PERU.

INCENDIARY LETTER, a letter threatening to burn the house or premises of a person, generally called a threatening letter. To send such a letter is felony, punishable by three years' penal servitude. The offence is punishable in Scotland according to the discretion of the court.

INCENDIARY SHELLS, another name for Carcasses (q.v.).

INCENSE (Heb. mukter, koter, and kitteroth), a perfume, the odor of which is evolved by burning, and the use of which, in public worship, prevailed in most of the ancient religions. The incense at present in use consists of some resinous base, such as gum olibanum, mingled with odoriferous gums, balsams, &c., and is usually burnt in some regular manner for incense, almost every maker having his own peculiar recipe. The ingredients are usually olibanum, benzoin, styrax, and powdered cassarilla bark. These materials, well mingled, are so placed in the censer or shrubbile as to be sprinkled by falling on a hot plate, which immediately volatilises them, and diffuses their odour through the edifice.

Among the Jews, the burning of incense was exclusively employed as an act of worship, and, indeed, would appear to have been in itself regarded in the light of a sacred offering. The same would also appear for the religion of Egypt; but the Persian sculptures exhibit the burning of incense as one of the marks of honour offered to royalty.

In the Catholic Church, both of the West and of the East, incense is used in public worship, more particularly in connection with the Eucharistic service, which is regarded as a sacrifice; but writers are not agreed as to the origin of its use. Its use can be traced. St Ambrose, in the Western Church, alludes to incense in terms which suppose the practice of burning it to be an established one; and in later writers, it is mentioned familiarly as a part of ordinary public worship. In the Roman Catholic Church, incense is used in the solemn (or high) mass, in the consecration of churches, in solemn consecrations of objects intended for use in public worship, and in the burial of the dead. There are also minor incenseries of the celebrating bishop or priest and inferior ministers; of prelates, princes, and other dignitaries officially present at the public service, and a general incensation of the whole congregation.

In the Reformed churches, the use of incense was abandoned at the same time with other practices which have been laid aside by them as without 'warrant of Scripture.'

INCENSED, or ANIMÉ, an epithet applied in Heraldry to pendants or other wild beasts borne with flames issuing from their mouths and ears.

INCEST (Lat. in, not; natura, nature) is the marrying of a person within the Levitical degrees. In the old ecclesiastical law (now obsolete), and in Scotland, it comprehends cohabitation irrespective of marriage. The law of England enforced these prohibitions by
several statutes in the reign of Henry VIII., which are still in force. Recent cases have determined that a marriage by consent between a widow and his deceased wife's sister comes within these rules, and is void, and it makes no difference that the marriage was celebrated in a foreign country, as, for example, Denmark, where these marriages are legal, provided the parties were domiciled in England, and went there merely to evade the English law. It has also been decided in England, that the same rules which apply between legitimate relations apply between natural relations, though one illegitimate—as, for example, between a man and the daughter of an illegitimate sister of his deceased wife. Though incestuous marriages are utterly void in England, still it is not a criminal offence to marry incestuously, not even in those cases in which the connection is most abhorrent to the moral sense of mankind, and the remedy in the ecclesiastical courts may be considered obsolete. In Scotland, incest, which is calculated on the same grounds, not only makes a marriage void, but the better opinion is, that to marry incestuously, as well as to commit incest, is a capital offence. See MARRIAGE.

INCH, a Gaelic word, corresponding to Irish iona, and signifying Island (q.v.): the same root appears in the Danish isla. Inanc and isolenter enter into many compounds, as Incheolin (q.v.), Immiscatery, an island in the estuary of the Shannon.

INCHCOLM (of old, 'St Colm's Inch,' as in Shakespeare's Macbeth, act i. sc. 2; in Lat. Aemonia, and insula Sancti Columbi), an island, beautifully placed in the Firth of Forth, within sight of Edinburgh. It is separated from the north or Fife shore by a channel less than a mile broad, called 'Mortimer's Deep.' The isle is somewhat more than half a mile in length, and less than a third of a mile broad where widest. It had a population in 1861 of 7. It takes its name from St Colm or Columba (q.v.) of Iona, who is said to have dwelt here while labouring for the conversion of the Northern Picts in the 6th century. In the year 1125, King Alexander I. of Scotland, being shipwrecked upon it, found it inhabited by a solitary hermit, who lived on shell-fish and the milk of one cow, and served St Columba in a little chapel or oratory. The king, in gratitude for his escape, founded on the island an abbey of Augustinian Canons. Walter Bower, the engraver and continuator of the Scotichronicon of John of Fordun (q.v.), was abbot of the monastery from 1418 till 1449. It was repeatedly sacked by the English during the 14th, 15th, and 16th centuries. The buildings, which have long been in ruins, shew traces of Romanesque work (of about the middle of the 12th c.); but are chiefly First Pointed (of the 13th and 14th centuries). The tower has some resemblance to the tower of Iona. The oldest edifice is a little vaulted oratory (20 feet long by 7 broad), believed to represent the chapel in which King Alexander found the anchorite serving St Columba in the 12th century. It is of the same type as the oratory of Galleus. It has been lately restored. The history of L has been written with great detail by Professor Simpson, in the Proceedings of the Antiquaries of Scotland, vol. ii. pp. 489—524. The chartulary of the abbey is about as. 1/2 of the Mainland C.

INCHEKEITH, an island in the Firth of Forth, midway between Leith and Kirkcosh. It is a mile in length, and not much more than a third of a mile broad where widest. Its population in 1861 was 12. It is believed to be the site of the town or streets discribed byaland by! who wrote about 731 A.D. as situated in the middle of the great arm of the sea which runs into Britain from the east (that is, the Firth of Forth). From the island fortress of Gisli, the inlet in which it stood, was of old called 'the sea of Gisli,' and hence also, probably, I. took its name. The island is said to have been the site of a church or monastery, founded between 679 and 704 A.D. by St Adamnan, the biographer of St Columba, and his successor in the abbacy of Iona. I. was seized by the English in 1547, when they built a fort, which, in 1549, was taken by the French auxiliaries of Scotland, who gave the island the name of the 'Isle of Horses.' A light-house was built on the site of the fort in 1804. The island, which belongs to the Duke of Buccleuch, is part of the parish of Kinghorn, in Fife.

INCIDENCE, ANGLE OF. See CATEPTICS.

INCIDENT DILIGENCE. In Scotch Law, letters of incident diligence are issued to compel the attendance of witnesses and havers at a trial. In England, a subpoena and a subpoena duces tecum are similar writs.

INCIPTITUR, in English Law, the formal commencement of a judgment in a common law court.

INCLINED PLANE, The, is reckoned one of the Mechanical Powers (q.v.), because, by rolling an object up a plane, a man may raise a weight which he could not lift. This principle is extensively made use of, chiefly in the raising of weights and in road-making. It is here unnecessary to go into a minute investigation of the theory of the inclined plane, as it may be seen in the common books on mechanics, but the result is as follows: The force required to lift a body (viz., its weight) bears to the force required to keep it from sliding down the plane the proportion that the length of the inclined plane bears to its height; also the weight of the body bears to the weight which tends to bend or break the inclined plane, the same proportion that the length of the plane bears to its base. Let us suppose a plane, whose length, AB, is thirteen feet; base, AC, twelve feet: height, BC, five feet; and let the weight be 780 pounds. Then the force F, which may sustain the weight, is 780 pounds on the inclined plane, is 1/3ths of 780, or 300 pounds (i.e., a force which could just lift 300 pounds); also the force R, which presses perpendicularly on the plane, is 1/3ths of 780, or 720 pounds. When the weight has not only to be sustained on the plain but drawn up it, the resistance of Friction (q.v.) has to be added to the power necessary to sustain the weight. In common roads, engineers are agreed that the height of an incline should not exceed 1/5th of the length, or, as they phrase it, the gradient should not be greater than one in five. It may here be mentioned that knives, chisels, braces, and screws, are merely modifications of the inclined plane, but the last two being generally classified as distinct mechanical powers, will be treated each under its own head.

INCOMBUSTIBLE FABRICS have of late years become of great importance, owing to the terrible frequency of death from the ignition of clothing; the search, however, after some means of rendering garments incombustible has continued from a very early period (see Beckmann's History of Inventions). The first attempt in this direction was made by Guy Lussac and other chemists, Mesar
INCOME-TAX—INUNCABULA.

Vermann and Oppenheim communicated to the British Association, at Aberdeen in 1859, the results of a series of experiments for rendering linen, calico, muslin, and all other vegetable fibres infinammatible.* They found that many salts possessed this power, but at the same time some of these injured the material in some degree. Borax, for instance, is very expensive, as to render their general use impossible. Two, however, viz., tungstate of soda and sulphate of ammonia, produced the best results without injuring the colour of the fabric. The first of these acts physically by preventing contact with the air, and does not interfere with the processes of ironing and starching; it is therefore preferable for goods requiring washing. The best method of applying it is by mixing in the proportion of 4 ounces of tungstate of soda to 1 drachm of phosphate of soda (to prevent the formation of a partially insoluble bi-tungstate), and dissolving the whole in an imperial pint of water. For fabrics which are worn without previous washing, sulphate of ammonia is preferable, and a solution containing 7 per cent. of the crystalline salt is a perfect preservative. In printed muslins of a madder purple, however, a slight paleness is produced, which in no other case is the colour affected, nor does it interfere with the ironing process. It is to be hoped that these simple and efficacious preservatives will soon come into general use.—The incombustible fabrics of the Egyptians were formed of Asbestos (q. v.).

INCOME-TAX, a tax imposed on all persons having incomes above £100, whether from lands or labour. Various acts have passed from time to time to impose this tax—the first introduced by Pitt, and latterly revived in 1842 by Sir Robert Peel, since which date it has been continued—the fairness and public policy of which have given rise to long and endless controversy. See TAXATION.

INCOMMENSURABLE MAGNITUDES, or INCOMMENSURABLE QUANTITIES, are those which have no common measure, i.e., are not both of them, multiples of the same unit, however small that unit may be taken. Examples of incommensurable magnitudes are abundant in mathematical science. Thus, the side and diagonal of a square; the diameter and circumference, or diameter and area, of a circle, &c.; \( 2 \) and \( \sqrt{2} \); \( 3 \) and \( \sqrt{3} \), &c. The term incommensurable magnitudes is used in arithmetic to denote two numbers which have no common measure greater than unity.

INCORPORATIONS. See CORPORATIONS.

INCORPORAL HEREDITAM. See HEREDITAM.

INCUBATION, The Period of, or the duration of the time in which birds sit on their eggs before the young are hatched, varies in different species, and is nearly constant in each. In the humming-birds, the smallest animals of this class, it is only 12 days; in canaries, it is from 15 to 18 days; in the common fowl, it is 21 days; in the duck, it is from 28 to 30 days; in the guinea-fowl, it is 28 or 29 days; in the turkey, 30 days; and in the swan, from 40 to 45 days. A certain degree of heat (about 104°) is necessary for the development of the young bird; that of the sun is sufficient, during the day, to hatch the eggs of some birds (for example, the ostrich) including tropical countries, but in general the mother keeps up a suitable temperature by placing the eggs in a warm and carefully constructed Nest (q. v.), and by covering them with her own body. In some cases, the male bird takes part in this duty; usually, however, his services are restricted to providing his mate with food.

Eggs may, however, be hatched without the aid of the parent bird. From time immemorial, the Egyptians have hatched eggs by artificial warmth, using in peculiarity an apparatus called "bombsa." In 1777, Mr. Bonenvein devised an apparatus by which, for several years before the French Revolution, he supplied the Parisian markets with excellent poultry, and with a profit. At a period when the farmers had ceased to supply it. A description of this apparatus is given in Mr. D'Arcet's Dictionary of Arts, &c., 5th ed. 1860, vol. ii. p. 498.

The process of artificial incubation was publicly exhibited some years ago in London, by means of the Eckelodien machine (derived from Eckel, I call forth, and bion, life), which was invented by Mr. Bucknell, and is described in his Treatise on Artificial Incubation. This machine possessed a perfect control over temperature from 30° Fahrenheit to that of cold water for any length of time, and 'by means of this absolute and complete command over the temperature, the impregnated egg of any bird, not the colour, placed within its influence at the proper degree of warmth, is, at the expiration of a certain time, elicted into life, without the possibility of failure.' That chickens were hatched in large numbers by this machine is undoubted, but for some reason it has not rendered itself economical for commercial purposes—the Eckelodien has not been lately heard of.

In 1825, M. D'Arcet obtained chickens and pigeons at Vichy by artificial incubation effected by the thermal waters of that place.

INCUMBENT, the rector, parson, or vicar holding an ecclesiastical benefice in England or Ireland. It is seldom used in Scotland except popularly in a similar sense.

INCUMBREANCES, a general term for burdens or charges on land. See HERITABLE SECURITIES, MORTGAGES, LIENS.

INCU'NABULA, a Latin word signifying cradle, is employed by bibliographers to designate the first fruits of the art of printing; the books which, as Peignot has it, touchent au berceau de l'imprimerie. The term is usually restricted to those which appeared before the year 1500, by which time the art was completely formed in all its principal departments. The number of these works is probably not far short of 20,000. Hain, it is true, in his Repertorium Bibliographicum, enumerates only 16,293; but as he unfortunately died before his work was completed, it is confessedly imperfect, especially in the last volume.

Incnabula, with hardly any exceptions, belong to the category of rare books, and are therefore much sought for by collectors; but besides the interest attaching to them as literary curiosities, many of them, such as the first editions (editions princeps) of the Greek and Roman classics, are intrinsically valuable in a critical point of view; whilst others are important, as marking the successive steps by which the art of printing advanced towards perfection. Information as to these particulars will be found in the article PRIVY PRINTS.

The principal works treating specially of incnabula are—Panzer, Annales Typographici, ob Artis Incunabularia ad Annam M.D. (continued, however, to 1536), 11 vols. 4to, Norimbega, 1793—1863; Montfaucon, Annales Typographici, ob Artis Incunabularia ad Annam 1557 (cum Appendice ad Ann. 1604), 3 tom. in 5 vols. 4to, Haga-Comit. 1719—1725; Serna Santander, Dictionnaire Bibliographique Chinois du XVe Siècle, 3 tom. 8vo, 331.
INDEBITATUS ASSUMPSIT—INDEPENDENTS.

Brussels, 1845—1807; and Hain, Repertorium Bibliographicum, quo Libri nonus ab Arte Inventa notae ac M. D. Tupis Exempli recensemer, 4 tom. Svo, Stuttgart, 1828—1838. With all its imperfections, the last is the best work we have on the subject. Much valuable information, conveyed in a pleasing and attractive style, will also be found in Bernard, De L'Origine et des Debates de l'Imprimerie en Europe, 2 tom. Svo, Paris, 1833.

INDEBITATUS ASSUMPSIT, the name often given to an action for debt in England.

INDECENT EXPOSURE is a criminal offence both at common law and in England and Ireland also by statute. It is not clearly settled whether more than one person must have witnessed the indecency, in order to make it an offence. The exposure must be in some public place. By the statute 5 Geo. IV. c. 83, s. 4, the offence is punishable summarily by three months’ imprisonment. To sell or expose an obscene book, print, or picture, is also punished by the statute under the same element of hard labour; and a warrant can be obtained under 20 and 21 Vict. c. 83, to search premises, and seize and destroy such books, &c. In Scotland, indecent pictures are also indictable offences, but the last is somewhat vague, and the punishment left to the discretion of the court.

INDEMNITY DEED, in English Law, is a deed given by way of security. The usual form of indemnifying a person is by giving a bond of indemnity, which operates if the engagement is not fulfilled, but otherwise becomes void. A similar bond is called generally a bond of relief in Scotland.

INDENTED, in Herably, one of the partition lines of the shield, similarly notched to Dancetté (q. v.), but with the notches much smaller, and not limited in number.

INDENTED HEAD, a peninsula in the colony of Victoria, bounds the entrance to Port Phillip on the west.

INDENTURE, the technical name given in England to a deed under seal, entered into between two or more parties with mutual covenants. Formerly, it required to be actually indented—i. e., notched or toothed (Lat. dent, tooth), or cut in a waving line, so as to correspond with the other copy of the deed—but this is no longer necessary. The indented head is still used in a general way in Scotland, except in the case of indentures of apprenticeship (q. v.), though in England it is a synonym for the kind of deeds mentioned.

INDEPENDENTS, or CONGREGATIONALISTS, are a sect of professing Christians, supposed to have originated in England about the year 1583. A tract embodying their views was published at that time by Robert Brown, who is to be regarded as their founder. The Independents are opposed both to the Presbyterian and Episcopal form of church government. The essential element of their doctrine is, that any community of Christians has a right to the regulation of its own ecclesiastical discipline and form of worship, independent of any other community; each congregation forming in itself a church. It is on their interpretation of this word ‘church’ (Gr. ekklesia), as used in Scripture, that they rest this doctrine, which they hold in common with the Baptists. They hold that when the same thing occurs in the Bible, it is used to denote either a single congregation, or the place where the congregation has met. It is never used, they hold, to denote the aggregate of Christian communities, the plural ‘churches’ being employed for this purpose; as, ‘Let your judgment keep silence in the churches’ (1 Cor. xiv. 34). Before admission to a congregation, they hold that there must not only be an intellectual assent to the historical narrative of Christianity, but that there must be satisfactory signs of the presence of its spiritual essence in the heart. Any man whom a congregation may think qualified to edify them, is eligible for the ministry. Ordination is performed by the ministers of neighbouring churches. It is considered merely an affair of oral declaration, and the man held in esteem by the church, conferred, gifts bestowed, or authority conveyed. The power of churches they hold to be purely spiritual, and acknowledge no head but Christ. It might at first sight appear likely that this perfect independence of each congregation would render their working harmoniously together a matter of great difficulty; but experience has shown the contrary. By leaving each congregation to act independently in its church discipline, many disputes which might have spread widely have ended where they began.

They are satisfied to agree about the essentials of religion, to sink minor differences which the fallibility of human judgment renders inevitable, to leave the determination of the accessories of its worship to the taste and feeling of each congregation, and to act in union for the furtherance of the great truths of Christianity. At the Westminster Assembly, called together by the authority of the parliament on 1st January, 1643, to determine the form and discipline of the national church, it was found that of the 70 or 80 members who composed it, only five were Independents. Presbyterianism was carried by a large majority. Through the influence of Cromwell, however, it never became really established; and in 1658, a great meeting was held, at which a declaration was drawn up, precisely the same as that of the Westminster Assembly, except that the chapter, in favour of the Presbyterian form of church government, was omitted, and another in favour of the Independent doctrine put in its place. It is difficult to say what might have been the result of this struggle between the Presbyterian and the Independent parties, had it not been put an end to by the restoration of Charles II. in 1660, and the re-establishment of Episcopacy.

By the passing of the act of Uniformity in 1662, the Independents, along with other Nonconformists, were subjected to much suffering. They are considered an express acknowledgment of the principles of Episcopacy. Its effect was to cause 1900 or 2000 of the clergy to leave the church. These are ‘the illustrious number’ of whom the Nonconformists speak. Still, the Independents increased; and the Revolution of 1688, and passing of the Toleration Act in 1698, at length brought them relief. Efforts were made about this time to bring about an accommodation between them and the Presbyterians, and in 1691, heads of agreement were drawn up. Finally, in 1730, Presbyterians, Baptists, and Independents formed themselves into a united body under the name of the Three Denominations. They were for long in the habit of consulting together for the general welfare; but this union has of late been disturbed by the withdrawal of the Presbyterians. An extraordinary manifestation of religious zeal, following what has been called the period of religious revivals in the latter part of last century. This was mainly owing to the influence of the Wesleys and Whitefield. Many of the enthusiasts joined the old Independents. By this accession, the Independents came to form the leading dissenting body in England except the Wesleyan Methodists; and this they still continue to be. By the census of 1851, the number of their churches in England and Wales is given at 3244, with accommodation places 76,756, besides 764 parish places, and an actual attendance of 793,142 (see Art. GREAT BRITAIN).
Indeterminate Problems—Index.

Independency has unquestionably prospered in England. Owen, Howe, Baxter, Calamy, Watts, Henry, Doddridge, Pye Smith, and many other illustrious names adorn its history.

There are ten training colleges for students in conflict with the Independent body in England. These are:

In Scotland, Independency may be traced back to the days of the Commonwealth, during which it was imported by the soldiers of Cromwell. It was not, however, until 1729 that it made much progress in Scotland. In that year, Robert Glass published a work avowing his conformity with the views of the English Independents, more particularly as these were expounded in the writings of the late Mr. Ballantyne.

Various sects arose about the same time, professing the leading doctrines of the Independents. Sandeman founded the Sandemanians; Dale, the old Scots Independents. It is not, however, till the close of last century that Independency can fairly be said to have established itself in Scotland. At this time, religious revivals took place under the agencies of James Haldane and John Aikman. The result was the formation of an independent church. In 1797, Haldane and Aikman made a tour as far north as the Orkney Islands, for the purpose of preaching. Others soon followed this example, so that itinerant preachers were at this time in almost every part of the country, both in England and Scotland.

The Relief Synod passed a resolution forbidding their clergy to allow any men to preach in their pulpits who were not regularly bred to the ministry of the gospel. Notwithstanding this expression, the itinerant preachers, animated by zeal for the cause of truth and the salvation of souls, were not deterred from their avowed purpose. In 1807, the Synod of Scotland, at the instance of Ballantyne, voted an annuity to Sandeman, 'Elder's Office,' was the cause of a great deal of unfortunate discussion among the Independents. 'Bitter contentions,' says Kinniburgh (Historical Survey of Congregationalism in Scotland), 'strife of words, jealousies, and divisions followed, of which none but such as passed through the stormy scene of those days can have an adequate idea.' The formation, in 1811, of the Glasgow Theological Academy (now removed to Edinburgh), has done much to restore to the Independent body the vigour which it had lost during this unfortunate controversy. The Congregational Union, to assist churches in supporting pastors, has also been of great benefit. The number of churches in Scotland, according to the return of 1851, is 192, with accommodation for 76,342 persons. The Morisonian doctrines (see MORISONIANS) have been openly professed by several of the Independent churches in Scotland. Baptists hold views similar to the Independents as to the Scripture meaning of the word 'church.'

In America, the first Independent church was founded by John Robinson at Plymouth, New England, in 1620. In 1637, the preaching of Antinomian doctrine caused much discussion in the church. By a synod convened in New England, Antinomianism was unanimously condemned. In 1638, Harvard College was founded. In 1658, the Savoy Confession was adopted. It still remains in force. About 1750, Unitarian principles spread widely in the congregational churches of America. In 1785, a separation took place between the Unitarians and the Trinitarians, but both still retain the congregational form of church government. The result is Unitarian 'Congregationalism,' according to Dr. Schaff, 'is the true... sect of the six northeastern states, and has exerted, and still exerts, a beneficial influence upon the religious and political life of the whole nation.' According to the Year-Book (1859) of the American Congregational Union, the number of Independent churches in the United States is nearly 2700, and the number of members about 250,000. Exclusive of Harvard and other colleges, in the administration of which they have a share, the American Independents possess theological seminaries at Andover, Bangor, New Haven, East Windsor, Oberlin, and Chicago. The following are good works to consult: Dr. Vaughan's 'History of English Nonconformity' (London, 1862); J. Fletcher's 'History of Independency' (London, 1862); Waddington's 'Early History,' and Mosheim's General Church History.

Indeterminate Problems. It was shown in the article upon the numbers of the unknown quantities could only be determined when the number of equations was equal to the number of unknown quantities, but that, if the latter exceeded the former, several values might be found for each unknown, in which case the problems which give rise to the equations are called indeterminate problems. For example, 'To find the number which, when divided by 2 and 3, leaves remainders 1 and 2,' is an indeterminate problem, admitting of an infinite number of solutions; for although only one unknown quantity appears in the question, yet, in order to form an equation, we are obliged to proceed in the following manner: as $x$ is divisible by 2, with a remainder 1, $x = 2p + 1$; again, as $x$ is divisible by 3, with a remainder 2, $x = 3q + 2$; hence we have the equation $2p + 1 = 3q + 2$ (one equation to find two unknown quantities), from which, by a process which is explained in the ordinary books on algebra, we find $x = 6r - 1$, where $r$ is any positive number whatever. The values of $x$ are, therefore, 5, 11, 17, 23, &c. In general, if the equation is of the form $ax + by = c$, the number of pairs of values of ($x$ and $y$) is finite; but if of the form $ax + by = c$, there are an infinite number of solutions. The Diophantine (q.v.) analysis exhibits a very interesting class of indeterminate problems of the second degree.

Index (more fully Index Librorum Prohibitorum), a catalogue published by Papal authority in the Roman Catholic Church of books the reading of which is prohibited to members of that church, whether on doctrinal, moral, or religious grounds. As a natural consequence of the claim of the Catholic Church to authority in matters of religion, and to infallibility, that church also claims the right of watching over the faith of its members, and of guarding it against every danger of corruption, the chief among which is held to be the circulation of books believed to be injurious to faith or to morality. The earliest recorded exercise of this restrictive authority is the prohibition of the writings of Arius; and a council of Carthage, in the year 398, issued, even for bishops, a similar prohibition of Gentile books, although it was not without the reluctance of the works of heretics. The earliest example of a prohibitory catalogue is found in the decree of a council held at Rome (494) under Pope Gelatus (Ludov. Conc. ii. col. 939—941), which, having
INDEX—INDIA.

The Roman Index are of two classes, either absolute and total, or partial and provisional, 'until the book shall have been corrected.' The edition of Quiroga, mentioned above, regards the latter. The ground of the prohibition may be either the authorship of the work, or its subject, or both. Under the first head are prohibited all the writings of heretics—i.e., the first founders of heresies—no matter what may be the subject. Under the second head are prohibited all books confessedly immoral, and all books on magic, necromancy, &c. Under the third are prohibited all books of heretical authorship treating on doctrinal subjects; all versions of the Bible by heretical authors; and all books, no matter by whom written, which contain statements, doctrines, or insinuations prejudicial to the Catholic religion.

The preparation of the Index, in the first instance, was committed to the care of the Congregation of the Inquisition in Rome; but a special Congregation of the Index was established by Pius V., and more fully organised by Sixtus V. This Congregation consists of a prefect (who is always a cardinal), of cardinals, of consultants, and of examiners of books (quaeritores). Its proceedings are governed by rules which have been authoritatively laid down by several popes, especially by Benedict XIV., in a constitution issued July 10, 1758, to which the reader is referred for the best and most authentic editions of the Index. The Roman Index is essentially a historical index, and as such misconceptions exist on the part of Catholics as well as of Protestants.

The growth of modern literature has, of course, entirely outstripped the limited and tardy machinery of this tribunal. A very small proportion even of the most anti-Catholic publications outside of Italy find their way by name to the Roman Index; but besides the positive prohibitions of the Index itself, there are certain general rules regarding the use of heretical books, the importation of which is considered perilous or pernicious reading is much limited among members of the Roman Catholic Church. These, however, would be entirely beyond the scope of our publication; nor could the rules for the Index itself be practically brought into operation in those countries where the Catholic and Protestant literatures are so interwoven, that it is impossible to separate them even in the ordinary intercourse of life. See Wetzer's Kirchen-Lexikon, art. 'Index.'

Few parts of the Roman Catholic system are more repugnant to intelligent Protestants than the institution of the 'Index,' as it strikes at the root of the fundamental principle of Protestantism itself—namely, that of private judgment. And this theoretical repugnance is increased by seeing that, in its practical working, such names as Gibbon, Robertson, Guicciardini, Sismondi, Hallam, Goldsmith (History of England), Pestis, Locke, East (Essay on Pure Reason), J. S. Mill (Political Economy), Whately (Logic), Bacon, Milton, Addams, Dante (De Monarchia), &c., are put under the ban.

INDIA.* An extensive region of Southern Asia, celebrated during many ages for its riches and various natural productions, its beautiful manufactures and costly merchandise, the magnificence of its sovereigns, and the early civilization of its people. It possesses capital interest to the Englishman, who, as the author of the Index, was practically brought into contact with that of his own country, as a hand where a company of British traders succeeded to the proud inheritance of the House of Timur, and a few forts and factories laid the foundation of an empire vaster than that of Aurungzebe—the most splendid appendage to the British crown.

Hither I. is the central peninsula of Southern Asia, and lies in 8° 4'—35° 30' N. lat., and 67°—92° E. long. According to those limits, its length may be stated approximately at 1900 miles. Its breadth, reckoned along the parallel of 25° N. lat., at 1600 miles, with an area of about 1,300,000 square miles. The natural boundaries of this vast region are, on the N., the range of the Himalaya Mountains; on the E., the line of the Indus divides it from Tibet; on the W., the Sulman Mountains divide it from Afghanistan and Beloochistan; from the mouth of the Indus to Cape Comorin, it is washed by the Arabian Sea, and thence to the mouths of the Ganges, by the waters of the Bay of Bengal; from this point, the Brahmaputra forms its eastern boundary. From the mouths of the Brahmaputra and the Indus, the east and west coasts, inclining towards the same point, meet at Cape Comorin, and thus give to Southern I. the form of an irregular triangle. The two sides of the triangle have each a coast-line of about 2000 miles. I. is, in fact, from its great extent of seaboard, essentially a maritime country.

Physical Features.—I. is, thus enclosed, presents a most diversified surface and varied scenery; it has 

* The name is borrowed by the Greeks from the Persians, who, however, applied the name of Hindus at first only to the dwellers on the banks of the river Sindhu (Sindhu). From the Persian name, the change of s into h, the Persian Hind is derived. Hindustan (the country of the Hindus) is a modern word applied by the Persians to the whole of India; but Europeans understand it as applied properly to that portion of it which lies north of the Vindhyas.
India.

Indeed been called 'an epitome of the whole earth.' Within its limits are to be found lofty mountain-ranges, towering far above the line of perpetual snow; broad and fertile plains, bathed in intensest sunshine; arid wastes, impenetrable forests, undulating hilly countries, and elevated plateaux. The surface is occupied chiefly by two great river-basins, those of the Ganges and the Indus, and a central table-land. To describe it more particularly, it may be said that India presents a variety of natural features—some of the highest mountains, the plain of the Ganges, the plain of the Indus, the mountainous region of Hindustan Proper, and the peninsular province of the country south of the Vindhyas.

The Plains of the Ganges, which includes Bengal, Bahar, the Doab, Oude, and Rohilkund, is a vast alluvial flat, extending from the Bay of Bengal to the Punjab. Throughout its entire length, the Ganges and its numerous tributaries spread out like the veins of a leaf, carrying everywhere their fertilising influence. The population of these fertile and well-cultivated plains is very dense. Scattered over the agricultural districts, and massed in the great cities and towns, there are not less than 80,000,000 people.

The Plains of the Indus, in the north-west, are less extensive than those of the Ganges, and are separated from the latter by the Aravulli Hills. The Punjab occupies the northern portion, South of the Punjab, and parallel with the river, the great sandy desert of the Indus extends for nearly 500 miles. The valley of the Indus is continued through the province of Sutiman to the ocean.—It has been estimated that the alluvial soils of I occupy a third of its entire surface. They are of inexhaustible fertility, and rich in vegetable matter.

The Highland Region of Northern Hindustan—the Copta M. I. of some geographers—extends from the Vindhyas Mountains as a base, to Rewari on the Jumna. It includes the table-lands of Malwa and Rajastan, and forms a vast plateau 700 miles long, by 100 to 250 miles broad, with an elevation of about 2000 feet above the level of the sea.

The Peninsular Region of India, south of the Vindhyas Mountains, which remains to be considered, is called by the natives the Deccan (q. v.). The most remarkable of its geographical features is the Southern Table-land—a vast plateau—extending from 12° to 21° N. lat., rising from 2000 to 3000 feet above the sea, and enclosed on all sides by lofty mountains, between which and the sea, on the east and west sides, a narrow strip of the fertile plain of the country is divided into several districts. From the low country on the coast to the central table-land, the mountains rise abruptly, in a succession of gigantic terraces or steps, and hence the name of 'Ghauts' (q. v.). The rivers of the Deccan rise in the Western Ghauts, and after traversing the table-land, descend to the sea over the Eastern Ghauts. The slope of the country corresponds with the course of the rivers; it has a gradual inclination towards the east. Of all the mountains of India, the Himalaya (q. v.) are the most famous. The Sullman Mountains, which form the western boundary of the trans-Indus provinces, extend from about 34° N. lat. 350 miles due south, and culminate in the lofty summit of Takh-ti-Sulaiman, or Solomon's Throne, 11,000 feet above the level of the sea, in 31° 33' N. lat. In breadth, this range varies from 5 to 14 miles in the highest portion. The Vindhyas range is the next important natural boundary, crossing India between the 22° and 25° of N. lat., thus separating Hindustan Proper from the southern or peninsula portion of the country, and forming the northern boundary of the valley of the Nerbudda. These mountains, which nowhere exceed 6000 feet in height, connect the northern extremities of the Western and Eastern Ghauts. The Sautpura range, between the Nerbudda and Taptap valleys, is a spur of the Vindhyas. The Western Ghauts run parallel with the Indian Ocean at a distance of 20 to 40 miles. On the opposite coast, forming the southern-eastern buttress of the table-land of the Deccan, are the Eastern Ghauts (see GAUTS). The physical geography of Southern India presents to the imagination a labyrinth of lofty masses upheaved amidst the vast plains that occupy the greater portion of the peninsula. Of these, the most remarkable are the Neelgherries (q. v.) or Blue Mountains, a minor mountain-ranges of I., the principal are the Nerval plateau, rising to an altitude of from 3000 to 6000 feet; the Sewalik range, near Hardwar, rising 3000 feet; the Kaia or Salt range, adjacent to the Sutiman range, rising 2500 feet; the Aravulli, between the basins of the Ganges and the Indus, culminating in Mount Abu at an altitude of 5000 feet; the Kattywar Hills, rising from 1000 to 3000 feet in the centre of the Kattywar peninsula; the hills of Bundelkund, 2000 feet; and the Rajmahal hills, rising from 5000 to 7000 feet.

The river system of I. is on a grand scale. The Indus (q. v.) traverses the north-west, and drains about 400,000 square miles of country. The Ganges (q. v.) traverses the plains of the north-east, and, along with its tributaries, drains an area of about 500,000 square miles. The eastern side of I.—the region southward of the Nerbudda, and eastward of the Malabar Ghauts—is watered by eighteen rivers, the principal being the Godavari, 800 miles long; the Kistna, 800; Cauvery (Kaveri), 470; Mahanadi, 520; Brahmin, 400; North Pennar, 350; and the South Pennar, 240. About twenty rivers water the western side of India. The most noteworthy are the Nerbudda, 800 miles long; the Tapt, 400—both of which flow into the Gulf of Cambay; the Myhi, 350; Luni, 320; Bunnas, 180; and the Bhadro, 130. The total number of rivers in I. that discharge themselves into the ocean is above 200.

Geology.—From observations that have been made at different points in I., the general features of its geological structure are to some extent known, but the details are not as yet clearly defined. The strata of the central plains and the adjacent districts with the known European series, have yet to be wrought out. Six years ago, a staff of geological surveyors were appointed, under the directorship of Professor Oldham, and important results have already been obtained. Many of the country's most noted strata of the northern plains have been surveyed and mapped, and the results have been published in three volumes of illustrative memoirs and maps. I. is bounded on the north-east by the range of the Himalaya, the great water-shed of Central Asia. These mountains consist of granitic rocks which have penetrated the stratified rocks, thrown them up in endless confusion, and metamorphosed them in many places into gneiss, mica-schist, clay-slate, or crystalline limestone. The nummulitic limestone of Middle Eocene age—a limestone crowded with nummulites, and often almost made up of them—occurs in several localities in the Himalaya, just as we find it in the Alps; and indeed it may be found at intervals throughout the countries which intervene between these two chains of mountains, often presenting itself in masses that are thousands of feet in thickness. The rise throughout the Himalaya is generally north-west, and is accompanied by the strike, with many local variations. Layers of sandstone and conglomerate extend along the base of the mountains. They are of Miocene age, containing the remains of species of camel, giraffe, hippopotamus, sivatherium, elephant, crocodile, and tortoise.
INDIA.

These are extensively developed in the Sewalk Hill the fossils of which have been elaborately described by Falconer.

A few of Post-tectonic alluvial deposits cover the whole of the river-basins of the Ganges and Indus, stretching across the north of I. from sea to sea.

The Eastern and Western Ghauts consist of metamorphic rocks, which are continued across the country to the north of the Godavery. Between this transverse belt of altered strata and the diluvial deposits of the north, a large tract of country is occupied by Palaeozoic rocks, frequently broken through and covered with different kinds of trap, and in some places overlaid with Secondary and fresh-water Tertiary strata. Several important memoirs on the structure of the district around Nagpur have been published by the Rev. Messrs. Haplo and Hunter. The principal coal-fields of I. occur in this Palaeozoic district. It is doubtful whether the coal-bearing strata belong to the Carboniferous period or not. The most important Indian coal-field is the Raniganj or Burdwan, on the river Damuda, which flows into the Hooghly 50 miles north of Calcutta. It is a belt of coal-bearing strata, consisting of coal and iron beds, as well as limestone, sandstone, and the hard sandstones, fitted for building purposes. The strata lie in a basin of metamorphic rocks, and cover an area of 600 square miles, at a distance of from 120 to 180 miles north-west of Calcutta. The iron ones consist of a black band, yielding 39 per cent. of coal; and magnetic ironstones, yielding from 60 to 70 per cent. From this field 365,000 tons of coal were raised in 1861. In the other coal-fields, occurring in different localities, only 64,12 tons of all kinds were raised in the same year. The Nerhbuila district, previous to 1861, had sent no coal to the market, but in that year, operations were begun in the coal-fields there with good prospects of success. The Punjab has hitherto supplied only a few tons of lignite yearly from the salt range, but no true coal; nor has any been raised in Oude, Madras, or Bombay. Much may be expected from the geological survey in developing the hidden treasures of the country.

The triangular region enclosed by the Eastern and Western Ghauts and the Godavery river is covered chiefly with Trappean rocks, with, however, scattered Palaeozoic and Tertiary strata. At Profonderry, they are Lower Cretaceous; and at Trichinopoly and Verdachomull, they belong to the Gault and Upper Greensand series.

The minerals of I. are very rich and varied; amongst them are included—besides coal, already mentioned—gold, silver, tin, copper, iron, plumber, lead; and precious stones—diamond, rubies, the beryl, topaz, and many others. Gold has been found in I. from time immemorial. The Deccan and the Malabar coast are believed to be gold-bearing districts, and at Dharwar, quartz reefs have been found of the richest description. Copper ore is abundant in Kurnoo. The iron region extends for many miles along the base of the Himalaya. The soil of I. is rich in nitre or Salt-petre (q. v.); sulphur has also been obtained.

Vegetable Productions.—The vegetation of I. is as varied as its soil and climate, and passes from the flora of a tropical to that of an alpine region. The groves of palm that border the coast, and, in the interior, the umbrageous mango topees, are striking features in the landscape. The coco-nut Palm (Cocos nucifera), the Palmaja Palm (Borassus flabelliformia), and the Betel Palm (Areca catechu), are amongst the most important of the palm tribe. Of the fig tribe, the most remarkable is the Banyan (Ficus Indica). The Bread-fruit Tree (Artocarpus incisa) grows on the Malabar coast. The Ficus regina, the Acca Arabica, and the Acca coccus are common. The mango, the pear, the peach, the apple, and others, are introduced into the warmest parts of I. Of course, the fruit most important in the Teak (Tectona grandis), which grows in the mountainous parts of Malabar, and the country bordering the Godavery. The Sal-wood (Santalum album), the Babul-wood (Chlorakylon cotinensis), the Sappan Tree (Oralum sappan)—are also highly prized. The Sil Tree grows along the Terai in a belt of forest from the Ganges to Hurtwar to Brahmaputra. Inhabitants of the forests of I. have timber trees growing on the northern slopes of the Himalayas, including the'Dodder, Garrandiana, Neoa (edible pine), several oaks, walnut, maple, hazel, horse-chestnut, and many others.

Of the fruits of India, the pine-apple, custard-apple, mango, pomegranate, melon, plantain, guava, pummeloose, loquat, jack, lime, are the most common.

Animals.—The domesticated animals are horses, asses, mules, oxen, buffaloes, sheep, and elephants. Of wild beasts, the most formidable is the Bengal tiger. The other beasts of prey are leopards, wolves, jackals, panthers, bears, hyenas, lynxes, tigers, and foxes; the tiger is the most dangerous of all. Of small animals, the mouse and antelope are common, as well as the bison and the muley. Monkeys abound in the forests, and the orang-outang is found on the Coromandel coast. Squirrels are very numerous. Of poisonous anakes, the cobra da capello, or black-hooded snake, the cobra manilla, and sand-snake are the most common.

The great Indian tortoise (Testudo Indica) has been known to measure 4 feet in length. The Ganges crocodile is the most noted of the saurians of Hindustan. Myriads of mosquitoes, butterflies, locusts, beetles, spiders, flying-bats, tarantulas, centipedes, the common fly and the fiery, wasps, bees, and ants of many kinds, are amongst the swarming insects of India. Fish abound in the rivers and seas: the most delicate is the mango-fish. A few of the characteristic birds of I. are peacocks, pheasants, jungle-fowl, pigeons, parrots, the ibis, the pagoda thrush, bulbul, tailor-bird, the flamingo, pelican, adjutant; and in the northern provinces, eagles, vultures, kites, falcons, rooks, ravens.

Climate.—The country extending over 25° of latitudinal zone extraordinary variation of weather exists in the torrid zone, and the other terminates in a range of lofty mountains rising far above the line of perpetual snow—a country embracing within its ample circumference lowland plains, elevated plateaux, and alpine regions, the climate must differ greatly. Hindustan Proper may be said to have three well-marked seasons—the cool, the hot, and the rainy. The cool months are November, December, January, and a part of February; the dry hot weather precedes, and the most hot weather follows the periodical rains. The climate of Southern I. is greatly regulated by the Memon (q. v.). The central table-land is cool, dry, and healthy. At Utsacand, on the Neighbours, 7300 feet above the level of the sea, the mean annual temperature is 57° F.; at Madras, 87°; Bombay, 84°; Calcutta, 79°; Bombay, 74°; and at Delhi, 72°. The fall of rain varies greatly in different parts of I. : at Calcutta, it measures annually from 50 to 80 inches; at Bombay, it averages 76; Madras, 66; Utsacand, 80; Nagpur, 53; Allahabad, 52; Varanasi, 46; Patni, 45; Cotagiri, 80; Darjiling, with 7000 feet of elevation, 122; in the Tenasserim provinces, 200 inches; while in North Assam, on the Cossy Hills, the fall is from 500 to 600 inches, or 50 feet. 142
Inhabitants.——The prevalent theory as to the ethnology of India is that, in very early times, it was inhabited by tribes or nations belonging to the same stock as the present inhabitants of Central Asia (the Mongolides of Latham); that at an epoch not yet determined, a branch of the Aryan race (q.v.) entered the peninsula from the north-west, established themselves first in the Punjab, and thence gradually diffused themselves as a dominant race over the whole of Northern and Central India, until the aboriginal population more or less, completely with their religious system and their language, and thus forming the Hindus. The tribes known as Bheels, Gonds, &c., still inhabiting the mountainous districts, are supposed to be outstanding islands of the aboriginal population that resisted the tide of Hindu conquest and civilization. The Hindus' influence extended feebly, if at all, into the Deccan, the great majority of whose inhabitants, therefore, are supposed not to belong ethnologically to the Aryan race. However this may be, it is a fact that the inhabitants of I., unlike those of China Proper, cannot now be considered a homogeneous people, since, through the manifold influence of climate and other causes, they differ as much amongst themselves as do the various nations of Europe.

In physique and cranial development, the Hindus are totally unlike the natives of the Indo-Chinese peninsula. Two ethnological influences are referable to two distinct types, have left their impress upon the people. In the higher castes, the features are regular, the head long, the skin is whiter than black, and the body admirably proportioned; the face is oval, and the eyes and hair black. In the northern provinces and more elevated parts, the men are strong and muscular. Women of the higher castes are often very handsome, with dark glossy hair, delicately formed limbs, feet and hands of exquisite mould, and a soft and polished skin.

To attain to anything like a fair estimate of Hindu character, it would be necessary to refer to the statements of many writers both ancient and modern. The mental condition and peculiarities of the ancient Hindu of the time of Alexander’s invasion and the Greek empire in I., have been described by the Greek writers of the time, of the Rig-Veda, an active life is portrayed; and we read of wars, triumphs, and defeats; but when the Aryan tribes had become settled on the rich plains of I., they appear to have concentrated their thoughts on the world within. They became passive, meditative, quiet, and full of faith; they devoted themselves to religion and philosophy. This is as true of the Hindu of to-day as it was 2000 years ago; but it is not so easy to arrive at a just estimate of his moral character. Ages of despotism, and a corrupt religion, have had a debasing effect on the Hindu mind; but whatever doubt there may be about the moral character of the Hindu, it is certain that, as a branch of the great Aryan family, he belongs to a highly gifted and intellectual race.

Two of the most striking peculiarities of the social condition of the Hindus are the institution of Caste (q.v.) and the Vignas. The latter is very simple. A village in Hindustan does not mean a collection of houses at a particular spot, but corresponds rather to what is called a township in America. It is a district embracing an area of some hundreds or thousands of square miles, and is under the administration of native functionaries, the principal of whom is the potali (head-inhabitant), a kind of chief magistrate, who superintends the affairs of the community, settles disputes, attends to the police and the collection of taxes. Among the other functionaries may be mentioned the curium, who keeps a register of the produce and the names of the proprietors, and draws up all deeds of sale, transfer, &c.; the Brahman, or village priest; and the schoolmaster. Besides these, every village has its astrologer, smith, carpenter, potter, barber, doctor, dancing-girl, musician, and poet, all of whom are rewarded for their labours out of the produce of the village lands. ‘Under this simple form of government the greater or less, the whole of the country have lived from time immemorial. The boundaries of the village have been but seldom altered; and though the villages themselves sometimes increased, and even desolated, by war, famine, and disease, the same name, the same limits, and even the same families, have continued for ages. The inhabitants give themselves no trouble about the breaking up and division of kingly lands; while the village remains entire, they care not to what power it is transferred, or to what sovereign it devolves; its internal economy remains unchanged; the potali is still the head-inhabitant, and still acts as the petty judge and magistrate. The whole relations of life were evolved into a system.

To the present inhabitants of I., including people who must now be viewed as so many distinct nations, no general statement can apply. The lothand and cringing Bengali resembles little the warlike Sikh of the Punjub, or the fierce Aryans of Rohuland; and the patient weaver of Dacca is wholly unlike the high-spirited Rajput of Central India. The Sikh is a born soldier, who despises the Hindoo, and hates the Mahomedan. He cares nothing for caste, and is brave, faithful, and independent. The Mohammedans of I. are degenerate followers of the Prophet, and their religion is a strange mixture of the doctrines of the Koran with the idolatry of Hindustan. The aboriginal tribes number about 20,000,000, and exist in the mountainous districts, in jungles, or the outskirts of towns, under the names of Bheels, Santals, Gonds or Khonds, Koles, Bengies, Domes, and Blaits. The two most important are the Bheels, who are found in Candeis, and the Khonds and Koles, who inhabit Orissa. The former were wont to live by plunder, and used to burn out of their jungles like tigers, and have been the most faithful of all the races. In 1825, after various methods of subduing them had been unsuccessfully tried by the British government, it was resolved to tempt them into military service. A Bheel corps was raised, into which all the wilder spirits were drafted, and the result has been a very decided improvement in the habits and disposition of the rest of the people. Roads have now been made through their country, and property is quite safe. The Khonds and Koles, however, are perhaps a more interesting race, since they have preserved more completely what may be regarded as the primitive religion of Hindustan. Forced into the jungles and mountains of Central I. by the victorious advance of the Aryan race from the north-west, they have preserved (in part at least), in their almost inaccessible retreats, the grim religion that prevailed in the peninsula before Brahmanism was heard of. That religion may be briefly characterized as idol worship. The Khonds sacrifice only to malignant deities, such as Siva the Destroyer, the goddess Kali, and the God of the Earth, whom they seek to propitiate by human sacrifices, principally of children, who, however, are not killed for this purpose but kidnapped from neighbouring tribes. Efforts have been made by the British government to suppress this horrid practice, but it still exists.

The Parsees, a mercantile and educated class,
INDIA

seated at Bombay, and along the west coast of I., are the descendants of the fugitive fire-worshippers of Persia (see PASAREES). It is estimated that the total population of I. approaches 200,000,000 people. It may be assumed,' says Mr. Montgomery, that out of the alleged 200,000,000, 20,000,000 are of the aboriginal class, slaves, pariahs, or devoid of caste; the Mohammedans may number from 10,000,000 to 15,000,000; the Parsees (or near the Satulje) about 2,000,000; the Jews, about 5,000,000; sundry others, hill-tribes, &c., perhaps 8,000,000; and the remaining 150,000,000, Hindus of the Brahmanical creed.

Religion.—Several of the forms of religion prevalent among the natives of I. are treated of apart (see BUDDHISM, MOHAMMEDANISM, PASAREES); what we have to consider here is that variety of creeds which is derived from Brahmanic sources, and known as the Hindu religion, or Hinduism. The term Hinduism, however, must not be taken as restricted to those forms of the Brahmanic religion which are in existence now; we have to look upon it as comprising all the phases of this creed up to its earliest period.

We may divide Hinduism into three great periods, which, for brevity's sake, we will call the Vedic, Epic, and Puranic periods, as our knowledge of the first is derived from the sacred books called the Vedas, and the second and third from the epics called the Râmdâvanâ, and more especially from the great epics, the Mahâbhârata; while the chief source of our information relative to the last period is that class of mythological works known under the name of Purâna and Tanâtra. It is necessary here to guard the reader against attempting to connect dates with the earlier of those periods. It has not been uncommon for writers on this subject to assign thousands of years before the Christian era as the starting-point of Hindu antiquity; others, more cautious, marked the beginnings of certain divisions of Vedic works with 1200, 1000, 800, and 600 years B.C. The truth is, that while Hindu literature itself is almost without known dates, owing either to the peculiar organisation of the Hindu mind, or to the convulsions of Indian history, the present condition of Sanscrit philology does not afford the scholar the requisite resources for embarking with an equal chance of success in such chronochronical speculations. This question of Hindu chronology will be more particularly considered in the article VEDA. In the meantime, the utmost stretch of assumption which in the actual condition of Hinduism it is permitted us to make is, that the latest writings of the Vedic class are not more recent than the 2d c. before Christ. A like uncertainty hangs over the period at which the two great epic poems of I. were composed, although there is reason to surmise that the lower limits of that period did not reach beyond the beginning of the Christian era. The Purânic period, on the other hand, all scholars are agreed to regard as corresponding with part of our medieval history.

If the Rig-Veda—the oldest of the Vedas, and probably the oldest literary document in existence—incorporated with the beginning of Hindu civilisation, the popular creed of the Hindus, as depicted in the Vedas and in the hymns, would remain here only the original creed of this nation, but throw a strong light on the original creed of humanit itself. Unhappily, however, the imagination, indulging in fancy and hypothesis, was the chief support of the ancients in their attempts to work on an eye of which they could the chronological position of this Veda. The Hindus, as depicted in these hymns, are far removed from the starting-point of human society; nay, they made up for this want of history by the already civilised communities experienced in arts, defending their homes and property in organised warfare, acquainted even with many vices which only occur in an advanced condition of artificial life. See VEDA. Yet in examining the hymns of the greatest number of the Rig-Veda hymns, it cannot be denied that they are neither ideas engendered by an imagination artificially influenced, nor such as have made a compromise with philosophy. Roughly, the Greeks (see the Hymns of the Rig-Veda) may divide the class of hymns into two, each by the might of the elements. The powers which turn his awe into pious subjection and veneration are—Agni, the fire of the sun and lightning; Indra, the bright, cloudless firmament; the Maruts, or winds, the chief elements of heaven; the Purusas, the dawn (see USHA); and various kindred manifestations of the luminous bodies, and nature in general. He invokes them, not as representatives of a superior being, before whom the human soul professes its humility; not as superior beings themselves, which may reveal to his searching mind the mysteries of creation or eternity, but because he wants their assistance against enemies—because he wishes to obtain from them rain, food, cattle, health, and other worldly goods. He complains to them of his troubles, and reminds them of the wonderful deeds they performed of yore, to coax them, as it were, into acquiescence and friendly reception of his prayers. He seeks to engage their greatness, for the sake of inducing your prompt appearance, as the indication of the (approach of) the showerer of benefits; or: 'Offer your nutritious viands to the great hero (Indra), who is pleased by praise and the voice of Páliuka (the minstrel), the king of the sun, the two invincible deities who ride upon the radiant summit of the clouds as upon a well-trained steed. Indra and Višnâu, the devout worshipper glorifies the radiant approach of you two who are the granters of the wealth', and who destroy sinners and the mortal who worships you an immediately receivable (reward), through the distribution of that fire which is the scatterer (of desired blessings). Such is the strain in which the Hindu of that period addressed his gods. He seeks them, not for his spiritual, but for his material welfare. Ethical considerations are therefore foreign to these instinctive outbursts of the pious mind. Sin and evil, indeed, are often referred to, and the gods are praised and adored because of the praise they receive at the hands of the believer. He is the foe, the robber, the demon—in short, the borderer infesting the territory of the 'pious' man, who, in his turn, injures and kills, but, as adoring Agni, Indra, and their kin, is satisfied that he can commit no evil act. Yet we should be likewise wrong did we judge of those acts of retaliation by the standard of our own ethical laws. So far, indeed, from reflecting unfavourably on the internal condition of the Hindu community, the features of which may be gathered from these hymns, they seem, on the contrary, to bespeak the union and brotherhood which existed amongst its members; and the deities, united to general of hymns, are addressed to the gods for the suppression of internal dissensions or public vices, bears, apparently, testimony to the good moral condition of the people who wants are not a sin in the circle founds.

It may be imagined that the worship of elementary beings like those we have mentioned was originally a simple and harmless one. By far the greatest number of the Rig-Veda hymns know of no other offering. A man has to offer to these gods, it consists of the juice of the soma or moon-plant,
which, expressed and fermented, was an exhilarating and inebriating beverage, and for this reason, probably, was deemed to invigorate the gods, and to increase their beneficial potency. It was presented to them in ladles, or sprinkled on the sacred Rusa grass. Clarified butter, too, burnt in the fire, is mentioned in several hymns as an oblation agreeable to the gods; and it may have belonged to this, as we hold, primitive stage of the Vedic worship.

The great horse, the divine steed, is codified in the Rig-Veda which depart already materially from the simplicity of the conceptions we are referring to. In these, which we conceive to be of another order, this instinctive utterance of feeling makes room for the language of speculation; the allegories of poetry yield to the mysticism of the reflecting mind; and the mysteries of nature becoming more keenly felt, the circle of beings which overawe the popular mind becomes enlarged. Thus, the objects by which Indra, Agni, and the other deities are propitiated, become gods themselves; Soma, especially, the moon-plant and its juice, is invoked as the bestower of all worldly boons. The animal sacrifice—the first and most solemn of the elementary rituals—is given to the offerings of Soma, or of clarified butter—is added to the original rites. We will quote a few verses from the second book of the Rig-Veda, which may illustrate the essential difference between this order and the former. Although in all the Rig-Vedas the horse is the horse of the sacrifice which is invoked by the worshipper, and its properties are praised in the following strain

By great oaths, O Horse, to be glorified,
whether spurring from the firmament or from the water, inasmuch as thou hast neighed, for thou hast the wings of the falcon and the limbs of the deer. Trita harnessed the horse which was given by Yama, Indra first mounted him, and Gandharba seized his reins. Vasus, you fabricated the horse from the sun. Thou, horse, art Yama; thou art Adivya, thou art Aitra by a mysterious act: thou art associated with Soma. The sages have said there are three bindings of thee in heaven, &c.

Mystical language like this doubtless betrays the aberration of the religious instinct of a nation; but it also reveals the fact, that the pious mind of the Hindu was a longer satiated with the adoration of the elementary or physical powers; it shows that the religion endeavoured to penetrate into the mysteries of creation. This longing we find, then, expressed in other hymns, which mark the beginning of the great period of the Vedic speculation. The following few verses may tend to illustrate the nature of this third class of hymns, as they occur in the oldest Veda: 'I have beheld the Lord of Men,' one poet sings, 'with seven sons [i.e., the seven solar rays], of which delightful and benevolent (deity), who is the object of our invocation, there is an all-pervading middle brother, and a third brother [i.e., Vayu and Agni, the younger brothers of Adivya, the sun], well fed with (oblations of) clarified butter. They yoke the seven (horses) to the one-wheeled car [i.e., the orb of the sun, or time, or a year]; one horse [i.e., the sun], named seven, bears it along; the three-axled wheel [i.e., the day with its three divisions, or the year with three seasons—hot, wet, and cold; or time—past, present, and future] is undecaying, never loosened, and in it all these regions of the universe abide. . . . Who has seen the primal (Being) at the time of her being born? What is that endowed with substance which the unsubstantial sustains? From earth are the breath and blood, but where is the soul? Who may repair to the soul to ask this? Immature (in understanding), undeciphering in mind, I inquire of those things, which are hidden, (even) from the gods, (that are) the seven threads which the sages have spread to envelop the sun in whom all abide!' Another poet sings: 'Ther e was no entity or non-entity; no world, or sky, or aught above it; nothing anywhere in the history of are, one, involving, or involved; nor water deep or dangerous. Death was not, nor was there immortality, nor distinction of day or night. But That breathed without exhalation, single, without thoughts, without body, without birth. Other than him, nothing existed (which) since (has) been. . . . Who knows exactly, and who shall in this world declare, whence and why this creation took place? The gods are subsequent to the production of this world, then who can know whence it proceeded, or whence this varied world arose, or whether it uphold itself or not? He who in the highest heaven is the ruler of this universe, does indeed know; but not another one can possess this knowledge.'

As soon as the problem implied by passages like these was raised in the minds of the Hindus, Hinduism must have ceased to be the pure worship of the sun, moon, and fire. Henceforward, then, we see it either struggling to reconcile the latter with the idea of one supreme being, or to emancipate the inquiry into the principle of creation from the elementary religion recorded in the oldest Veda. The Vedic order is principally shewn in that portion of the Vedas called Brāhmaṇa (see VEDA), the second in the writings termed Upanishad (see UPAÑISHAD). In the Brāhmaṇa—a sort of the neater, and not to be confounded with the similar word becomes masculine gender, denoting the first Hindu caste—the mystical allegories which now and then appear in what we have called the second class of Vedic hymns, are not only developed to a considerable extent, but gradually brought into a systematic form. Epithets given by the Rig-Veda poets to the elementary gods are spun out into legends, assuming the shape of historical narratives. The simple and primitive worship mentioned in the hymns becomes highly complex and artificial. A ponderous ritual, founded on those legends, and supported by a far more advanced condition of society, is brought into a regular system which requires a special class of priests to be kept for its performance. Some of the Vedic hymns seem to belong already to the beginning of this period of the Brāhmaṇa worship, for in the second book of the Rig-Veda several such verses are enumerated in reference to the adoration of Agni, the god of fire; but the full contingent of sixteen priests, such as is required for the celebration of a great sacrifice, does not make its appearance before the composition of the Brāhmaṇas and later Vedas. Yet, however wild many of these legends are, however distant they become from the instinctive veneration of the elementary powers of nature, and however much this ritual betrays the gradual development of the institution of castes—unknown to the hymns of the Rig-Veda—the ancient tradition of the Brāhmaṇas teaches, their ethical qualities are put forward for imitation and praise. Truth and untruth, right and wrong—in the moral sense which these words imply—are not seldom emphasized in the repetition of the same thoughts and songs; and several rites themselves are described as symbolic representations of these and similar qualities of the good and evil beings, worshipped or abhorred. A second feature is the tendency, in these Brāhmaṇas,
determining the rank of the gods, and as a consequence, of giving prominence to one special god amongst the rest; whereas in the old Vedic poetry, though we may discover a predilection of the poets to bestow more praise, for instance, on Indra and Agni, than on other gods, yet we find no intention, on their part, to raise any of them to a supreme rank. Thus, in some Brhadmanas, Indra, the god of the firmament, is endowed with the dignity of a ruler; in others, Vishnu receives the expression of the attributes of superiority. This is no real solution of the momentous problem hinted at in such Vedic hymns as we quoted before, but it is a semblance of it. There the poet asks 'whence this varied world arose'—here the priest answers that 'one god is more elevated than the rest;' and he is satisfied with regulating the detail of the Soma and animal sacrifice, according to the rank which he assigns to his deities.

A real answer to this great question is attempted, however, by the theologians who explained the 'mysterious doctrine,' held in the utmost reverence by all Hindus, and laid down in the writings known under the name of Upanishads, which must suffice here to state that the object of these important works is to explain, not only the process of creation, but the nature of a supreme being, and its relation to the human soul. In the Upanishads, Agni, Indra, Vahnu, and the other deities of the Vedic hymns, become symbols to assist the mind in its attempt to understand the true nature of one absolute being, and the manner in which it manifests itself in its world. The human soul itself is of the same nature as this supreme or great soul: its ultimate destination is that of becoming re-united with the supreme soul, and the means of attaining that end is not the performance of sacrificial rites, but the comprehension of its own self and of the great soul. The doctrine which at a later period became the foundation of the creed of the educated—the doctrine that the supreme soul, or (the neeter) Brahman, is the only reality, and that the world has a claim to notice only in so far as it emanated from this being, is already clearly laid down in these Upanishads, though the language in which it is expressed still adapts itself to the legendary and allegorical style, which characterises the Brhadmanas period. The Upanishads became thus the basis of the enlightened faith of India. They are not a system of philosophy, but they contain all the germs whence the three great systems of Hindu philosophy arose, and like the latter, while revealing the struggle of the Hindu mind to reach the comprehension of one supreme being, they advance sufficiently far to express their belief in such a being, but at the same time acknowledge the inability of the human mind to comprehend its essence. For the different periods which must be distinguished in the composition of these works, and for the gradual development of the general ideas briefly adverted to here, we refer the reader to the article UPANISHAD.

The Epic period of Hinduism is marked by a similar development of the same two creeds, the general features of which we have now traced in the Vedic writings. The popular creed strives to find a centre round which to group its imaginary gods, whereas the philosophical creed finds its expression in the groundwork of the Sankhya, Nyaya, and Vedanta systems of philosophy. In the former we find two gods in rising to the highest rank, Vishnu and Siva; for as to Brahman (the masculine form of Brahman), though he was looked upon, now and then, as superior to both, he gradually disappears, and becomes merged into the philosophical Brahman (the neuter form of the same word), which is a further evolution of the great soul of the Upanishads. In the Bhagavadgita, the superiority of Vishnu is admitted without dispute; in the great epics, the Mahabharata, however, which unlike the former epics, is the product of successive ages, there is an apparent rivalry between the claims of Vishnu and Siva to occupy the highest rank in the pantheon; but Sanscrit philology will first have to unravel the chronology of these writers, before it can unravel the work, to lay bare its groundwork, and to show the gradual additions it received, before it will be able to determine the successive formation of the legends which are the basis of classical Hindu mythology. Yet so much seems to be clear even already, that there is a predilection during this Epic period for the supremacy of Vishnu; and that the policy of incorporating rather than combating antagonistic creeds, led more to a distant admission than to a warm support of Siva's claims to the highest rank. For the character of these gods, for the relation in which the conception of these beings stands to that of the Vedic time, for the new mythology, and for the group of mythological beings connected with both of them, we refer the reader to the respective articles. We will point, however, to one remarkable myth, as it will illustrate the altered character of the deities. We have seen that Vishnu is, in the Vedic hymns, the immortality of the gods is never matter of doubt; most of the elementary beings are invoked and described as everlasting, as liable neither to decay nor destruction. But the hymns receive may add to their comfort and strength: they may invigorate them, but it is nowhere stated that they are indispensable for their existence. It is, on the contrary, the pious sacrificer himself who, through his offerings, secures to himself long life, and, as it is sometimes hyperbolically called, immortality. And the same notion prevails throughout the oldest Brhadmanas. It is only in the latest work of this class, the Sattapatha Brhadmanas, and more especially in the Epic poems, that the gods are made to be mortal in the beginning, and as becoming immortal through exterior agency. In the Sattapatha Brhadmanas, the juice of the Soma plant, offered by the worshipper, or at another time clarified at the Epit altar, or even external sacred sacrifices impart them the immortality. At the Epic period, Vishnu teaches them how to obtain the Amritas or beverage of immortality, without which they would go to destruction; and this religious beverage is now the object of increased by imagination, of the various substances which in the Vedic writings are called or likened to Amrita, i.e., a 'substance that frees from death.' It is obvious, therefore, that gods like these could not strike root in the religious mind of the nation. We must look upon them more as the gods of poetry than of real life; nor do we find that they enjoyed any of the worship which was allotted to the two principal gods, Vishnu and Siva.

The philosophical creed of this period adds little to the fundamental notions contained in the Upanishads; but it frees itself from the legendary dress which still imparts to those works a deep tinge of mysticism. On the other hand, it concurs and develops the notion, that the union of the individual soul with the supreme spirit may be added by penances, such as peculiar modes of breathing particular postures, prostrated fasting, and the like; in every particular who are engaged in the Yoga doctrine. The most remarkable Epic work which inculcates this doctrine is the cele brated poem Bhagavadgita, which has been wrongly considered by European writers as a pure Sankhya work, whereas Sankara, the great Hindu theologian,
who commented on it, and other native commentators after him, have proved that it is founded on the Yoga belief. The doctrine of the reunion of the individual soul with the supreme soul, was necessarily founded on the assumption, that the former must be absolutely pure before it can be remerged into the source whence it proceeded; and since one human life is apparently too short for enabling the soul to attain its accomplishment, the Hindu mind concluded that the human soul must be born again, in order to complete the work it had left undone in its previous existence, and that it must submit to the same fate until its task is fulfilled. This is the doctrine of metempsychosis, which is the absence of a moral process, and is a logical consequence of a system which holds the human soul to be of the same nature as that of an absolute God. The beginning of this doctrine may be discovered in some of the oldest Upanishads, but its fantastic development belongs to the Epic time, where it pervades the legends, and affects the social life of the nation. See Metempsychosis.

The Puranic period of Hinduism is the period of its fullest development, when female energies were corded. Its pantheon is nominally the same as that of the Epic period. Brahma, Vishnu, and Siva remain still at the head of its imaginary gods; but whereas the Epic time is generally characterised by a friendly harmony between the higher and lower orders of the divine spheres, the Puranic period shows discord and destruction of the original ideas whence the Epic gods arose. Brahma withdraws, in general, from the popular adoration, and leaves Vishnu and Siva to fight their battles in the minds of their worshippers for the highest rank. The elementary principle which originally inured in these deities is thus completely lost sight of by the followers of the Puranas. The legends of the Epic poems relating to these gods become amplifying and historical according to the sectarian tendencies of the masses; and the divine element which still distinguishes these gods in the Râmâyana and Mahâbhârata, is now more and more mixed up with worldly concerns and intersected with historical events, digested in their turn to suit individual interests. Of the ideas implied by the Vedic rites, scarcely a trace is visible in the Puranas and Tantras, which are the text-books of this creed. In short, the unbridled imagination which pervades these works is neither pleasing from a poetical, nor elevating from a philosophical point of view. Some Puranas, it is true—for instance, the Bhâgavata—make in some sense an exception to this aberration of original Hinduism; but they are a compromise between the popular and the Vedânta creed, which henceforward remains the creed of the educated and intelligent. They do not affect the worship of the masses as practised by the various sects; and thus worship itself, whether harmless, as with the worshippers of Vishnu, or offensive, as with the adorers of Siva and his wife Durgâ, is but an empty ceremonial, which, here and there, may remain the last symbolical worship of the Vedic Hindu, but, as a whole, has no connection whatever with the Vedic scriptures, on which it affects to rest. It is this creed which, with further deteriorations, caused by the mixture of many foreign beliefs, to rise the worship of the masses in India. The opinion these entertain, that it is contemnated by the ritual, as well as by the theological portion of the Vedas, is the redeeming feature in so far as, for popular literature, it is nothing less than to disabuse their mind on this score, by reviving the study of their ancient and sacred language, and by enabling them to read again their oldest and most sacred books, it may be hoped that a proper education of the people in this respect, by learned and enlightened natives, will remove many of the existing errors, which, if they continued, must inevitably lead to a further and, ultimately, total degeneration of the Hindu race.

The philosophical creed of this period, and the creed which is still preserved by the educated classes, is that derived from the tenets of the Vedânta philosophy. It is based on the belief of one supreme being, which imagination and speculation endeavoured to reconcile all the perfections conceivable by the human mind, but the true nature of which is, nevertheless, declared to be beyond the reach of thought, and which, on this ground, is defined as not possessing any of the qualities by which the human mind like the bedelgious or material entity. See VEDÂNTA.

Hindu Sects.—This designation applies to the sects which arose during the third period of Hinduism. They suppose that their worship is countenance over the Vedas; but its real origin is derived from the Purânas and Tantras. See these articles. There are three chief divisions of these sects—the adorers of Vishnu, of Siva, and of the wives or consorts of these gods, called SAIJAS, and SAKAS. Besides these great sects, there are some of limited extent and total insignificance, such as the worshippers of Agni, the god of fire; of Shiva, the sun-god; of Ganeśa, the god of wisdom, and his venerated, and the obviator of innumerable details; of the Worshippers of the Works of the late H. H. Wilson, containing a Sketch of the Religious Sects of the Hindus.

Languages.—A great many different tongues and dialects are spoken in this vast country. The languages spoken in the north of India, by the Hindus proper, are descended from the ancient Sanscrit (q. v.). The chief dialects are the Hindi, the principal literary language of the non-Mohammedian population; Hindustani, or Urdu, which is Hindi corrupted by a mixture of Arabic and Persian words; Bengal; Punjabi; Mahâratt; Gujarât; &c. The languages of the Deccan have only a slight infusion of Sanscrit roots, and are more akin to the Tartar languages of Central Asia. They are called the Dravidian group, and include Tamil, Telugu, Malayalam, and Canarese. The languages of the hill-tribes or aborigines have not hitherto been sufficiently examined, to warrant any conclusions with regard to their affinity.

Manufactures and Arts.—In manufactures, the Hindus attained to marvellous perfection at a very early period, and the courts of imperial Rome glittered with the gold and silver brocades of Delhi. The muslins of Dacca were famous ages ago throughout the civilised world. In the International Exhibition of 1862, splendid specimens of the gorgeous manufactures and patient industry of the Hindus were displayed. Textile fabrics of inimitable fineness; tapestry glittering with gems; rich embroideries and brocades; carpets wonderful for their exquisite harmony of colour; silver filigree-work, fine and delicate as lace; enamel of the most brilliant hue; inlaid wares that require high magnifying power to reveal their minuteness; cups and goblets of chaste design; furniture most elaborately carved and of curiously formed antler, temper, are amongst the objects that prove the perfection of the art-industry of India. All these are produced with the rudest tools, and without any machinery. The European manufacturer will never succeed in imitating the work, which, the Hindu, though excessively dexterous, is totally devoid of ingenuity. Arts and manufactures have consequently made no progress in I. for the last 1000 years. The system of caste has led to the
regular hereditary transmission of professions from
parent to son, as at present find them in practice.

In Agriculture, the Hindus evince considerable
skill, and though their system is in many respects
rude, it appears well suited to the country. They
have practiced it very remote times for even
during the Vedic period they cultivated fields,
and removed the produce in carts. The native farmers
alternate the pulses with the cereals, and Dr Royle
is of opinion that the system of rotation of crops
has been derived from India. The Hindu farmer
understands extremely well how to maintain
the producing power of his land.

&c., of I., see Sanscrit Literature, MIMASAKA,
NYASA, SHASTRA, VEDANTA.

History. See following article.

INDIA, BRITISH, includes not only almost the
whole of the country described in the preceding
article, but also several provinces on the eastern side
of the Bay of Bengal. It extends from the gloomy
passes and cyclopean gates that shut in Hindustan
on the north and north-east to Cape Comorin, about
1800 miles; and from Kurrachi in Sinde to Rangoon
in Pegu, about 1900 miles. Its area is fully 1,500,000
square miles, with a land boundary of about 4500
miles, and a coast-line of almost equal extent.

For administrative purposes, the different countries
and provinces of British India are grouped into
several local governments, under governors, lieu-
tenant-governors, and commissioners, all of whom
are subject to the supreme authority of the
province-general. There are at the present time
three presidencies—Bengal, Madras, and Bombay;
four lieutenant-governorships—the North-west Pro-
vinces, the Punjab, Oude, and British Burmah;
and besides these, Nagpur or Berar, together with
Saugor and the Nebuldah territories, form a central
province governed by a commissioner. The follow-
ing table, abridged from Montgomery Martin's
British India, shows the

Government, Civil and Military.—The act for
better government of India (21 and 22 Vict. c. 106)
received the royal assent August 2, 1858; and on
the 1st of November in the same year, a royal
proclamation signified to the people of I. that the
hundred years' reign—the mysterious 'raj'—of the
East India Company had terminated, and that the
Queen of England was henceforth to be Empress of
Hindustan, governing by her vice-regent the terro-
lities lately ruled by the great Company. The
anomalous double government of I. by a court of East
India Directors and a Board of Control, composed of
Queen's ministers, having ceased, it will be unnece-
sary to enter into details respecting its organisa-
tion. The following sketch of the government of
I., as at present constituted, its finance, moral and
martial progress, and present condition, is derived
chiefly from Montgomery Martin's Progress and
Present State of British India (1862).

The Home Government for I. is vested in a
secretary of state (salary, £2500) and a council of
fifteen members (salary of each, £1000). The
The Local and Executive Government is administered by a governor-general or viceroy, governors, lieutenant-governors, and governor-general, who holds an office the highest filled by an uncrowned head, is appointed by the crown for a term of about six years, with a salary of £4,000, and is required to render valid the government and establishment at Calcutta, and a country residence at Barrackpōr. He is assisted by a council of five ordinary members, who may be regarded as his ministers. Three of these are appointed by the secretary of state in council from the servants of the crown or company of ten years' standing, and the remaining two by her Majesty's warrant. The commander-in-chief may be constituted an extraordinary member of council by the consent of the crown. The council is a legislative council, consisting of four official, four non-official, and three native members; and similar councils will shortly be organised in the north-west provinces, the Punjab, and probably in Oud. A more generous policy towards the natives of India has hitherto been curtailed by the original jurisdiction, and its gradual extension, while securing their fidelity to the British crown, will offer to native talent an honorable employment in the administration of civil affairs, a vocation open to the Hindu aristocracy even under the rule of the Mogul.

The Administration of the Native States is generally vested in an hereditary and despotic prince, aided, if it may be, by a council of nobles, and controlled in some degree by a British resident. The British government has lately conceded to the native independent princes of India the right of adoption in regard to succession on failure of natural heirs. This act practically reverses the policy of annexation which has hitherto been the rule in India, and which has mainly contributed to the enormous increase of our territories of late years, especially under the administration of Lord Dalhousie.

The Covenanted Civil Service is composed of Europeans who conduct the general administration of British India. It includes about 800 members, with salaries ranging from £100 to £3000 per annum. The patronage of the Covenanted Civil and Military Services was until lately a monopoly of the East India Company, but the staff of the Covenanted Civil Service is now recruited from the successful candidates at competitive examinations, instituted for the purpose. The successful administration of India is of great and growing importance to Great Britain, for the loss of L, besides depriving the educated middle classes of Great Britain of a fine field for their energies and talents, would involve the loss of the debt of L, which amounts to £120,000,000, besides £50,000,000 invested in Indian railways, both sums derived chiefly from British capitalists. £200,000,000 more are embarked in banks and joint-stock mercantile establishments.

The Unconvened Civil Service, appointments to which are made by the authorities in India, is composed of Europeans, Eurasians (the class sprung from native mothers by European fathers), and natives, with salaries ranging from £12 to £3000 per annum. Candidates are not subjected to the examinations through which those who enter the Covenanted branch must pass. In the year 1861, the service included 6212 members, of whom 3964 were Europeans and Eurasians, and 2228 natives of India.

Military Force.—The Indian military service, like the civil service, has been undergoing a thorough re-organisation, consequent on the great mutiny, and the transfer of the government of the country from the East India Company to the Crown. In 1857, at the outbreak of the mutiny, the Indian Army (q. v.) consisted of about 27,700 men, of whom 35,000 were Europeans and 222,000 natives. During the mutiny, the native army of Bengal was almost entirely broken up. Fifteen regiments of regular native infantry, the local infantry, the Gurkha and irregular line regiments, eight regiments of irregular cavalry, and the sappers and miners, were all that remained at the close of 1860 of the old native army of Bengal.

The strength and cost of European troops in India is required to render valid the measures passed by the governors of Madras and Bombay in council, and they are further subject to the veto of the Crown. The lieutenant-governor of Bengal, who rules 40,000,000 of people, is also assisted by a legislative council, consisting of four official, four non-official, and three native members; and similar councils will shortly be organised in the north-west provinces, the Punjab, and probably in Oud. A more generous policy towards the natives of India has hitherto been curtailed by the original jurisdiction, and its gradual extension, while securing their fidelity to the British crown, will offer to native talent an honorable employment in the administration of civil affairs, a vocation open to the Hindu aristocracy even under the rule of the Mogul.

There are more than 3000 European officers attached to the army in India, and 800 commissioned medical officers. Great reductions have taken place in the regular native army, which now numbers about 120,000 men.

The Police, civil and military, forms an important force, and is to a great extent taking the place of the regular army. In Bengal, for instance, the military police includes ten battalions of infantry, each 700 strong; three squadrons of cavalry, and some local levies; in all, about 10,000 men, of various races, with forty European officers. The whole police force of India has lately been re-organised on one uniform system, with a central organisation of its own in each presidency.

Marine Department.—There is no longer a separate Indian navy, but a Pilot Service is still maintained.

Administration of Civil Justice.—This, like everything else in India, is in a state of transition. The supreme court at Calcutta, and the Sudder Mofussil, or county courts, were abolished in 1861, by an act of parliament, and high courts of judicature were established at Calcutta, Bombay, and Madras, and in the north-west provinces, under the control of a chief-justice, and as many other judges, not exceeding fifteen, as her Majesty may appoint. These high courts are to exercise civil, criminal, on the great, intestate, and matrimonial jurisdiction, original and appellate, by single judges or by division courts; and now, for the first time, the verdicts of the inferior courts will be submitted to men of high
of the revenue, to enjoy any proprietary rights was totally ignored; and under Sir Thomas Monro, the ryotwary system was introduced, by which government makes a separate settlement with each individual cultivator or ryot, who is recognised as the virtual proprietor of the land, or tenant direct under government, so long as he pays the land-tax annually charged on his estate or farm. A complete land survey by government officials is at present in progress, in order to settle, in conjunction with a revenue settlement, a future tenure under government, so that the ryotwary system may be introduced in a permanent basis. A most important recent measure sanctions the sale of free simple of waste lands in certain districts, as well as lands for building purposes.

Opium (q. v.) is produced in large quantities, sometimes amounting to 50,000 chests a year, but this is a constantly fluctuating source of revenue, is estimated at about £29,000,000, and has convenient and productive items of taxation. A property-tax of 3 per cent. (which is now under revision) was levied on 31st July, 1860, and a personal tax of 1 per cent. is charged on every one of the country's inhabitants in any capacity. For the year 1860—1861, the gross receipts of the revenues of India amounted to £42,903,234. The total expenditure of that year, including guaranteed interests on the capital of railway and other companies, amounted to £4,021,385. (See Finance and Revenue Accounts of the Government of India for the year 1860—1861.) As a result of recent reforms, and the financial measures of Mr. William Wood, the Financial Secretary, Mr. Laing, the present Governor-General, has been changed into a surplus, in the year 1862—1863, of £1,428,623, and the expenditure in 1860—1861 is reduced to £35,905,521. In 1860 the debt of India was £288,107,460—viz., in 1., £71,909,460; and in England, £26,138,000. The cost of the great mutiny, to the end of the financial year 1859—1860, including losses, destruction of public buildings, and probable amount of compensation to sufferers, is estimated at about £29,000,000.

Currency.—In British India, accounts are kept in rupees, annas, and pie—16 annas going to the rupee, and 12 pie to the anna. The coins are rupees (value 2s. sterling) and half and quarter rupees, in silver; and in copper, 12, 6, and 3 annas. During the ten years ending 1857—1858, the mints of Calcutta, Madras, and Bombay issued in gold, silver, and copper coins, nearly £350,000,000 sterling. The new coinage bears the impress of the Queen in the native costume. The State notes to the amount of four millions were issued by means of the Bank of England in March 1862.

Moral and Material Progress—Religion and Education.—In Queen Victoria's Proclamation to the Princes, Chiefs, and People of India, read in the principal cities of India, November 1, 1858, it was declared, 'that none shall be in anywise favoured, none molested or disquieted by reason of their religions faith and observances, but that all shall alike enjoy the equal and impartial protection of the law.' The fullest toleration in matters of faith is enjoyed throughout British India. Fanaticism only, as when it seeks to enforce the cruel satti, or offers human and animal sacrifices, is cursed by the British power. There is no exclusively endowed state-church, but government continues to pay the state grants made to Hindu temples and to Mohammedan mosques under the past regime, or compromise claims where it is possible by a grant of land or one money payment. Clergymen of the Church of England and of the Church of Scotland are retained on the government establishment as civil and military chaplains. In 1814, a bishop of Calcutta

* Including the North-west Provinces, the Punjab, and the territories under British control.
+ Taxes on sale of liquors, drugs, &c.
\$ Tax on houses and trades, levied chiefly in Madras.
The educational system adopted in India has a distinct central organisation in each presidency under a director of public instruction, assisted by inspectors of schools, one to each of the circles into which the presidency is divided. A university has been established at each presidency town; and besides the university, there are two grades of education in the secondary or middle class, and in the primary or popular classes of schools. In Bengal, 18,000 scholars attend the 300 colleges and schools, not endowed by government. The local annual sum expended on educational purposes is about £100,000. The educational department of Madras is maintained by government at an annual cost of about £5,000. In Bombay, there are 25 English schools, with 3,000 scholars, and 50 vernacular schools, with 28,000 scholars, spread over the presidency; besides colleges at Ahmedabad and Belgaum, and an engineering school at Poona. In 1853, 10,000 students were enrolled, or in course of instruction, in schools, with 225,000 boys, in operation, and there are colleges at Agra, Benares, and other cities. The natives manage and maintain 6,000 indigenous schools, with 65,000 boys.

Christian mission work in India was one of the earliest fields of Christian missions. Tradition assigns it as the scene of the apostle Thomas's labours and martyrdom. Whether this was the case or not, we find a Syrian church planted in Malabar in the 14th century, and native Christians were found in Ceylon as early as the 4th century. The Jesuit missionaries, from the middle of the 16th century onwards, had a large success in India. To disarm prejudice, they are said to have introduced themselves to the notice of the people, not as foreigners, but as white Brahmans, and by fostering the native system of caste, and a large amount of compromise in the way of religious observances, induced great numbers to receive the Christian faith. The English, who entered on these missions after the Jesuits, were less anxious to propagate, and many of professing Roman Catholics now in the country is considerable. See Xavier, Francis. The earliest Protestant missionaries in India came from Holland and Denmark. With the latter mission, the eminent scholar, Dr. J. de Vlaer, was one of the first who entered on the field of mission work. The British government, in 1784, increased the missionary establishment by £50,000, and in 1854, by £50,000. The mission now in India has a yearly income of £50,000; £95,100; the latter; in the Madras presidency, £38; and in the Bombay presidency there are five civil hospitals, and several government dispensaries.

The railways now in operation, or in course of construction, are the East Indian, Madras, Great Indian Peninsula, Great Southern of India, Bombay-Baroda and Central India, Eastern Bengal, Sind and the Punjab;—giving, when completed, a grand total of 5,850 miles. On the 30th June 1860, 1,745 miles were open for traffic. Some of the bridges and viaducts on these railways are amongst the finest structures in the world.

There is a weekly communication between England and India by the overland route east of Egypt and the Persian Gulf. By going overland to Marseille, thence by steamer and railway to Alexandria and Suez, and thence again by steamer, the journey from London may be accomplished to Bombay in 20—25 days, and to Madras in about a month. The French Messagerie Imperiale have also lately established a new monthly steam-packet service between Marseille and India. Another and more speedy route is proposed via the Euphrates Valley and the Persian Gulf.

Roads.—A grand trunk road extends from Peshawur to Calcutta, a distance of 1,400 miles. In Bengal, there are 11 imperial trunk roads already constructed, or in course of construction, a total aggregate length of 2,000 miles; also 1,100 miles of imperial branch roads, and more than 600 miles of 'feeders' projected. Tramways in connection with the railways and river-transit are about to be formed. A great trunk road from Lahore to Calcutta, 2,880 miles, estimated to cost more than a million sterling, is in progress, and will be an engineering work of no ordinary grandeur and utility. 'It passes,' says Arnold, 'upon 103 great bridges, and 459 smaller ones, penetrates the heart of six mountainous systems, and crosses on immense embankments the marais of two great rivers.' The road sanctioned by Lord Dalhousie, from Kalki, near Umballa, to Simla, and thence to Sobraon, with branches to the holy stations and cantonments, is an undertaking of extraordinary magnitude.

Canals and Irrigation.—Rapid communication and a fully developed system of irrigation are still the two great wants of India. Canals have been extended in the waters of both the Ganges and the Jumna. See Ganges Canal. The Ganges gives more than 800 miles of water-curse; the West Jumna, 425; and the East Jumna, 153. The famous Bar Diab Canal, between the Sutlej and the Ravi, Lord Dalhousie's gift to the Punjab, will altogether be 466 miles long; the main line extending to 247 miles, and the Lahore, Kussur, and Sobharn branches, to 219 miles; more than 50 miles are completed. The total cost of this magnificent work is estimated at £1,500,000. The profits on all works of public utility in India are very large.

Telegraphic Communication, which now extends over 11,000 miles, was started during the administration of the Marquis of Dalhousie. It is probable that daily telegraphic communication between London and Calcutta will be shortly established.

Postal Communication extends, in India, over 43,570 miles. The rate of postage, which, in the year 1854—1855, was reduced to half an anna, or 1/24 farthings, for a single letter, is lower than in any other country.

The Public Works Department undertakes the construction of military and civil buildings, agricultural works, including irrigation canals, and embankments, also roads and bridges.

347
In the year 1859—1860, the expenditure of this department was £12,150,620, of which £7,206,999 were spent on railways, £172,043 on the electric telegraph, and £4,780,578 on miscellaneous works.

A trigonometrical survey of I. has for some time been in progress, and has already extended over about two-thirds of the country.

Commerce.—The commerce of I., which every year assumes vaster proportions, is capable of almost indefinite extension. According to the returns of 1878, the exports of the country were merchandise, £24,265,140; treasure, £16,356,963; total, £40,622,103.

And the exports for the same year amounted to: merchandise, £27,960,203; treasure, £29,007; total, £28,969,210. I. takes more British goods and manufactures than any other country in the world except the United States of America. About £70,000,000 sterling are now invested in Indian undertakings of a public character.

Colonisation.—In the strict sense of the word, colonisation must ever be impracticable in India on account of the unfavourable character of the climate, for the European race settled in the country rapidly degenerates, and in a few generations becomes effete, and bodily and mentally enervated. A constant stream of Indian capital, however, and fresh directing energies in its application, is the great want, and what would secure, as nothing else can, the development of its unlimited resources. Indigo and sugar factories, and coffee and tea plantations, have been the principal undertakings in which independent British capital and energy have been hitherto embarked, and the results have been most satisfactory. The failure of the American cotton supplies of British capital, however, and the fresh directing energies in its application, is the great want, and what would secure, as nothing else can, the development of its unlimited resources. Indigo and sugar factories, and coffee and tea plantations, have been the principal undertakings in which independent British capital and energy have been hitherto embarked, and the results have been most satisfactory.

The story of the Indian cotton supply is a marked instance of the attention which India has paid to this subject. Doubtlessly, India could supply Great Britain with all the cotton she needs; but confidence is required to engage in the speculation of raising it, owing to the uncertainty of the present demand. However that may be, the cotton, wool, and camels are fast opening up the country; civilisation is making rapid strides, creating new demands for trade; and a better knowledge of local sanitary laws is doing much to lessen the risks of climate. At the same time, government, by a wise and liberal policy, is going the right way to establish its claims in the good-will of the native population, and thus secure the stability of British administration; and the resources of Indian finances to their equilibrium on the principle of reduced expenditure, instead of increased taxation, meets with the approbation of both Europeans and natives. India, therefore, promises before long to offer to capital and energy one of the most profitable and secure fields of investment to be found in any of our colonies or dependencies.

Natural Productions.—Cotton is the most important product of Hindustan. It is estimated that, scattered throughout Hindustan, there are about 24,000,000 acres of land under cotton cultivation. Wool will probably soon become a great Indian staple. The chief supply is from the Himalaya and Afghan regions. Hemp and flax, silk from the high lands, coffee, linseed, tobacco, and indigo, are all valuable productions of British India. The leaves and silver blossoms of the tea-plant are beginning to cover the Himalaya slopes and the hills of the United Provinces, the Nerbudda, the North-Western Provinces, and the Punjab. Great quantities of rice are raised in Southern I. and British Burmah. The Malabar district, Martaban, and Tenasserim furnish thousands of logs of the best teak timber. The cinchona or quinine plant has lately been introduced on the Neighheries with great success, the original plants having been brought over from Peru.

History.—The oldest history of I. is entirely legendary; it is shrouded in mythical narratives, which, though of the highest interest from a religious and archæological point of view, do not enlighten us as to the dates of the personnages concerned, nor as to the reality of the facts which they record. Thus, the solar and lunar dynasties (supposed to have been the direct line of the Brahmanical poetry, the epics, the Mahabharata, and the Puranas, as well as other dynasties, like that of Pradyotya, Simandha, and others mentioned in the Puranas, are, for the most part, purely mythical, and the questions which are asked of them have only a literary sense in which we use this word. The first reliable date to be met with in ancient Hindu history is that of Chandragupta; for he is the king whom the Greek historians call Chandracoetus; and as he was the ally of Seleucus, we may conclude that he reigned about 300 B.C. He belonged to the Manrya dynasty, which contains another distinguished name, that of the king Aoka, who plays a prominent part in Buddhist history, and probably reigned from 263 to 220 B.C.; but since the history of this and other dynasties which reigned in different parts of India up to the time of the great Mogul conquest, concerns more the special student of Hindu antiquity and Indian history than the general reader, we will remark, in conclusion, that, with referring those who take an interest in it to the admirable work of Professor Christian Lassen, the Indische Abhandlungs, where they will not only find the richest material collected in any one work, but also learn to appreciate the difficulties which beset the questions of ancient Hindu history and chronology.

From the Mogul Conquest (1505) to the close of the reign of the Mogul Emperor (Wilson's reign).—The House of Ghizni (1001—1167). The Sultan Mahmoud, sovereign of the small state of Ghizni (q.v.), was the first conqueror who permanently established the Mogul power in India. In 1198, the House of Ghizni became extinct, and the Hindu princes fell one by one before a succession of Mogul dynasties, whose names and dates are as follow: Slave Kings of Delhi (1206—1288).—One of these sovereigns, Altunsh, who ascended the throne in 1211, added the greater part of Hindustan proper to his dominions, and in his reign the Mongol Genghis Khan devastated the north-eastern parts of India. In Baiu's reign (about 1284) the Mongols made a great irruption into Hindustan, but were totally defeated by the monarch's eldest son, the herio Mohammed, who fell in the action. The Khusi and House of Toptak (1288—1412).—In 1290, the Mongols made their third and last great irruption into Hindustan, but were almost annihilated by Zafir Khan, whose name became so proverbial among the Mongols, that when their horses started, they would ask them if they saw the ghost of Zafir Khan. In 1337, during the reign of the last of the Toptak kings, the Tartar Timur, or Tamerlane, sacked Delhi, and proclaimed himself emperor of India. The Syuda (1412—1450). The House of Lodi (1450—1526). To the kings of this dynasty succeeded the Great Mogul or House of Timur (1526—1707). Baber, who had for twenty-two years been sovereign of Cabul, invaded I. for the fifth time towards the end of the year 1525 (see Baber), and after doing battle with Sultan Ibrahim, one of the Toptak's confederates, at Tabard, entered Delhi in triumph, and established himself as emperor of the Mohammedan dominions in I., in right of his ancestor Timur. He died in 1530, and was succeeded by his son Humayun. The celebrated Akbar (q.v.), son of Humayun, became emperor in 1556, and reigned for nearly twenty-five years. His son ascended the throne in 1605, and his grandson, Shah Jehan, in 1627. In 1658, Shah Jehan...
was imprisoned by his son, the famous Aurungzebe (q.v.), who usurped the imperial power. This remarkable man raised the Mogul empire to the highest pitch of greatness and splendour, and was the ablest and most powerful, as well as the most ambitious and bigoted, of his race. The death of Aurungzebe in 1707, weakened the sovereignty of the empire, which had begun a few years before then, proceeded rapidly. A succession of nominal sovereigns, sunk in indolence and debauchery, succeeded one another, till the power of the Great Mogul formed their provinces into independent states; whilst Hindu and Mohammedan adventurers carved out kingdoms with the sword. The dismemberment of the Mogul empire opened a wide field for ambition and enterprise to the nations of Europe. The Venetians, the Genoese, the Portuguese, and the Dutch had by turns traded with it; and in 1662, the English appeared on the scene. See EAST INDIA COMPANY.

In 1652, Madras was raised into a presidency, and in 1668, the island of Bombay—which was the dowry of Charles II.'s queen, the Infanta Catherine of Portugal—was transferred by the crown to the Company, by the Act of Settlement. Nadir Shah, in 1738, who sacked Delhi, slaughtered its inhabitants, and carried away the Peacock Throne, and vast treasure, hastened the fall of the Mogul empire.

1710—1761.—Great jealousy existed between the English and French, who had also established themselves in India. On the declaration of war between England and France, hostilities commenced in the Madras presidency, nor were they terminated by the peace of Aix-la-Chapelle, in 1748. The struggle in the Carnatic was continued with ardour, under pretext of supporting the claims of rival native princes to sovereignty. Clive (q.v.), the first and most famous name on that great muster-roll of British soldiers and statesmen who have thrown such lustre on the British occupation of I. Laid the foundation of his country's supremacy in the East. His memorable defence of Arcot in 1751, and his subsequent victories, broke the spell of French invincibility. The next memorable event was the siege and capture of Calcutta, on the 29th June 1756, by Suraja Dowlah, grandson of Ali Verdi Khan, and governor of the declining kingdom of Bengal. The prisoners, 146 in number, were confined in the small garrison prison or Black Hole, of whom only 23 survived till the morning. Clive quickly took command of an expedition fitted out at Madras, recovered Calcutta (1757), and, assisted by Admiral Watson, prosecuted the war with his usual vigour, till after a hollow peace and a renewal of hostilities, Suraja Dowlah was completely defeated by Clive in the memorable battle of Plassey, 23rd June 1757. Meer Jaffir, Suraja Dowlah's commander-in-chief, was placed on themsan by the English, who from this time ruled Bengal as well as Bahar and Orissa.

Public Progress of East India Company (1764—1773).—After the battle of Buxar, fought in 1764 with Sujah Dowlah, the usurping vizier of Oude, the Mogul emperor, Shah Alum, who had previously been in the power of the defeated Sujah Dowlah, claimed the protection of the British. He once more invaded Bengal, in kiey revolts, and they granted them the collectorate or perpituas dwancee of Bengal, Bahar, and Orissa, on condition of receiving the sum of £260,000 per annum. During the subsequent financial invasion of the Province, Nadir Shah, in this and other conditions which they had guaranteed to Shah Alum; and the cost to the Company of maintaining their authority and standing army prevented them from undertaking public works and developing the resources of the country. The Regulating Act was passed in 1773, and a governor-general was appointed. In 1765, Clive purged the Indian government of oppression, extortion, and corruption, and from that, his last visit, dates the purity of the administration of our eastern empire.

Administration of Warren Hastings (1773—1785).—Warren Hastings was the first governor-general of India. A new power, the Supreme Court of Judicial and Civil Judicature, appointed by the Regulating Act, went into operation during his administration. This council arrogated to itself authority exceedingly embarrassing to the governor-general, to whom it was very hostile. Hastings used very unscrupulous, and at times very unjustifiable methods, to get control of the East India Company's exchequer, but, by his energy and talent, he averted dangers that threatened to annihilate the British supremacy in India. The powerful Mussulman sovereigns, Hyder Ali and the Nizam of the Deccan, assisted by French officers, combined with the Marhattas against the English; Sir Eyre Coote broke up the confederacy, and defeated Hyder Ali in 1781. In 1782, the British and French forces (with the support of Talleyrand) invaded the Carnatic, and, after a memorable struggle, restored, and the administration carried on most successfully for the youthful rajah by Colonel Wellesley (afterwards Duke of Wellington). In the famous battle of Assaye, in 1803, he defeated the Marhattas under Scindia; and the victories of Lord Lake in Northern India also were considered the dominions of the Company. The policy of the Marquis Wellesley was, however, too religious to suit the views of the East India Company, and he was superseded by Lord Cornwallis, who only returned to I. to die. Lord Minto succeeded from 1806 to 1813.

Nothing of much importance occurred until the Marquis Wellesley became governor-general (1813—1823). He waged war against the Pindaris, who were entirely suppressed. He had previously defeated the Gurkhas; and before the close of his brief administration he dispelled the British power supreme in India. The civil administration of the Marquis of Hastings was directed to theamelioration of the moral condition of the people of India.

849
The next administrations were those of Earl Amherst and Lord William Bentinck. The first was signalised by the Burmese war, the second by the suppression of sutti and the Thug. This government, as the chief by his unjustifiable and disastrous Afghan policy, ending in the horrible massacre of British troops in the Khyber Pass. See Afghanistan, 1842.

_Earl of Ellenborough_ (1842—1844).—The 'army of retribution' proceeded to Cabul soon after Lord Ellenborough took the reins of government. Cabul was sacked, several public buildings razed to the ground, while the conquered city was evacuated. The conquer of Sind by Sir Charles Napier, followed by its annexation, also belongs to this administration.

_Sir Henry Hardinge_ (1844—1848).—Lord Ellenborough having been recalled by the East India directors, from alarm at his martial tendencies, Sir Henry Hardinge was sent to take his place. The action of the new governor-general was, however, soon diverted from works of peace, to do battle with the rebel forces of the Sikhs. Even before the death of our ally, Runjeet Singh, in 1848, the Punjab had been in a state of disorganisation. The Sikhs, uneasy at our conquests in Sind and Gwalior, and remembering our disaffection at Cabul and the Khyber, determined to evacuate the city. The Sikhs were considered imminent. The first Sikh war commenced on the part of the Punjabese by the passage of the Satluj, and was followed by the terrible battles of Deelon, Burman, and Sobraon, in which, after very hard fighting, the Sikhs were defeated with great slaughter. The war resulted in a British resident and British troops being stationed at Lahore, although the 'boy-prince,' Duleep Singh, was reached by Mahomedan states, the Jullundur Doabs, and the alpine region between the Basa and the Satluj, were annexed.

_Marquis of Dalhouse_ (1848—1855).—The administration of the Marquis of Dalhousie consummated a policy and closed a period, and the centuary of the Company's empire has few so rich in events, and rife with consequences. Beneath his rule, the territory of 'the British merchants trading to the East' received its latest extension; and at his departure the bulk of their power verged to a short retirement. It is memorable for the commencement of superb public works, cheap uniform postage, railways, telegraphs, improvements in government, and social prosperity. In 1852, General Havelock entered the scene of victory, forming the crowning glory of 21st February, 1849, a second Burman war (finished in 1852); and the annexation of four kingdoms, the Punjab, Pegu, Nagpdr, and Ouden.

_Frederick Canning_ (1856—1862).—When Lord Canning took the reins of government, everything promised a reign of peace and prosperity; but it was only the treacherous calm—the barra choop, or great silence—that preceded the tempest. With the early days of 1857 came the first manifestations of the storm that was to sweep over so large a portion of British India. At the commencement of the year, chupatties (cakes of flour and water) were circulated merrily through the North-west Provinces; a kind of political-religious encyclical letter from the Shah in Shah, the head of the faithful in the East, was found in the tent of the Shahzada at Mohunrah, appealing to the faithful to exterminate the Pervengers; reasonable placards appeared at Delhi, and other suspicious occurrences gave warning of Mohammedan disaffection or conspiracy. The Enfield rifle and its greased cartridge was at this time put into the hands of the sepoys without explanation or precaution; and General Anson, the commander-in-chief, snubbed caste, and was against all concession to the 'beastly prejudices' of the natives. The first actual demonstrations of a mutinous spirit broke out at Dumlool (January), Berhampore (February), and Barrackpore (March), where the native soldiers refused to touch the greased cartridges; but the grand centre of the outbreak was Meerut (March 22 miles from Delhi). Here we find the 31st Regiment, the 3rd Dragoon Guards, with the battle of Her Majesty's 89th Rifles, and other European troops, amounting to about 1800 men, besides sappers and miners, and about 2000 native soldiers. On the 23d April, the skirmishers of the 31st Cavalry, on parade, refused to touch the new cartridges, although permission was given to break off the end with the fingers. The 85 mutineers were tried, found guilty, and sentenced to various terms of imprisonment. The parade when the troops were trooped was held on the 9th May, but the punishment only maddened and infuriated the native troops, for within six and thirty hours, Meerut was a scene of bloodshed and desolation. On the evening of the next day, the native troops rose in the most furious manner, and, taking possession of the jail, shot down their officers, and the doomed station was given up to conflagration and massacre. The military authorities, taken by surprise, were paralysed. The commandant was not a leader to the European soldiers, and until too late attempts were made to put down the revolt, or to stop the march of the mutineers to Delhi. The outbreak at Meerut was the crisis of the rebellion. Its prompt suppression was only due to the conduct of the Field-Marshal, whose management involved the fall of Delhi, the sacrifice of thousands of lives, and the temporary triumph of the sedition. The next day, the 11th May, the Meerut mutineers reached Delhi. There they were met by the native troops, who received them with great slaughter. The city fell into their hands, but was retaken by General Archdale Wilson the following September. At the end of June, General Wheeler was forced to surrender to Nana Sahib at Cawnpore, and, in spite of the presence of safe conduct to 'Allahabad, all the men were immediately massacred. The women were butchered on the 15th of July by order of the Nana, when he heard of Havelock's march from Allahabad, which began on the 7th of the same month. Meanwhile the mutiny seized upon the spot, and reached Ouden. The Europeans in the Residence at Lucknow were besieged on the 30th of June by an enormous horde of infuriated mutineers. Five days afterwards, the pillaging and massacre commenced; a second Sikh war (ending in the treaty of Panipat), and the crowning victory of Gwalior, 21st February, 1849, a second Burman war (finished in 1852); and the annexation of four kingdoms, the Punjab, Pegu, Nagpdr, and Ouden.
to besiege it, and on the 17th the city was again in complete possession of the rebels. Central India was reduced by Generals Rose, Roberts, and Whitlock. Jhansi was re-occupied by the 4th of April. The surrender of Calpi and Gwalior followed; and the rebels suffered further by the death of the Rani of Jhaut, the best and bravest of their leaders. Bareilly, in Rohilkund, was taken in May; and by June 1858, no city or fortress of any importance remained in the hands of the mutineers. Oudh was entirely reduced by the beginning of the year 1859. The able rebel leader, Tantra Topper, was at last taken, tried by court-martial, and hanged. During the mutiny, valuable assistance and protection were received from many native chiefs. Rewards and honours were in consequence bestowed upon Scindia, the Maharajah of Gwalior; Holkar, Maharajah of Indore; on the Nizam of Hyderabad, and many others. Throughout the mutiny, natives of I., princes, servants, and sepoys, were found on the side of the British. The 15th, 48th, and 71st regiments of native infantry at Lucknow remained true to their salt, in spite of almost irresistible temptation; while in the Punjab a band of faithful sepoys were formed into an efficient body of Indian artillery. Faithful to the House of the British and the religion of the United Nations in the hands of political schemers, and such an experiment as that of the greased cartridges was only desired to fire the train of craftily laid treason. The trial of the king of Delhi resulted in his conviction as 'a false traitor to the British government, and an accessory to the massacre in the palace.' It was the fate of the last representative of the East India Company to sentence the last Great Mogul and heir of the House of Timur 'to be transported across the seas as a felon.' He was transported accordingly, accompanied by his queen and son, to Tonga, in Pegu, where he died in 1862.

The end of the great Company, and the proclamation of the British sovereignty, was celebrated by the erection of a colossal statue of Queen Victoria on the 1st November 1858, which has been already alluded to. As a result of this, the financial condition of the country is completely changed. Natives of the higher class are nominated to seats in council at each presidency, and a native magistracy has been established; in short, a new maxims has obtained in the administration of the country—viz., that 'India should be ruled for the Indians, and that no imperial necessity can be stronger than imperial obligations.' For further information upon I., the following works may be consulted with advantage: The History of British India, by James Mill, Esq., with notes and additions by Horace Hayman Wilson, M.A., F.R.S (Lond. 1858); History of the British Empire in India, by Edward Thornton, Esq. (Lond. 1861); The Indian Empire, by R. Montgomery Martin, Esq.; The Progress and Present State of India, by Montgomery Martin (Lond. 1862); The History of the Indian Revolt, published by the Messrs Chambers in 1859; The Punjab and Delhi in 1857, by the Rev. J. Cable-Brown, Esq., New ed. (1861); A History of the Mutinies in Os-Oule and of the Siege of Lucknow Residency, &c., by Martin Richard Gubbins (Lond. 1858); The Marquess of Dalhousie's Administration of British India, by Edwin Arnold, M.A. (Lond. 1862).

INDIA, FRENCH, comprises, at the present time, the following settlements:

INDIA RUBBER. See CACOCHOOCH.

INDIAN ARCHITECTURE. The styles of art which have existed at different times in India, as in other countries, vary with the religion prevalent at the time. The earliest faith of which we have any account is Buddhism, and the earliest architectural monuments is that of Buddhism (q. v.). About 250 B.C., Asoka, a powerful monarch, became a strenuous supporter and propagator of Buddhism, and to his zeal we owe the oldest architectural remains of India. From his time to the present day, the sequence is unbroken, and one of the most notable features of Indian Buddhist architecture can be most distinctly traced either in India or in Ceylon, Java, and Tibet. The whole subject is as yet, however, imperfectly illustrated, the best account of the Indian styles being that contained in Mr. Butter's Handbook of Architecture, and his other works. The Buddhist remains are of two kinds: 1. Commemorative monuments, called Topes or Stupas (q. v.); the earliest stupas are single pillars, bearing evident traces of a western origin, and thus affording a clue to the history of Indian art. 2. Temples (chaityas) and monasteries (viharas). Of the chaityas and viharas, no built examples remain; they are all excavated out of the solid rock. There are no less than 40 or 50 groups of these monuments, each group comprising from 10 to 100 distinct excavations. A few of these belong to other religions, but the great majority are Buddhist, and nearly the whole are monasteries, not over 20 to 30 being temples. The oldest are at Bahar and Cuttack in Bengal (200 B.C.), but they are few in number, sixteenth of the caves being in the Bombay presidency. This probably arises from the nature of the material in which they are cut, the eastern caves being in a hard granite, and those of the west being in a very uniform and comparatively soft amygdaloid. The latter date from the beginning to about the 10th c. of the Christian era. The cave-temple at Karli is one of the largest, and is of a good style. See section in art. BUDDHA. In plan and general arrangements, it strongly, though no doubt accidentally, resembles a Christian basilica, with nave, aisles, and vaulted roof, and an apse with the shrine in the place of the altar. There is also an outer hall or atrium, and a gallery like the roof-loft. On the roof, are numerous wooden ribs, attached to the vault; these and other portions indicate that the building from which the cave was carved was wooden, which may account for the absence of earlier built examples. This cave is 126 feet long, 45 feet 7 inches wide, and 40 to 45 feet high. The vihara or monastery caves are very numerous, as was required by the enormous number of Buddhist priests. The oldest and simplest examples are in Bengal, but the finest are in Western India. They 321
Indian Architecture

Consist of a central hall, with cells round three sides, and a verandah on the fourth side, next the open air; opposite the central entrance, there is usually a large cell or shrine, containing an image of Buddha. There are fine caves at Ajunta, Bauagh, &c., many of them beautifully carved and painted. The pillars are most elaborately ornamented, and have the bracket capitals which distinguish all Indian architecture. From the absence of any built example, there has been great difficulty in forming a correct idea of the exterior of the buildings from which these caves were copied. By following the style into other countries where the religion has prevailed at different times, Mr. Fergusson has been able to trace it up to the present day, and to establish historically the probable external appearance of the early Buddhist architecture.

The temple of Brambanam, in Java, seems to show the original form of built cells. They are quite central and arranged in a square round a central temple—evidently suggesting the arrangement in the caves at Ajunta. Some rock-cut temples which have an exterior (at Mahavellipore), show the cells attached to the main building. In Brambanam, the monastic system still prevails, the monasteries, which are of wood, are built in stages in a pyramidal form. The temple of Boro Buddha (q.v.), in Java, has a similar arrangement, consisting of a large number of cells or niches in the place of being occupied by priests, they are filled with cross-legged Buddhas, a conversion quite common in later Hindu architecture. In many styles of architecture, the niches or other subordinate parts are frequently copied on a small scale of the façade of the building itself. Thus, for instance, the windows with pillars and pediments in classic architecture, are a repetition of a temple end. The niches inside the caves, containing statues of Buddhist saints, are in a similar manner imitations of the main façade. In the same way externally, the Burmese pagodas and Hindu temples are ornamented all over with models of the buildings themselves.

Mr. Fergusson has thus traced, in fuller detail than our space will allow, the transformations that have taken place in Buddhist architecture, which, whatever its artistic qualities may be, has at least the very interesting feature of being a style which has existed from 200 years before Christ up to the present day.

The other styles of Indian architecture are illustrated by the temples of the Jainas and those of the Hindus. The former seems to have been an imitation of the Buddhist temples without the cells for the priests. Their religious structures consist of a sanctuary surrounded by a spire; in front of this, a-pillared vestibule, with a dome, and round the whole an arcaded enclosure, with cells all round, containing images. The cells are also surrounded with spires, and the arcades with domes are often repeated to a considerable number within one enclosure. The most striking feature of this style is the dome, which is constructed by horizontal joints with regular arches. The domes, with the pillars, bracket capitals, &c., are all elaborately decorated.

Hindu architecture is divided into two styles—northern and southern. All the examples are southern, and are found south of Madras. The temples consist of the temple or vimana, in front of which is the pillared porch or mantopa, the gate pyramids or gopuras, forming the entrances to the enclosure, and the pillared halls or choultries. In the south, the temple is always pyramidal, and in many stories; in the north, the outline is curved, and in one story. The finest example is the pagoda of Tanjore. It is 82 feet square at base, and 14 stories, or about 200 feet, in height.

The gopuras are similar to the pagodas, but oblong in place of square.

Gopura, or Gate:
Leading into the enclosure of the temple at Seringham.

The pillared halls are very wonderful structures, containing sometimes as many as 1000 columns, and as these are all elaborately carved, and all different, the labour of their construction must have been enormous. They are used for many purposes connected with Hinduism, their most important use being as nuptial halls, in which the mystic union of the divinities is celebrated. The general arrangement of these halls sometimes produces a good effect; but from their flat roofs, they cannot equal the beauty of the domed arcades of the Jains. These buildings are of various dates, from the commencement of the Christian era to the last century, and it is remarkable that the oldest examples are the finest—the style growing gradually more and more debased, till in the present day, it has become, like the religion, a mass of absurdity and obscenity. The celebrated rock-cut temple, called the Kylas, at Ellora (q.v.), belongs to this style.

When the Mohammedans conquered India, they imitated the style of the country in their mosques, and afterwards the Hindus borrowed from them, and thus a mixed style was created, which, in the palaces, tombs, &c., of the native princes, produces picturesque effects. The Mohammedans also covered the country with specimens of their Moorish style, which will be treated under Saracen Architecture.

Some of the finest buildings of India are the ghats or landing-places, with their broad flights of steps; the reservoirs of bowloes, and dams, all ornamented with temples, kiosks, stairs, &c.; but our space will not permit us further to describe them. There is one very remarkable fact connected with Indian architecture, viz., that although the form of the arch is constantly used—in domes, arcades, &c., especially in the style borrowed from the Moslems—yet the radiating arch construction is never adopted. The architraves are supported on bracketed capitals, which project, bracket over bracket, till the space is spanned by one lintel. This leads to many beautiful results in the early styles, and in the later mixed style, the bracketed cornices are amongst its finest features.
INDIAN ARMY—INDIAN TERRITORY.

INDIAN ARMY. See East India Army.

INDIAN CORN. See Maize.

INDIAN FIG. See Prickey Pear.

INDIAN FIRE. A bright white signal-light, produced by burning a mixture of 7 parts of sulphur, 2 of Resinol (q. v.), and 24 of nitre.

INDIAN GRASS MATTING, or INDIAN MATTING, a kind of matting imported in large quantities from Calcutta, is made from a species of PAPPUS (q. v.). P. Fangorei, called Madookari in India, is there very abundant. The stalks of the plant, when green, are split into three or four pieces, which, in drying, contract so that the edges come almost into contact; and when woven into matting, they shew nearly the same beautiful shining surface on both sides.

INDIAN INK. The cake of this substance, which is a mechanical mixture, and not, like the true inks, a chemical compound, are composed of lampblack and size or animal glue, with a little perfume. The lampblack must be remarkably fine, and is said to be made in China by collecting the smoke of the oil of lamp-castor (about 2 per cent.) is also found in the ink made in China, and is thought to improve it. This substance is used in that country with a brush both for writing and for pointing upon paper of native manufacture, while, in this country, it is extensively employed for designs in black and white, and all intermediate shades of colour. Much curious information on this pigment may be found in Merimee's treatise, De la Peinture à l'Encre.

INDIAN OCEAN, one of the five grand divisions of the universal ocean, is bounded on the S. by a line drawn from the Cape of Good Hope to the most southerly extremity of Tasmania or Van Diemen's Land. Its other limits, reckoning from the last-mentioned point, are Van Diemen's Land, Australia, the Indian Archipelago, Farther India, Hindustan, Persia, Arabia, and Africa. Gradually narrowing from south to north, the I. O. forks at Cape Comorin into the Bay of Bengal on the east, and the Arabian Sea on the west, the latter again branching off on both sides into two arms, the Gulf of Cambay, off the coast of central India, the Red Sea, which reach respectively the mouth of the Euphrates and the neighbourhood of the Mediterranean. These details exclude the waters of the Indian Archipelago, as belonging rather to the Asiatic than to the Pacific Ocean. As above stated, the I. O. stretches in lat. from 43° 35' S. to 30° N., and in Long., from 18° 29' to 146° 12'. It contains thousands of islands, or rather tens of thousands. Of these, Madagascar is the largest, and at about the same distance from it to the east as the continent of Africa is to the west, lie Bourbon or Reunion towards the south, and Mauritius towards the north. Next in size to Madagascar, and, in fact, the only other island of any considerable magnitude, is Ceylon. As a channel of commerce, this ocean would appear to have been the first to find a place in history, inasmuch as the earliest voyage recorded beyond the land-locked Mediterranean—that of Sinon or Sinth—seems extended farther than the Straits of Beh-cl-Mandeb. In this respect, it virtually maintained its superiority during fully 2000 years, being habitually traversed in the line of the crow's flight, between Arabia and Hindustan, which is the terrestrial parallel of the N. by Z and W. by S. the chief articles of commerce are spices, silk, pepper, cotton, indigo, rice, and coffee. The navigation of this ocean, however, is attended with many dangers, as the Gulf of Cambay is exposed to the influence of亍e monsoons of the northern part of the I. O., blowing, as they do, alternately from the south-west and the north-east.

INDIAN SHOT (Canna Indica), a plant common in almost all tropical countries; a herbaceous perennial, with a creeping root-stock (rhizome), and a simple stem, divided by the cohering bases, the I. O. leaves large, tough, ovate-oblong leaves. It belongs to the natural order Marantaceae. It derives the name I. S. from the seed, which is hard, round, and about the size of a very small pea, and is sometimes used as shot. The seed yields a beautiful red colour. The root-stocks are very large, spongy, and jointed, and are used in Brazil for emollient poultices in tumours and abscesses. The root-stocks of some of the other species of Canna are more valuable, yielding the starch called Tous-les-Mois (q. v.),

INDIAN TERRITORIES, a phrase of vague meaning, is peculiar to the geography of America. Originally and naturally, it indicated such portion of each country as had not yet been colonised, a portion which, of course, was constantly diminishing. In this sense, therefore, the words necessarily varied in extent of application from year to year. In 1821, however, the I. T. of British America were defined by statute as comprising only the unsettled wilder parts of the colonies beyond the Hudson's Bay Company's chartered domain, which was itself generally held to be identical with the basins of all the feeders of Hudson's Strait and Hudson's Bay. Due west, this vast region bordered on Russian America; as far north as the parallel of 34° 40' southward to that of 42°, it touched the Pacific Ocean. Subsequently to 1821, this maritime section was partly ceded to the United States, and partly erected into the colony of British Columbia, so that the I. T. of the present day now comprise the sea excepting on the ice-bound shores of the north. Within this limited range, too, they have practically lost their statutory character, being virtually released (see Hudson's Bay Company) from the restrictive system of trading licences. Hitherto, perhaps, the change has been merely nominal, for, independently of the influences, moral and physical, of long possession, the Hudson's Bay Company finds, in distance and seclusion, a guarantee stronger than any parliamentary title. If competition is likely to be powerless for years to come, colonisation is sure to be so for ages under the combined prohibitions of soil and climate. The I. T. stretch in N. lat. from about 55° 1' to 59° 30', and in W. long. from 106° to 103° to the international boundary between Russia and England of 141°. They consist chiefly of the valleys of the Back, the Coppermine, and the Mackenzie. Beyond all the analogies of civilised communities, the native population is incredibly sparse and scanty, certainly not exceeding, at an extravagant estimate, 10,000 in number, exclusively engaged in hunting and fishing; while less than 500 strangers of every kind are scattered abroad in hovel-like forts, hundreds of miles distant from each other. The I. T. form part of the diocese of Rupert's Land, established in 1849; but it is only since 1858 that they have actually become the scene of missionary operations.

INDIAN TERRITORY, a country reserved by the government of the United States for the Indian tribes removed west of the Mississippi, and those living there. It lies between 33° 30' and 37° N. lat., and 94° 20' and 103° W. long., being 370 miles long by 230 wide, with an area of 74,127 square miles. It is bounded on the N. by Kansas and Missouri, on the W. by Arkansas, S. and W. by Texas, from which it is separated on the south by the Red River. It is a beautiful country, with vast fertile plains, watered by innumerable streams, including the Red River, the Arkansas, and their branches. The

553
INDIAN YELLOW—INDIANS.

climate is genial, producing cotton, tobacco, maize, \textit{etc.}, and \textit{h. frutta}. Its population of 120,000 consists of Cherokee, Creeks, Seminole, Choctaw, Chickasaw, and remnant of smaller tribes. Provided with schools, missionaries, and annual payments from the United States government for the lands they have abandoned, they are well advanced in culture and improvement. The young men are educated in public seminaries, and many of the Indians own negro slaves, and cultivate large plantations.

INDIAN YELLOW, or PURREE, is a colouring matter highly esteemed by artists. It is exported from the East Indies in masses of three or four ounces in weight, which are of a dark-brown colour purplish, but of a bright orange yellow in the interior. Nothing certain is known regarding its origin, but it is generally believed to be a urinary sediment of the camel or buffalo, after the animal has fed on decayed and yellow mango leaves. Its odour is peculiar, and resembles that of castoreum. This substance consists chiefly of the magnesium salts of an acid termed \textit{pururic or eucanthic acid}. It is almost insoluble in cold water or alcohol, but is soluble in hot alcohol and in ether; it also dissolves freely in boiling dilute hydrochloric acid, from which stellate groups of acicular crystals of eucanthic acid (\textit{HOC}_4\textit{H}_2\textit{O}_3\textit{O}) are deposited on cooling. Alkaline solutions dissolve this acid, and form a yellow solution of eucanthic acid, when mixed with the solutions of the salts of the earths, gives brilliant yellow, sparingly soluble precipitates, and, with acetic acid of lead, it forms a yellow soluble lake.

By dry distillation, this acid yields a yellow crystalline sublimate of \textit{pururene or eucanthine} (\textit{C}_4\textit{H}_8\textit{O}_3\textit{O}), water and carbonic acid being evolved; and, with nitric acid, it yields several nitrogenous bodies of considerable interest, in purely chemical point of view, but of no practical importance.

INDIANA, one of the United States of America, organised in 1816, with a governor and legislature, extends from 37° 47' to 41° 48' N. lat., and from 84° 49' to 88° 2' W. long., having a length of 276 miles, a breadth of 40 miles, and an area of 33,822 square miles, or 21,637,760 acres. It is bounded on the N. by Michigan state and lake, E. by Ohio, S. by Kentucky, from which it is separated by the Ohio river, and W. by Illinois. The state is divided into 94 counties. The capital is Indianapolis, near the centre, and its chief towns are Evansville, New Albany, Madison, Vincennes, Terre Haute, Lafayette, Fort Wayne, and its only lake-port, Michigan City. The population in 1800 was 4,875; in 1810, 24,329; in 1820, 147,178; in 1830, 313,031; in 1840, 685,866; in 1850, 988,416; and at the census of 1860, 1,350,941, of which nearly half are immigrants from other states, and from Germany and Ireland. The state is level, with sluggish streams and great prairies. It is chiefly drained by the Wabash river and its branches. There are 7,700 square miles of coal, portions of which, on the Ohio, are coal of equal quality. The soil is of wonderful fertility, and the climate is like that of the south of France, with colder winters, and the hills on the Ohio are covered with fine vineyards. The staple productions are wheat, maize, cattle, swine, tobacco, fruits, wine, \&c. There are over a thousand miles of turnpike roads, besides the canals, and the Ohio river. It is divided into 94 counties, and the public seminaries are situated at Lafayette, Vincennes, Evansville, and Fort Wayne. Vincennes, on the Wabash, was settled by the French in 1792; at the close of this period, the settlements were disturbed by Indian hostilities; the Indians were defeated in 1811 by General Harrison, and the territory was peopled with great rapidity. The sale of lands from 1830 to 1840 was over 9,000,000 acres.

INDIANAPOLIS, a city and capital of Indiana, United States of America, is built on the west fork of White river, near the centre of the state, 109 miles north-west of Cincinnati. It is a regularly built and beautiful city, with a handsome state-house, courthouse, jail, and state arsenals for the blind, deaf and dumb, and insane. It has a university, 2 female colleges, 30 churches, 7 banks, 9 printing-offices, 11 hotels, and wooden factories, iron-foundries, planing-mills, and flour-mills, with abundant water-power. It is the terminus of eight radiating railways. In 1840, the population was 2092; in 1860, 30,000.

INDIANS, American, the collective name now generally given to the various nations and tribes inhabiting North and South America, at the time of their first discovery by the Spaniards, and to such of their descendants as survive at the present day. The name of Indians was first given to the natives of America from the mistaken notion of the early voyagers, Columbus himself included, that the newly found continent was in reality Asia. This was soon shown to be an error; but the name of Indians, thus wrongly applied to the inhabitants, continued to be used in every narrative of voyage and discovery, and has descended even to our own times, only that we now qualify it in some measure by speaking of them as American Indians. In the classification of Blumenbach, the American Indians are treated as a distinct variety of the human race; but in the three great divisions of mankind laid down by Dr Latham, they are ranked among the Mongolids. Other ethnologists also regard them as a branch of the great Mongolid family, which, at a remote period of the world's history, found its way from Asia to the American continent, and there remained for thousands of years separate from the rest of mankind, passing meanwhile through various alternations of barbarism and civilisation. Morton, however, the distinguished American ethnologist, whose name is immortalised in the name of the capital of Indiana and of Giddon, claim for them a distinct origin, one as indigenous to the continent itself as its fauna and flora. 'The American race,' says Dr Morton, 'differs essentially from all others, not excepting the Mongolids of the Old World and of the New, and the Semites, and the Semitic languages, the more obvious ones of civil and religious institutions and arts, denote anything beyond casual or colonial communication with the Asiatic nations; and even these analogies may perhaps be accounted for, as Humboldt has suggested, in the mere coincidence arising from similar wants and impulses in nations inhabiting similar latitudes.' Even Frechard, whose views with respect to the unity of the human race differ essentially from those of Morton and his school of ethnology, acknowledges that, 'on comparing the American tribes together, we find reasons to believe that they must have subsisted as a separate department of nations from the earliest periods on this American continent.' By attempting to trace relations between them and the rest of mankind, we cannot expect to discover proofs of their derivation from any particular tribe or nation in the old continent. The era of their existence as a separate people is dated at 7,000, and their date may be dated as far back as that time which separated into nations the inhabitants of the Old World, and gave to each branch of the human family its primitive language and individuality. Thus, on all hands we find an admission made of the most remote antiquity with respect to the origin of the various
Indian tribes. It is also admitted that between those various tribes, from the Arctic Sea to Cape Horn, there is great diversity of physical structure and personal characteristics than is seen in any other quarter of the globe. There are varieties, it is true, and those sometimes of a very striking kind. The 'Red Men,' as they are called, of the United States and Canada, differ in many respects from the Guaranis of Paraguay, and both from the wild tribes of California, but all exhibit the clearest evidence of belonging to the same great branch of the human family. Upon this point, the testimony of a writer like Humboldt is very important. 'The Indians of New Spain,' says Humboldt, 'bear a general resemblance to those who inhabit Canada, Florida, Peru, and Brazil... Over a million and a half of square leagues, from Cape Horn to the river St Lawrence and Behring's Strait, we are struck at the first glance with the general resemblance in the features. We think we perceive them all to be descended from the same stock, notwithstanding the prodigious diversity of their languages. In the portrait drawn by Volney of the Canadian Indians we recognise the tribes scattered over the savannahs of the Apure and the Carrao.' The same general features exist in both American tribes. The general characteristics of the American Indians are as follows: a square head, with a low but broad forehead, the back of the head flattened, full face, and powerful jaws; checkbones prominent; lips full; eyes dark; and deep set; the hair long, not absolutely straight, thick and wavy, something like a horse's mane, and like that, of a glossy hue; little or no beard—where it does appear, carefully eradicated with tweezers; colour of the human family. Upon this point, the resemblance is very obvious, but looking taller from their erect posture and slender figure; the women rather shorter, and more inclined to obesity, but many of them with symmetrical figure and pleasing countenance; hands and feet of both men and women small.Such as before said, however, there being some hundreds of tribes among the American Indians, there are many departures from these general characteristics, not only in individuals, but entire sects. 'The Indians of the valley of the Missouri is denominated red, that is, of a copper-colour; some tribes are as white as many European nations; others brown or yellow; others are black, or, at any rate, swarthy. The Spanish term for them was the casca,' said Mr. Volney, 'but it very much resembled in colour the negroes of Africa. Anatomists have distinguished what they have termed the American form of the human skull: they were led into this mistake by regarding the strongly marked characteristics of some particular tribes as universal. The American nations are spread over a vast space, and live in different climates, and the shape of their heads is different in different parts. Nor will any epithet derived from their habits of life apply to all the tribes of this department. The native Americans are not all hunters: there are many fishing tribes among them; some are nomadic; others cultivate the earth, live in settled habitations, and of these, a part were agriculturists before the white man arrived. All the various tribes have learned of their conquerors to till the soil, and have changed the ancient habits of their race, which, as we may hence infer, were not the necessary result of domestication and degeneration.' Dr. Prichard appears inclined to the same view, adding: 'Attentive observers have been struck with manifestations of greater energy and mental vigour, of more intense and deeper feeling, of a more reflective mind, of greater fortitude, and more thorough perseverance, more arduous enterprise and all pursuits, when they have compared the natives of the New World with the sensual and

that great diversity of American languages, considered only in reference to their vocabularies, the similarity of their structural and grammatical forms has been observed and pointed out by the American philologists. The result appears to confirm the opinions already entertained on that subject by Mr. Du Ponceau, Mr. Pickering, and others; and to prove that all the languages of the various Indian tribes, of the native inhabitants of America, from the Arctic Ocean to Cape Horn, have, as far as they have been investigated, a distinct character common to all, and apparently differing from any of those of the other continents with which we are most familiar.'

The next question that comes under consideration is: Whence does it arise that, with all this similarity of physical conformation and language, these should have been only two nations among so many millions—namely, the Mexicans and Peruvians—who attained to any high degree of civilisation? When the Spaniards entered Mexico, they found it in a rich, powerful, and warlike nation, living in walled cities, in which were palaces and other sumptuous residences. The Spanish possessed them, and their language, which, long before the year 1534 of our era. A few years later, in Peru, the Spaniards found another nation, also exceedingly rich, numerous, and powerful, with a civilization fully as much extended as that of the Aztecs, yet differing from that in many essential particulars. This was the nation of the Chiquisua, a people, the Spaniards found, who, as an exception, perhaps, to the Aztecs, who professed to have among them evidences of antiquity dating as far back as the year 354 of our era. A few years later, in Peru, the Spaniards found another nation, also exceedingly rich, numerous, and powerful, with a civilization fully as much extended as that of the Aztecs, yet differing from that in many essential particulars. This was the nation of the Quichuas, a people, who were the AyMaryas, whose country had been subdivided by the Incas two or three centuries before the arrival of Pisarro in Peru. Each of these nations—the Mexicans and Peruvians—is considered by Dr. Prichard, to be supposed to have been a mixture of races, as far as they have been investigated, by the original barbarians who founded the two nations, and the original nations or races, who lived in the regions of North America and South America. The nation of the Mexicans, who were the Aztecs, is supposed to have been a mixture of the nations of the Mississippi, and the nations of the Hudson's Bay Territory, California, and Patagonia. In Central America, however, there have been found remains of architecture and other traces of civilization, which would seem to date back to a more remote period than that of the Mexican or Peruvian empires. The artificials also exist in the valley of the Mississippi and elsewhere throughout America, supposed to be the work of the ancestors of the present wandering tribes. If so, there may be some truth in the theory of Dr. Martinus, a distinguished German ethnologist, that the nations of the New World are not in a state of primitive barbarism or living in an original and uncultivated nature, but that they are, on the contrary, the last remains of a people once high in the scale of civilization and mental improvement, now almost worn out and perishing, and sunk into the lowest stage of decline and degradation.' Dr. Prichard appears inclined to the same view, adding: 'Attentive observers have been struck with manifestations of greater energy and mental vigour, of more intense and deeper feeling, of a more reflective mind, of greater fortitude, and more thorough perseverance, more arduous enterprise and all pursuits, when they have compared the natives of the New World with the sensual and
INDICTMENT—INDICTMENT.

volatile, and almost animalised savages who are still to be found in some quarters of the old continent. The Mexicas and Peruvians, and the blacks of the sunny and unsoiial character, by the proud apathetic endurance, by the feeble influence of social affections, by the intensity of hatred and revenge, and the deep malice-concealing dissimulation so remarkable amid the dark solitudes of the American forests.

Again, M. d'Orbigny has classified the Indians of North America under three great groups, viz., the Andian group, the Medederranean group, and the Brasilia-Guarian group; and these he subdivides into thirty-nine distinct nations; viz., 1. Quichua; 2. Ayamara; 3. Chango; 4. Atacana; 5. Patagocas; 6. Kuechmayas; 7. Marayna; 8. Aposlita; 9. Araucanian; 10. Fuenlian; 11. Patagonian; 12. Pudeche; 13. Charrua; 14. Mopobii; 15. Mataguayo; 16. Albugones; 17. Lengua; 18. Rameaux; 19. Chiquito; 20. Saravacas; 21. Otuke; 22. Curusayas; 23. Corvaceas; 24. Curaveas; 25. Tapius; 26. Curunecasa; 27. Paiconeca; 28. Corebecas; 29. Motoxo; 30. Chapuracas; 31. Itonama; 32. Canichanas; 33. Movima; 34. Cayuvavana; 35. Paesuens; 36. Botocudus. Other classifications have been attempted, but all more or less arbitrary. Morton is content with two grand divisions, viz., the 'toltecan Nations' and the 'barbarous Tribes;' the former embracing the ancient Mexicas, Peruvians, and all the rest of the uncivilised or semi-civilised tribes from the extreme north to the extreme south. Of the Toltecas, whom he supposes to have been the builders of the remarkable series of mounds found throughout North America, Dr Morton collected as many as 213 skulls, taken from the oldest burial-grounds; and of the Barbarous Tribes, 211 skulls, partly modern and partly ancient. Accurate measurements of these, together with many curious particulars, are given in his celebrated work, the 'CruxisAmericana.'

With respect to the numbers of the Indian nations and tribes as at present existing, no perfectly accurate statement can be given. Those in North America, however, may be fairly set down as amounting to between 5,000,000 and 6,000,000, and those in South America as reaching about 7,000,000. Of the former, only about 400,000 belong to the United States, about 1,000 to the British possessions, 4,000,000 to Russian America, and the rest, being the great bulk, to Central America and Mexico. Of the United States' Indians, several thousand have been reclaimed from barbarism to habits of order and civilisation, with respect to whom, Mr Schoolcraft, in a report dated November 1854, speaks in the following hopeful terms: 'Some twenty of the tribes have more or less fully embraced agriculture, raise large stocks of cattle and other domestic animals, and have adopted the civilised costume. These occupy the new Kansas and Indian territories; four of the tribes, numbering 60,000 persons, have adopted systems of government and written constitutions. All these tribes have been transferred from the wild to the civilised state. No small part of them are the descendants of tribes who occupied the area of the Union on the first planting of the colonies. Much effort and much expense have been incurred with them. They have been under the subject of humanitarian and benevolent care and sympathy during two centuries. To confound them in our policy with the wild tribes—for a moment to suppose that they partake of the habits and feelings of the robbers, plunderers, and murderers of the black plains and mountains, would be the highest injustice. There are men in these reclaimed tribes who are exalted in their feelings, principles, and manners, who acknowledge the best truths of letters, arts, and Christianity, and who live an honour to human nature.'

For more complete information with reference to the Indians of America, on the subjects here only alluded to in the most summary manner, the reader should consult the work of Mr Washington Latham, and Morton, but of Humboldt, Du Ponceau, D'Orbigny, Gallatin, Schoolcraft, Catlin, Pickering, Prescott, Stephens, Tschudi, and Fremont; not omitting the several reports of the United States Commissioners of Indian affairs.

INDICTMENT, a period or cycle of 15 years, the origin of which is involved in obscurity. Connecting the original meaning of the word, viz., 'the imposition of a tax,' with its signification in chronology, several writers have propounded theories explanatory of its origin, none of which, however, are supported by a tittle of evidence. It began to be used in reckoning time, chiefly by ecclesiastical historians, during the life of Athenaius; it was afterwards adopted by the popes, who still continue to use it, and through whose influence it came to be so generally employed during the middle ages, that the dates of charters and public deeds of this era are expressed in indications as well as in years of the Christian era. The time from which reckoning by indications is commenced, is, according to some, the 15th September 312; according to the Greeks of the Lower Empire, 1st September 312; but when this method was adopted by the popes, it was ordered to be reckoned as commencing 1st January 315. The latter, which is now alone used, is called the 'Papal Indictment.' If we reckon backwards to the commencement of the Christian era, it will be seen that 1 A.D. does not correspond to the 1st, but to the 4th year of an indication—since, if we suppose the year of the Christian era 3 to be added, and the sum divided by 15, the remainder will give the position of that year in an indication—e. g., 1863 A.D. is the 6th year of an indication.

INDICTMENT is the name given to the written accusation of crime against a person, and upon which he is tried by a jury. An indictment in England commences with a caption, i.e., a description of the style of the court, which, however, is no part of the indictment; then follows the venire or statement of the place where the crime was committed or the act committed, which is in the name of the jurors, i.e., the grand jury. In Scotland, an indictment is also the accusation on which a prisoner is tried; but it runs in the name of the accused, and the plea, if any, is addressed to the prisoner. In England, a prisoner is not entitled, before trial, to a copy of the indictment or a list of the witnesses.
against him, except in treason; but he can in most cases prove to a copy of the depositions of witnesses, if these were taken before a magistrate, at a trifling expense. But many cases are not inquired into at all before a magistrate, so that this reasonable advantage is not given uniformly in England.

In Scotland, on the other hand, a prisoner is in all cases entitled to have a copy of the indictment given to him fifteen days before trial, and also a list of the witnesses to be brought against him.

INDIES. See East Indies and West Indies.

INDIGESTION, or DYSPERTIA, is a term somewhat vaguely applied to various forms of disease of the stomach or of the small intestines in which the natural process of digesting and assimilating the food is deranged.

The symptoms of indigestion are by no means constant in all cases. There is often anorexia (or want of appetite), but occasionally the appetite is excessive, and even ravenous. Nausea not frequently comes on soon after a meal; while in other cases there is no nausea, but after the lapse of a couple of hours, the food is vomited, the vomited matters being very acid, and often bitter, from the admixture of gastric juices. Bowel actions are often seventeenth centuries common. Flatulence, relieving itself in erucations, is one of the standard symptoms of this affection, the gas that gives rise to this symptom being sometimes evolved from undigested matters in the stomach, and sometimes being apparently secreted by the walls of that viscus. It is very apt to occur in dyspeptic patients if they have fasted rather longer than usual.

Cardiopathy (popularly known as heartburn), Pyrosis (q.v.), or water-brash, and Gastrodyxia (commonly designated spasm or cramp of the stomach, and coming on at uncertain intervals in most severe paroxysms), are other somewhat less common symptoms of indigestion.

The treatment of indigestion is more dietetic than medicinal. The quantity of food which can be dissolved by the gastric juice and intestinal fluids being limited (see Digestion), care should be taken that this quantity is not exceeded; moreover, the meals should not succeed each other too rapidly. Mr Abernethy, who was a great authority on this subject, laid great stress on the principle, that the stomach should have time to perform one task before another was imposed upon it, and he always recommended his patients to allow six hours to intervene between any two meals. With regard to the nature of the food best suited to dyspeptic persons, it may be safely asserted that a mixture of well-cooked animal and vegetable food is in general more easily digested than either kind taken exclusively. Mutton, fowls, and game are the most digestible kinds of animal food, and pork and all cured meats, such as salted beef, ham, tongue, &c., should be avoided. Raw vegetables, such as salads, cucumbers, &c. must also be prohibited. In most cases, dyspeptic persons would probably do well to avoid all stimulating drinks; but in some cases, a little cold, weak brandy and water, or a glass of old sherry, or a little bitter ale, may be taken with advantage. But upon all points of eating and drinking, a sensible patient must be mainly influenced by his own experience. The unquestionable benefit which dyspeptic patients often derive from a visit to a hydropathic establishment is due perhaps not so much to any specific action of the water, as to the well-regulated diet, the withdrawal of the mind from the limits of the scene. A six weeks' or two months' tour among the mountains of Scotland or Switzerland will in the same way often do a dyspeptic patient more good than he could have experienced from any amount of physicking at home.

A few words must be said regarding the mode of treating the most urgent of the individual symptoms. Loss of appetite may be remedied by the employment of bitters, such as quinine, gentian, chicorétta, &c., or of mineral acids, or of both combined. Nausea and vomiting may be treated with hydrocyanic acid, chloriform, and creasote in very small doses. Two or three drops of dilute hydrocyanic acid in an effervescent draught are often an effectual remedy. In intense vomiting, the amount of food taken at a time must be reduced to the lowest possible limit. A tablespoonful of milk, mixed with lime-water, will sometimes remain on the stomach after all other kinds of food have been rejected. There is no better remedy for flatulence than peppermint-water; if it fails, a drop of cajeput oil on a lump of sugar may be tried. When the eructations are attended with an odour of rotten eggs—that is to say, when sulphuretted hydrogen is evolved from the decomposition of matters in the stomach—an emetic is the best cure. The remedies for the pain in the stomach vary with the character of the pain; bismuth, nitrate of silver, and opium are the most serviceable, but should not be taken without advice. A teaspoonful of the aromatic spirit of ammonia in a wine-glass of camphor mixture, often gives instantaneous relief, and if not too often resorted to, can be taken with impunity.

INDIGIRKA, a river of Siberia, in the government of Jakutsk, rises in the Yablonoi or Stavroni Mountains, and after a northerly course, estimated at 750 miles, through a frozen desert studded with a few villages, falls into the Arctic Ocean in lat. 71° N., and long. 158° E.

INDIGO (Gr. Indikon, Indian), a most important vegetable dyestuff, yielding a beautiful blue and very durable dye, the basis also of the best black dye in woollen cloths. It has been used in India from a very early period, and was imported thence by the ancient Greeks and Romans, but was lost to Europe during great part of the middle ages—although the cultivation of the plant and preparation of the dye were described by Marco Polo in the 13th century—until re-introduced by the Dutch about the middle of the 16th century. Its use in England, France, and Saxony was then for a considerable time
INDIGO.

prevented by a strong prejudice against it, arising from the difficulty experienced in fixing the colour. Since this has been overcome, the cultivation of plants producing indigo, long confined to India, has extended to many other tropical and sub-tropical countries, as Egypt, the West Indies, Mexico, Brazil, &c. These plants generally belong to the genus _Indigofera_, of the natural order _Leguminosae_, and sub-order _Papilionaceae_. The keel of the corolla is furnished on both sides with an awl-shaped spur. The species of this genus number at least 150, and are natives of almost all tropical and sub-tropical countries. Of these, _I. tinctoria_ is the species most generally cultivated in India. It is a half-shrubby plant, 2-3 feet high, with pinnate leaves, which have five or six pairs of long-obovate, dull, bluish-green leaves, and racemes of axillary pale red flowers.

The province of Timnevelly produces a great quantity of indigo. Bengal produces, on an average, about nine millions of pounds annually. The sum which Europe annually pays for indigo is estimated at eight or ten millions of pounds sterling.

Indigo is, however, obtained from plants of other genera, particularly from _Wrightia tinctoria_ (natural order _Apocynaceae_), East Indies; _Baptisia tinctoria_ (natural order _Leguminosae_), North America, which yields indigo of a pale colour and very inferior quality; _Tephrosia tinctoria_ (natural order _Leguminosae_), Malabar; and _T. Apollinea_, Egypt and Nubia; _Marsdenia tinctoria_ (natural order _Apocynaceae_), in Sylhet; and _Podognecom tinctoria_ and _P. Chinense_ (natural order _Polygonaceae_), China and Japan._ Wrightia tinctoria_ is a large shrub, indigenous to great part of India and to Ceylon, yielding indigo of the poorest quality, and is remand- ed by Dr Boxburgh for cultivation, as less dependent than the common indigo plants on rain and irrigation. It grows very freely, and throws out shoots rapidly on their being cut away. —In times when East Indian indigo was not known, or was brought to Europe only in small quantity, the same dyestuff was obtained from _Woold_ (q.v.). —A coarse kind of indigo, called _Koad Indigo_, was also at one time made in North America from the young shoots of _Amorpha carolins_.

The Manufacture and Applications of Indigo.—The indigo plant, in its general appearance, is not unlike the laverne of our fields. The seed is sown in the autumn, and, when the capsules are fully filled, the case or pod is almost entirely shed, as if by the action of the sun, but this is more easily and more quickly accomplished in the case of the indigo plant. The fruits are then cut off, and are then cut down, but soon shoot up again, and give two or three more crops in the same year. Formerly, indigo was carefully dried after being cut, and even fire-heat was sometimes used for the purpose, but now—at least in India—the practice is abandoned, and it is found in every respect better to use the plant whilst fresh and green. The first process is to place in a shallow wooden vat as much as will loosely cover the bottom of it; water is then let in about 4 inches deep, and heavy wooden frames are put on the top, to prevent them from floating. Being left in this state for from fifteen to twenty hours, fermentation is set up, and much gas disengaged, the water becoming a light-green colour. The green liquor is then run off into the second vat, which is placed below the level of the first, in which, whilst the fermentation process is being repeated upon a fresh supply of vat, it is violently agitated by being beaten with poles: this causes the green, as it is called, to separate, and the green matter suspended in the liquor becomes blue and granular; and this change is promoted by the addition of a little lime-water from time to time. When this operation is sufficiently advanced, the contents of the vat are allowed to settle, and in a short time the now intensely blue granular matter has sunk to the bottom, leaving the supernatant liquor almost clear as water; this is then run off nearly to the bottom, and the sediment is then run into the third vat, which is below the level of the second: here it awaits several other additions from successive operations; and a sufficient quantity being accumulated in the third vat, it is suffixed to subside, and when thoroughly settled, the clear liquid is drawn off, and the granular matter is then removed, and filled into coarse bags, which are hung up to drain. When sufficiently drained, the blue paste is filled into very small boxes about three inches square, and set to dry in the sun, which soon renders it fit for packing.

This dye is, without doubt, the oldest in use; the Greeks and Romans obtained a knowledge of its use from India, where its employment has been very general for a great length of time. Much obscurity involves indigo and its early use, in consequence of the variation in its name; for instance, the Tamoogs of the Northwest frontier of India call it _Neloam_, and _Nelom_, in Sanscrit, the plant is _Vishthanpouna_ and the dye _Nili_ and _Nilfi_, whence the _Aoil_ of the Portuguese. The Malays call the dye _Taroom_, and the Arabs, _Ned_.

Commences:—In the making, indigo may be said to be the produce of India and Central America, as these are the only localities which supply the recognised form of the article. In India, the chief seat of the indigo manufacture is Bengal. France is the second district. The total quantity received in Great Britain in 1861 was nearly 80,000 cwt.—a vast quantity, when it is borne in mind with what difficulty it is cultivated and manufactured. When pure, indigo has a rich, dark-blue colour, almost purple: it is in small cubes or parts of cubes, and its fracture shows a tendency to break up into square pieces, and indicates cracks in its substance, often filled up with a film of whitish efflorescence, which, when removed, gives the liquor a very pleasing taste. It has neither taste nor smell, and its specific gravity is about 1.50; if rubbed with any hard substance, it gives a streak with a bright coppery lustre. The varieties recognised in commerce are 3d., 2d., 1st, and Saffron. The 3d. amalgamates easily, and the large scale on which it is made in that district, is the best; and its various gradations of quality, ten in number, varying from 9s. to 5s. per pound, are always kept distinct. In other sorts, they are usually much mixed. 2d. Madras and Kurpali; 3d. Oude, 4th. Manilla; 5th. Java; and 6th. South American. The last is packed in boxes or cases of dried ox-skin, and its qualities are distinguished as follows: 1st, Flore; 2d, Sobres; and 3d, Cortes; all the others are in wooden chests, containing about 250 lbs. each.

Few materials are of greater importance to the dyer than indigo, and none require the exercise of more care in its application. It is added to water, it requires the action of other solvents to render it capable of penetrating the fibres of the materials to be dyed. The method generally employed is the following: The indigo is broken into small lumps, and these are soaked in hot water, and left for at least 48 hours, in order that the mordure may soak through and soften them; after which they are put into the indigo-mill, which is a leav- ing machine, consisting of a vessel in which a roller is made to work by machinery, so as to rub down the indigo, mixed with plenty of water, to a very
INDO-GERMANIC LANGUAGES—INDORSED.

fine paste. This is a tedious operation; therefore, in large establishments, there are usually vacuum mills in the grinding-room. When sufficiently ground, the paste is removed to the dyeing-vat, where to one part of indigo is added one part of lime and three-fourths of sulphate of copper; these are well mixed with sufficient water, and in this state, the indigo then proceeds to dye either cotton, linen, or silk goods. See DYEING. After being dyed, the goods are dipped into a bath of diluted sulphuric or hydrochloric acid, which gives brightness and purity to the colour; they are then rinsed by washing in a stream of pure water, and drying.

Green indigo, called Lo-ko by the Chinese, is a substance resembling indigo, which is obtained from a tree called Hom-bi; it is highly valued by the Chinese artists as a pigment, and also gives a beautiful permanent green colour to cotton and silk cloths; it is, however, so costly, that it never can, unless differently prepared, be used as a dyeing material.

The fact that the Chinese dye cotton cloths with it, is accounted for by the nature of the process of preparing the lo-ko, which is this: A well-macerated decoction of the bark of the hom-bi tree is largely diluted with water mixed with a little lime; pieces of cotton cloth are then dipped into the vat, and taken out and exposed to the sun, which changes them to a bright green; they are then placed in perfectly clean water, and agitated until the water has removed all the free colouring matter; this water is then thrown into the small sediment ladle and the left is the lo-ko. It is the cotton cloths thus used that are sold as green-dyed goods. It is said that a similar dye stuff is obtained from another tree called Pu-bi, and although this, as made by the natives, is much too costly to use in European dyeing, yet probably, if better means of obtaining it can be pointed out, it may become an important article of commerce.

Chemistry of Indigo.—The plants which yield indigo present no indication, when growing, that they contain any chromogen, or matter capable of yielding pigment, nor is it definitely known in what form the indigo exists in the vegetable tissues.

The indigo of commerce is by no means a homogeneous body. Its essential and most important constituent is Indigothin or Indigo Blue, but it likewise contains Indigo Brown, Indigo Red, and other ingredients.

Indigo Blue, or Indigothin (C₃₂H₂₇NO₁₈), is obtained from commercial indigo by extracting the ingredients with which it is mixed by acetic acid, alkalies, and boiling alcohol. It occurs either as a dark-blue amorphous powder, or in purple crystalline scales, with a metallic lustre. It is devoid of smell and taste, and is insoluble in water, alcohol, ether, dilute acids, and alkalies. When carefully heated, it may be sublimed without decomposition. Among the products of its destructive distillation are hydrocyanate and carbonate of ammonia, aniline, &c. Indigo blue dissolves without any evolution of gas in strong sulphuric acid, forming a blue solution of sulphanilic acid, which is extensively used for dyeing cloths under the name of Saxony Blue.

Under the action of reducing agents, such as alkaline fluids containing sulphate of iron, or a mixture of grape-sugar, alcohol, and strong soda lye, indigo blue becomes converted into Indigo White or Reduced Indigo, which forms a yellow solution in alkaline fluids, but which, on free exposure to the air, absorbs oxygen, and is reconverted into indigo blue. Indeed, this is the best method of obtaining the latter in a state of purity as commercial indigo, of which it should form about 50 per cent.

Indigo blue occurs in small quantity in the urine of man, the horse, and the cow, and occasionally in the milk of the cow, when these fluids have been exposed for some time to the action of the air; but Schuckn obtained it from the urine in so many cases (in the urine of 39 persons out of 40), that Indican (or the chromogen yielding indigo blue) must be regarded as a normal urinary product. M. Schuckn's paper in The Memoirs of the Literary and Philosophical Society of Manchester, 1857, vol. xiv., or Day's Chemistry in its Relations to Physiology and Medicine, 1860, pp. 310—312.

Indigo White or Reduced Indigo, in a state of purity, occurs in white flakes, which are devoid of taste or smell, are perfectly neutral, and are insoluble in water, but dissolve in alcohol, ether, and alkaline solutions. Its chromogen composition is represented by the formula C₁₂H₁₇NO₁₈, and as it only differs from indigo blue, C₃₂H₂₇NO₁₈, in containing one more equivalent of H, it may be considered as the hydride of the latter. If yarn or woven goods be immersed in an alkaline solution of this substance till they are thoroughly saturated, and are then exposed to the air, indigo blue is formed within the fibres of the tissue. The blue dye thus obtained is very intense and permanent. From its insolubility in water and property of becoming blue on exposure to the air, indigo white is a sensitive test for the presence of free oxygen.

Many compounds of great chemical interest have been derived from indigo blue. It was from indigo that aniline (now so largely employed in the production of the pigments known as mauve and magenta) was first obtained.

INDO-GERMANIC LANGUAGES. See Aryan Languages.

INDORE, a Mahatta principality of Hindustan, consists of several detached tracts, some of them lying very remote from each other. With an aggregate area of 8318 square miles, and an aggregate population of about 800,000, the territory, as a whole, is traversed from east to west by the Nerbudda, and also by the Vindhyas Mountain, their lowest point within its limits being 2200 feet above the sea. The revenue is nearly a quarter of a million sterling; and the armed force amounts to about 20,000 men. Besides the capital, the chief towns are Rampura, Mehadoor, Dhi, Pitaul, Mundhia, Bhanpura, and Mhow. It is peculiarly the country of the Bheels, one of the wildest and most savage of the aboriginal tribes of India. The country, including all between its extremities, stretches in N. lat. from 21° 18' to 24° 46', and in E. long. from 74° 39' to 76° 27'. The climate is sultry, the thermometer ranging from 60° to 90° F. in the shade.

INDORE, the capital of the principality of the same name, is situated in 22° 42' N., and long. 75° 50' E., on the left bank of the Kuthi. It stands about 2000 feet above the level of the sea, and is estimated to contain 15,000 inhabitants. This place, mean and insignificant enough in itself, acquired considerable notoriety in connection with the grand revolt of 1857. Though Holkar, the rajah, remained faithful to the British government, yet his troops mutinied on July 24, 1857. The rajah, having been captured by the mutineers, was sentenced to death, and person of his own palace, and butchering many Europeans, men, women, and children, in cold blood.

1. is of modern erection, having been founded in 1767; and its original name, now Jemmah, still exists on the opposite bank of the river.

INDORSED, ENDORSED, ADDRESSED. Terms applied to Heraldry to two animals placed back to back. Two keys, two wings, &c., may also be indorsed, and a pelican is always drawn with his wings indorsed.
The term Inorsement is used to denote the writing of the name of the holder on the back of a bill of exchange or promissory note, on transferring or assigning it to another. Signing the name 'A. B. alone is a blank Inorsement; and if the name is miswritten, it is a special indorsement. The usual form is, 'Pay C. D. or order, (Signed) A. B.' In Scotland, it is, 'Pay the content to C. D. or order. (Signed) A. B.' When personal likenesses are to be avoided, the words 'without recourse' are added.

The word Inorsement is also frequently used in English law, to denote any matters written or inforced on the back of a bill of exchange, bills of lading, or other documents, as indorsements on declarations, or written on the back of a note, and to denote anything so written or attached.

In the Sanscrit id, which probably meant 'to see, to discover,' hence literally, 'he who sees or discovers,' soi, the doings of the world is the name of one of those Hindu deities that were worshipped more especially in the Vedic period of the Hindu religion, but enjoyed a great legendary popularity also in the Epic and Puranik periods. See India, sect. Religion. In that class of Rig-Veda hymns which has reason to look upon as the oldest in the entire Vedic poetry, the character of I. is that of a mighty ruler of the bright firmament, and his principal fest is that of conquering the demon Victory, a symbolical personification of the cloud which obstructs the clearness of the sky, and which, by obstructing the pouring rain from the earth. In his battles with Victory, he is therefore described as 'opening the receptacles of the waters,' as 'clearing the cloud' with his 'far-whirling thunderbolts;' as 'casting the waters down to earth,' and 'restoring the clear blue sky.' He, in consequence, is 'the upholder of heaven, earth, and firmament,' and the god 'who has engendered the sun and the dawn.' And since the atmospheric phenomena personified in this conception are ever and ever recurring, he is 'unbecoming' and 'ever youthful.' All the wonderful deeds of I., however, are performed by him merely for the benefit of the good, which in the language of the Veda means the pious men who worship him in their songs, and inigrate him with the offerings of the juice of the soma plant. See India, sect. Religion. He is therefore the 'lord of the virtuous,' and the 'discomfitter of those who neglect religious rites.' Many other epithets, which we cannot enumerate, are used by the Vedic poets to illustrate the same conception. It is on account of the paramount influence which the deeds of I. exercise on the material happiness of man, that this deity occupies a foremost rank in the Vedic worship, and that a greater number of invocations are addressed to him than to any other of the gods. But to understand the gradual expansion of his mystical character, and his ultimate degradation to an inferior position in the Hindu pantheon of a later period, it is necessary to bear in mind that, however much the Vedic poets call I. the protector of the pious and virtuous, he is in their songs essentially a warlike god, and gradually endowed by imagination, not only with the qualities of a mighty, but also of a self-willful king.

The legends which represent him in this light seem, it is true, to belong to a later class of the Rig-Veda hymns, but they shew that the original conception of I. excluded from his nature those ethical attributes which in time changed the pantheon of elementary gods into one of a different stamp. Whether the idea of an incarnation of the deity, which, at the Epic and Puranik periods, played so important a part in the history of Vishnu, did not exercise its influence as early as the composition of some of the Vedic hymns in honour of I., may at least be matter of doubt. He is, for instance, frequently invoked as the destroyer of cities—of seven, of ninety-nine, even of a hundred cities—and he is not only repeatedly called the slayer of the hostile tribes which surrounded the Aryan Hindus, but some of the chiefs slain by him are enumerated by name. The commentators, of course, turn these 'robbers' and their 'chiefs' into demons, and their cities into celestial abodes; but as it is improbable that all these names should be nothing but personifications of clouds destroyed by the thunderbolts, it is, in this, at least, questionable whether events in the early history of India may not have been associated with the deeds of I. himself, in the manner as, at the Epic period, mortal heroes were looked upon as incarnations of Vishnu, and mortal acts of the Puranik periods, where ethical conceptions of the divine powers prevail over ideas based on elementary impressions. I. ceases to enjoy the worship he had shared in this respect, the character of I., which was chiefly upheld by the poets, who, in their turn, however, work it out in the most fantastical detail. Of the eight guardians of the world, he is then the one who presides over the east, and he is still the god who sends rain and yields the thunderbolts; but poetry is more engrossed by the beauty of his paradise, Suvarch, the happy abode of the inferior gods, and of those pious men who attain it after death, in consequence of having during life, properly discharged their religious duties; by the charms of his heavenly nympha, the Aparatana, who now and then descend to earth, to disturb the equanimity of astute penitents; by the musical performances of the demons, the Gandhara, by the splendour of his capital, Amanasa, by the fabulous beauty of his garden, Neandana, &c. A remarkable trait in this legendary life of I. is the series of his conflicts with Krishna, an incarnation of Vishnu, which end, however, in his becoming reconciled to the more important god. As the god who is emphatically called the god of the hundred sacrifices (Satukratu), I. is jealous of every mortal who may have the presumption of aiming at the accomplishment of that number of sacrifices, for the accomplishment of such an intention would raise the sacrifice to a rank equal to that which he occupies. He is therefore ever on hand to disturb sacrificial acts which may expose him to the danger of having his power shared by another Indra. According to the Puranik, the reign of this god I., who is frequently also called Sakra, or the mighty, does not last longer than the first Mansangantra, or mundane epoch. After each successive destruction of the world, a new I. was created, together with other gods, saints, and mortal beings. Thus, the L. of the second Mansangantra is Viprunashta; of the third, Sutundrasana; of the fourth, Sivi; of the fifth, Vida; of the sixth, Vida, and his existence in the present age is Parvadura. When represented in works of art, I. is generally seen riding on his elephant; and where he is painted, he is covered with eyes.

Indrant, a name of the wife of the Hindu god Indra (q. v.).

Indre, a central department of France, formed out of the western portion of the old province of Berry, lies immediately south of the department of Loir-et-Cher. Area, 267 square miles; of which 1550 are in tillage, and 321 in pasture. Pop. 270,054. The department is well watered, the chief rivers being the Indre, the Creuse, and its tributary the
INDRE—INDUCTION.

Aslin. The surface is for the most part flat, and the land is generally fertile, producing large crops of wheat and barley. The two principal resources of the district are its flocks of sheep and its lands. The climate, except in the district of La Brenne, is mild and healthy. The principal manufactures are woollen and linen cloths, harness, knitwear, paper, and porcelain. Iron mines are worked in the district. The department is divided into four arrondissements—Châteauroux, Le Blanc, Issoudun, and La Châtre. The capital is Châteauroux.

INDRE, a river of France, rises on the northern border of the department of Creuse, flows north-west through the departments of Indre and Indre-et-Loire, and joins the Loire 17 miles below Tours, after a course of 136 miles, for the last 40 of which it is navigable.

INDRE-ET-LOIRE, an inland department of France, formed out of the ancient province of Touraine, lies north-west of the department of Indre, Area, 3,240 square miles, of which more than one-half is arable; pop. 323,572. The department is watered by the Loire, the chief river, and by its tributaries, the Cher, the Indre, and the Vienne, all of them navigable. The Loire, with its affluents, which otherwise would be frequent and disastrous, is banked in by dykes throughout its course in this department. See LOIRE. The soil is arable, wooded, and the chief manufactures are iron, woolen cloth, silk, and leather. The department is divided into the three arrondissements of Tours, Chinon, and Loches; capital, Tours.

INDUCIBLE LEGAL LIES, in Scotch law, means the number of days which a defender has to answer a summons. The term is not used in England, the phrase being "so many days to answer, to plead, &c."

INDUCTION of clergyman, a term used in England and Ireland to denote the investing or giving possession of benefice to a clergyman, or, in Scotland, to be made by a mandate from the bishop to the archdeacon or corresponding official to make the induction. The indutor takes the clergyman by the hand, and lays it on the ringer, or latch, of the church-door, or puts him into the church, and generally the church bell is tolled, to give notice to the parishioners. In Scotland, the prebendary indutes the minister.

INDUCTION, the name for one of the great processes of scientific discovery and proof. It has been seen under Generalization, that when we rise from particular facts to generalities, the result may take one of two forms—a general notion, or a general proposition. "circle is 4 a notion; circle is the line that encloses the largest space," is a proposition. The mode of arriving at such general affirmations, truths, or laws, is what is called induction. The strict meaning of the term is the operation of discovering and proving general propositions: "circle is a notion; circle is the line that encloses the largest space," is a proposition. While deduction, on the other hand, is the method of applying general propositions once discovered to particular cases, considered to be included within the scope of the generalization. By induction, we arrive at a law that heat expands bodies; by deduction, we apply it to explain why a clock is slower in summer than in winter, owing to the changes of the length of the pendulum.

Induction is the only process of real inference in other words, by it we proceed from the known to the unknown; or from a limited range of facts, we affirm what will hold in an unlimited range. All things that we do not know by actual trial or ocular demonstration, are inferred by an inductive operation. Deduction is not real inference in this sense, since the general proposition already covers the case that we apply it to; in a proper deduction, the conclusion is more-limited than the premises. By the inductive method, we obtain a result much larger than the premises; we adventure into the sphere of the unknown, and pronounce upon what we have not yet seen. This operation necessarily implies a certain hazard; and it may be easily supposed that there are precautions requisite in working it. Nothing is more common than the making of bad inductions; and accordingly it is now considered a part of logic to lay down the rules for the right performance of this great operation.

A preliminary question arises—How can we ever be entitled to dogmatise beyond the sphere of our actual experience? to conclude, for instance, that five miles below the surface of the earth, there is heat enough to make water boil? The answer to this question supplies us with what is called the ground of induction, which is the fact, now established by the experience of centuries, that nature is uniform. What has happened once, will happen again, provided the same circumstances and conditions exist. All things are exactly repeated. At a former period of the world's history, there might have been doubts on this matter, and opinions were actually held that implied a want of perfect uniformity, but now those doubts are dispelled, except perhaps, with reference to a single questionviz, the freedom of the will (see Free Will). Accordingly, the problem to be solved is to ascertain what is the order of nature in the instances accessible to our observation.

The uniformity of nature is a conception formed from many separate uniformities. In other words, there are different departments or classes of phenomena, each determined by separate laws. Thus, we have mathematical, physical, chemical, physiological laws, the statement of which severally constitutes the subject-matter of each of these sciences. Now, a distinction is observable, which is of some importance as regards the method of inductive investigation. Some of the phenomena thus conjoined under uniform principles are properties simultaneously existing, as the properties of mathematical figures; others are successions, and affirm order in time, the most important of all which is that peculiar succession denominated cause and effect. See divers. The problem of inductive inquiry is in a great measure occupied with this one department, although there are also inductions respecting contemporaneous or conjoined properties. Natural history is in part made up of affirmations of simultaneous properties, as, for example, the anatomical structure of animals, and in part of affirmations of cause and effect, as in all the operations that sustain life, and determine reproduction, growth, and death.

Respecting the whole of the phenomena implied under Causation, the principle of nature's uniformity is embodied in one great and comprehensive statement, called the law of causation; the import of which is, that whatever begins to exist is either preceded by something else, to which it invariably succeeds. Events do not arise of themselves, or out of nothing; and although there is such a thing as Plurality of Causes, everything that arises and proceeds by some other thing as a cause, and always follows when that cause occurs; there being supposed no counteracting agency. The aim of the scientific inquirer, then, is to single out from the mass of circumstances that have occurred, and preceded any event, some one or more that invariably
INDUCTION.

precede the occurrence of that event, which being found, are thenceforth known as its cause. This has to be accomplished by a process technically called elimination, by which is understood a series of operations intended to separate everything that is indifferent to the production of the phenomenon, until we arrive at some one thing or more that cannot be removed without making the effect to cease.

Mr John Stuart Mill, in his Logic, has illustrated in detail the methods to be adopted for making sure that one has singled out the true causative circumstance from among the many that may precede a given effect. They resolve themselves mainly into two. 'One is, by comparing together different instances in which the phenomenon occurs. The other is, by comparing instances in which the phenomenon does occur, with instances in other respects similar in which it does not. These two methods may be respectively denominated the Method of Agreement, and the Method of Difference.'

The Method of Agreement supposes that we make it a study to vary the circumstances under which the supposed phenomenon is produced. Either by observation of cases presented in nature, or by artificially contriving new cases, whether in nature, by means of observation, we do our utmost to obtain the effect in a great many different connections, whereby we ascertain what things are indifferent to it. Whatever circumstance can be excluded, the phenomenon still happening, or can be absent. Notwithstanding its presence, is not connected with it in the way of causation. The accidental or indifferent circumstances being thus eliminated, if only one remains, that is the cause; if the elimination does not go completely, but leaves things for four circumstances or agencies, we can only say that the cause is among them. Mr Mill enunciates the Method of Agreement in a formal canon, or rule of induction, to the following effect: If two or more instances of the phenomenon under investigation have one circumstance in common, the circumstance in which alone all the instances agree is the cause (or effect) of the given phenomenon.

If we could always obtain the requisite variety of circumstances for the exclusion of all indifferent adjuncts, this method would fully answer the ends of inductive inquiry. But this is not always to be had, and even when practicable, the operation is often very lengthy. When the other method (difference) can be applied, the desired end is reached by a shorter route. If, instead of excluding the indifferent agencies one by one, we can contrive an experiment, or make an observation, that excludes one agency or circumstance, followed by the cessation of the effect, we conclude at once that what has thus been left out is the cause, or an essential condition or part of the cause. Whenever we are so fortunate as to light upon two instances suited to this method, we establish causation at once and beyond all question. The experimentum crucis of Bacon was something of this nature; only it supposed that a question lay between two alternative or competing agencies, which had experiment had been hit upon for deciding such an experiment behoved to be one of Difference. This method is embodied in the following canon: If an instance in which the phenomenon under investigation occurs, and an instance in which it does not occur, have every circumstance, except one, in common, that one occurring only in the former, the circumstance in which alone the two instances differ is the effect, or cause, or a necessary part of the cause, of the phenomenon. This method also has two leading methods, but there are certain cases met by a procedure somewhat different. Sometimes we have a phenomenon made up of causes partly known and partly unknown. It is then possible to subduct the effects due to the known causes, and what remains will be attributed to the remaining agencies. This is expressed by Mr Mill in the following rule or canon: Subduct from any phenomenon such part as is known by previous investigation to be the effect of certain circumstances, and the residue of the phenomenon is the effect of the remaining antecedents. The more our knowledge is extended, the more able are we to proceed upon this method, termed the Method of Residues. 'It is by this process, in fact,' says Sir John Herschel, 'that science in its present advanced state is chiefly promoted.'

There remains a class of laws wherein the application of any of those three methods is rendered impracticable, from the circumstance that in their case is irremovable and indestructible, so that we cannot obtain any cases where it is entirely absent. Such an agent is heat, which can never be entirely separated from any body, so as to ascertain, by comparing cases of its presence with those of its absence, what effects are due to it. So we can never get out of the sphere of the earth's attraction. The difficulty hence arising is surmounted by one or other of two methods, one determining whether there be a corresponding variation in the degree of the effect. Thus, we infer that heat is the cause of the expansion of bodies, and that its total absence would lead to their maximum condensation and consolidation, by which the effects of any additions or subtractions of a body's temperature. Solids, liquids, and gases (with certain limited and special exceptions) are found expanding steadily as they are heated, and contracting as they are cooled; and this is to us a sufficient justification in considering that the law in question holds good. This process is termed by Mr Mill the Method of Concomitant Variations, and is expressed by him in the following terms: Whatever phenomenon varies in any manner, when another phenomenon varies in some particular manner, is either a cause or an effect of that phenomenon, or is connected with it through some fact of causation.

There are many problems growing out of the applications of induction to the great variety of natural phenomena, the main principles being nevertheless the same. An important extension of the means of scientific discovery and proof arises from the use of those phenomena as evidence to be considered and concluded in the operation of one or more of such laws. Thus, the great induction of universal gravity was applied deductively to explain a great many facts besides those that enabled the induction to be made. Not merely the motions of the planets about the sun, and the satellites about the planets, but the remote and previously unexplained phenomena of the tides, the precession of the equinoxes, &c., were found to be inferences from the general principle. This mode of determining causes is called the Deductive Method. When several agents unite in a compound effect, there is required a process of calculation to find from the effects of the causes acting separately the combined effect due to their concurrent action, as when the path of a projectile is deduced from the laws of gravity and of projectile force. It is the deductive stage of science that enables us to bring calculation to be brought into play with such remarkable success as is seen in astronomy, mechanics, &c. See DEDUCTION.

The circumstance that phenomena may result from a combination of causes, leads to the discussion between ultimate laws and derivative coordinate laws. Thus, gravity is an ultimate law; the movement of the planets in ellipses is but a subordinate
INDUCTION—INDUCTION OF ELECTRIC CURRENTS.

law. These inferior laws may be perfectly true within their own limits, but not necessarily beyond certain limits, of time, place, and circumstance. A different adjustment of the two forces that determine a planet's motion, would cause a circular or a parabolic orbit; and therefore it is, that when phenomena result from a combination of ultimate laws acting under a certain arrangement, they are not to be generalised beyond the sphere where that arrangement holds. These inferior laws are sometimes mere inductions that have not been reduced into their constituent laws, and thus they go under the name of 'Empirical Laws.' Thus, in the hands of Kepler, the elliptic orbit of the planets was only an empirical generalisation, ascertained by the Method of Agreement; Newton converted it into the first so-called induction of all the results from the more general laws of gravity, &c. The earlier stages of induction present us with many of those empirical laws; in some subjects—as physiology, medicine, &c.—the greater number of inductions are of a similar kind. Even when the disease is especially an example of this: hardly any medicine can have its efficacy traced to ultimate laws of the human system. Hence the uncertainty attending the indication of medicaments and drugs, and also the want of success that often attends them in circumstances where we think they ought to succeed.

Induction applies to other laws than those of causation—namely, to uniformities of co-existence. For the illustration of these, as well as the other parts of induction, see Mill's Logic, book iv.

INDUCTION OF ELECTRIC CURRENTS.

The discovery of the power of electric currents to induce currents in neighbouring conducting circuits is due to Faraday. His researches on the subject, named by him volta-electric induction, were published in the Philosophical Transactions (1831—1832). Henry (1832) observed that when contact was broken in a long galvanic circuit a bright spark occurred, which did not occur when the circuit was short. This was shewn by Faraday (1834) to be due to the extra current produced by the various parts of the circuit in each other. Buchhoffer and Recknagel (1837) showed the superior action, in induction apparatus, of a bundle of iron wires to that of a solid bar of iron. Henry (1841) studied the inductive action of induced currents of different orders. De la Rive designed, in 1843, an electrochemical condenser, consisting of a primary coil, which, by means of the extra current, could enable a single galvanic cell to decompose water. The same decomposition, however, had been effected by Wright in 1840. Ruhmkorff constructed (1850 or 1851) a form of inductive apparatus, of which was chiefly attained by the proper insulation of the secondary coil. Fizean (1853) increased immensely the power of the coil, by providing it with a condenser. Of late years, coils of great power have been constructed, rivalling, if not exceeding, the most powerful electric machines in length and power of spark.

The fundamental law of current induction may be thus stated: the long copper wires, in (fig. 1) and in (fig. 2), are fixed so as to be parallel and close to each other. The extremities of the one, in, are in connection with the poles of a galvanic battery, G, and those of the other, in, with the binding-screws of a galvanometer, G. The instant the circuit of the battery is completed, and the current sent along in, a current in the opposite direction is induced in the wire in, which is shown by the deflection of the needle of the galvanometer. The induced current is only momentary, for though the current continues to circulate in in, the needle soon falls back to its original position of rest, and the wire in gives free passage to other currents, and appears to be in no way affected. If, now, when the needle is at rest, the battery circuit be broken, and the current in in stopped, another momentary current is induced by the galvanometer needle, but in this case in the same direction as the inducing current. The inducing wire and current are called primary, and are so distinguished from the induced wire and current, which are termed secondary. The magnetic excitation of the wire while thus under induction has been described by Faraday as electrotonic. An electric throb, so to speak, marks the setting in of this state, and another its vanishing; the former in the opposite direction to that of the inducing current, and the latter in the same direction. If the primary wire, in, be movable, so that it can be suddenly brought near to, and withdrawn from, the secondary, in, while the battery current passes steadily, currents are induced as in the former case, the approach of the wire being marked by an inverse current, and its withdrawal by a direct one. As long, however, as the primary wire remains in any one position, all evidence of electricity in the secondary wire disappears; but if in this position the strength of the primary current should be increased or diminished, momentary currents in the secondary wire would again mark the changes in the primary, the increase causing an inverse, and the decrease a direct current. Hence we conclude, that a current which begins, a current which approaches, or a current which increases in strength, induces an inverse momentary current in a neighbouring conducting circuit, and that a current which stops, a current which retires, or a current which decreases in strength, induces a direct momentary current in a neighbouring circuit. For inverse, the word negative, and for direct, the word positive, are frequently employed in reference to induced currents.

In experiments like the above, it is much more convenient to wind the primary and secondary wires side by side round a bobbin, so as to form a coil, as in fig. 2. The wires are insulated from each other by a covering of wool or silk. Not only does such a disposition admit of very long wires being used, but it also disposes the wires employed to greater advantage, for each single turn of the primary wire acts not only on the corresponding turn of the secondary wire, but on all the turns near it. The inductive effect of such a coil is much greater than that which would be obtained by the same extent of wires running side by side in a straight or crooked line. It is not even necessary that the two wires
be wound round together, each may be wound on
a separate bobbin, and the one placed inside the
other, as in fig. 3. The primary coil, P, here
represented, is made of wire \( \frac{1}{4} \)th of an inch
diameter, covered with wool; and the secondary
coil, S, of silk-covered wire, about \( \frac{1}{4} \)th of an
inch, and much longer than the primary wire.
With two such coils, the illustration of the pre-
ceding principles of induction can be conveniently
given. If the primary coil be placed in the circuit
of a galvanic cell, by two loose and flexible
wires, so as to allow of its easy motion, and if the
terminal binding-screws of the secondary coil be
placed in connection with a galvanometer, when P
is inserted into S, a momentary inverse current
is indicated, and when it is removed, a momentary
direct current; or if, when P remains in S, the
strength of the primary current be altered, the needle
announces the induction of currents according to
the principles stated above. In order, however, to
obtain the greatest effect from the secondary coil S,
it is necessary, whilst P remains within it, to have
some means of continuously completing and break-
ing the primary current. A contrivance for this
purpose is called a rheotom, or current-break. A
simple rheotom may be made of a common file, by
hobbling one wire from the battery against the end
of the file, and running the other along the teeth,
the current being stopped each time the wire leaves
a tooth. In this way, a rapid series of interruptions
is effected, each of which is attended by an inverse
and a direct current in the secondary wire. A break
of the same description, but more constant,
may be also made by causing a metal spring to
press against the teeth of a metal wheel, both
spring and wheel being connected with the battery.
As the wheel is turned by a handle, the spring
breaks the contact each time it slips from one tooth
to another. The most convenient form of break,
however, is one which is made self-acting by the
action of an electromagnet, which receives the
name of a magnetic hammer.

**Quantity and Tension of Induced Currents.**—Let us
place the coil P within S; let P, along with a self-
acting rheotom, be put in the circuit of a galvanic
cell, and let S be connected with a galvanometer.
The interruption in the primary current being
effected by the rheotom with great rapidity, the
induced inverse and direct currents are sent with
the corresponding rapidity through the coil of the
galvanometer. If this last be of a short and thick
wire, so as not to tax the tension of the current
transmitted, the induced currents will not deflect
the needle; or if they should happen, through the
unsteady motion of the break, to do so, it only
oscillates round its position of rest. This proves
that the quantity of electricity transmitted by the
induced inverse and direct currents is the same, for
they each exert the same influence on the needles.
But if the coil of the galvanometer consist of a
long fine wire, the needle is kept deviated in a
direction which argues the action of the direct
current. This leads us to conclude, that both
currents, though equal in quantity, are unequal in
tension. 

The difference of the tension of the two induced
currents is accounted for in this way: when a change
takes place in the primary current, the quantity
of the electricity induced by it in the secondary
wire will be the same whether the change occurs
quickly or slowly; the tension, however, is very
different. When the change takes place slowly, the
total quantity of electricity in circulation continues
to pass as slowly, and there is little in motion at one
time; but if the same occurs quickly, it is sent
with momentum, so to speak, and the quantity in
circulation at one time is as much greater, in com-
parison with the former case, as the time is shorter.
It is this quick dispatch of electricity which consti-
tutes that which is called the inverse current. It is
sent at some time before the primary current is fully
established, the inverse induced current is slow and
of low tension; but when the contact is broken, the
primary current ceases much more suddenly than it
began, and the direct induced current is increased
at the same time, and of high tension. This view of the matter is borne
out by experiment, for it is found, that whatever
favours the suddenness of the change of the primary
current, heightens the tension of the currents induced
by those changes. The break, from this circumstance,
forms an important element in the construction of
all induction apparatus.

The inductive power of the primary coil is
immensely increased by placing such objects as iron
rods or wires in the centre of it. The magnetism
which begins and ceases in these at each passage of
the current acts in conjunction with the inducing
force of the coil. The centre of the bobbin P (fig. 3)
is hollow, to receive a handle of this kind, and
the greater part of the inductive action is due to the
iron core, and the induced currents got with and
without it are not to be compared in point of energy.
A solid bar of soft iron may also be used, but
with much less advantage, for the inductive currents
which linger in it after the stoppage of the main
current, acting themselves inductively, impair the
suddenness with which the current disappears from
the primary wire and magnetism from the core.
The thin layer of oxide which forms on the rods
insulates them sufficiently from one another, and
prevents the formation of such currents. It is partly
for the same reason that metal tubes cannot be used
for blowing for either primary or secondary coils.
If such were used, closed circuits would be formed
in them, the reaction of which would prolong the
changes of the primary inducers, and consequently
impair the tension of the secondary current. Metal
bobbin P, fig. 3, is not connected with the coils,
had a longitudinal slit, which would make the
transverse section a broken ring and circuit.

The excitation of magnetism in the core is the
principal aim of the primary coil, and as a strong
current is essential to that object, it is made of thick
wire and of moderate length. In the secondary
coil, the tension of the induced current alone is
aimed at, and with this view it is made of as thin
wire as can be made, so as to admit \( \frac{1}{4} \) as many

---

**INDUCTION OF ELECTRIC CURRENTS.**
INDUCTION OF ELECTRIC CURRENTS.

The current in one conductor will induct a current in a neighboring circuit, but it also acts inductively on itself. The induced current is of the opposite direction to the original current, and is proportional to the number of turns in the coil, the length of the path of the induced current, and the intensity of the exciting current.

The total electro-motive force of the coil is the sum of the electromotive forces of all the turns in it, and is equal to the sum of the electromotive forces of all the loops formed by the turns.

The induced current acts like a battery, and may be used for various purposes, such as lighting a lamp, heating a wire, or starting a motor.

The induced current in a coil is proportional to the number of turns in the coil, and is given by the formula:

\[ I = N \frac{d\Phi}{dt} \]

where \( I \) is the induced current, \( N \) is the number of turns in the coil, \( \Phi \) is the linkage of the magnetic field with the coil, and \( \frac{d\Phi}{dt} \) is the rate of change of the linkage.

The induced current in a coil is proportional to the rate of change of the linkage of the magnetic field with the coil, and is given by the formula:

\[ I = N \frac{\Delta \Phi}{\Delta t} \]

where \( I \) is the induced current, \( N \) is the number of turns in the coil, \( \Delta \Phi \) is the change in the linkage of the magnetic field with the coil, and \( \Delta t \) is the time interval during which the change occurred.

The induced current in a coil is proportional to the rate of change of the linkage of the magnetic field with the coil, and is given by the formula:

\[ I = N \frac{\Delta \Phi}{\Delta t} \]

The induced current in a coil is proportional to the rate of change of the linkage of the magnetic field with the coil, and is given by the formula:

\[ I = N \frac{\Delta \Phi}{\Delta t} \]

The induced current in a coil is proportional to the rate of change of the linkage of the magnetic field with the coil, and is given by the formula:

\[ I = N \frac{\Delta \Phi}{\Delta t} \]

The induced current in a coil is proportional to the rate of change of the linkage of the magnetic field with the coil, and is given by the formula:

\[ I = N \frac{\Delta \Phi}{\Delta t} \]

The induced current in a coil is proportional to the rate of change of the linkage of the magnetic field with the coil, and is given by the formula:

\[ I = N \frac{\Delta \Phi}{\Delta t} \]

convolutions of which are in constant rotation. This hazy spark can be blown away by the breath, and separated from the white spark which cannot be so removed. As the rods are withdrawn from each other, it disappears, and when they stand above three inches apart, the spark resembles in every respect the forked single spark of the electric machine. When the points are withdrawn beyond striking distance, electric brushes still play between them, which become visible in a dark room. If the hand be brought near the rod connected with the figure E, sharp stinging sparks, two or three inches in length, are got. The rod connected with the inner end does not yield them so readily, and this is the source of the negative pole.

When a gold-leaf electroscope is brought near the leaves part energetically from each other; and when a spark is received by it from one of the rods, it remains permanently charged. When, however, the leaves are brought into direct contact with either of the rods, this action ceases, because the induced currents, inverse and direct, neutralise each other. When the knob touches, both currents affect the leaves equally; but when it is at some distance from a direct current enough to act. Each pole of the induction coil is the seat of two opposite electricities, alternating with each other, alike in quantity, but differing in tension, and this accounts for the resemblances and differences between the coil and machine electricities. When the poles are put in connection with the coatings of a Leyden jar, the sparks passing between the points are much more brilliant, and the sharp snap of the simple spark grows into a loud report. The Leyden jar effects a condensation of the electricity of each direct current, and each spark discharge takes place in shorter time, and consequently with greater intensity. The condensed spark phenomenon is a prototype of the spark with great facility, but it is of very low heating power. The uncondensed spark, more particularly the hazy spark, got when the poles are near each other, kindles paper, gunpowder, coal-gas, and other combustibles with readiness and certainty, brous &c. in this property of its spark that the induction coil is of so great use in mining operations. The two ends of the wires coming from the coil are fixed near each other without touching, and are imbued in a charge of gunpowder at a safe distance from the operator. The wires are insulated by gutta-percha. and when the induced current is sent through them, sparks pass through the gunpowder between the ends of the wires, and set fire to it. When several charges have to be ignited simultaneously, the spark of the coil-machine is considered much more reliable than the action of a powerful galvanic battery in heating thin wires connecting the ends of the battery-wires. See Galvanism. The power of the direct induced current of even large induction coils to deflect the magnetic needle, and to effect chemical decomposition, is very insignificant. This shows that it is very much inferior to the inducing current in quantity; however much it may be superior in tension. The physiological effect, on the other hand, is tremendous, and the experimenter must take care not to allow any part of his body to form the medium of communication between the poles, as the shock so got might be dangerous, if not fatal.

When the induced current is made to pass through nearly vacuum spaces, a very splendid effect is produced. The Electric Egg (fig. 5) is employed to display this. It consists of a glass vessel in the shape of an egg, with an open neck above, and another below. Brass fittings are attached to these. The lower opening is fitted with a stop-cock, and can be screwed to the plate of an air-pump. A brass rod and ball rise a short way into the egg. The fittings above are intended to allow of a rod ending in a ball passing up and down air-tight. It then the spark of a powerful gun is made to be conveniently set at different distances. When the egg is exhausted, and the wires from the coil are attached, the one above the ball can be instantly thrown to any height. The luminous glow extends between the balls, which is wide in the middle, and contracts at either extremity. When the exhaustion has reached one-twelfth of an inch, as shown by the gauge of the air-pump, the black bands are seen to lie horizontally in the light, so as to wear the appearance of stratification, as shown in the figure. These occur more readily when a drop or two of turpentine, alcohol, or ether have been placed on the egg. The cause of the stratification is as yet a matter of speculation. The ball which forms the negative pole is enveloped in a covering of blue light. The glow, which is of a beautiful mauve tint, appears to proceed from the positive ball, and reaches nearly to the negative ball, from which it is separated by a well marked non-luminous space. By means of the commutator, these appearances at the balls can be instantly transposed. Serving the same purpose as the electric egg, there is a great variety of vacuum tubes hermetically sealed and ready for use at any time. These have been first filled with particular gases, and then exhausted, and they exhibit lights of various tints, according to the gas contained by them.

INDULGENCE, in Roman Catholic theology, means a remission, by church authority, to a repentant sinner, of the temporal punishment which, in the doctrine of the church, remains due after the sin and its eternal punishment have been remitted. A doctrine which has been the subject of so much angry controversy, and which may be regarded as the chief among the proximate causes of the Reformers' severe censure, preserves very careful consideration. We must confine ourselves, however, to a brief authentic explanation of the doctrine such as it is held by Roman Catholics, together with a history of the practice in the various ages of the church.

By the discipline of the first centuries, a severe course of penitential observance was exacted of all who fell into any grievous crime, especially apostasy, murder, and adultery, such sinners being excluded from church communion for various periods, in some cases even till the hour of death. These penitential observances, which Protestants regard as purely disciplinary, were designed, according to the Catholic view, as an expiation, on the part of the penitent, for the temporal punishment which, after sin and the eternal punishment due to it have been remitted by God, still remains to be undergone; and some of the most acriominous of the early controversies, the Montanist and the Novatian, arose as to the power of the church to relax these penitentials, or so far to relax and to admit grievous sinners to communion. These ancient relaxations (of which they regard that referred to in 1 Cor. v. 5 and in 2 Cor. ii. 10 as a type) are considered by Catholics as examples of the modern indulgence; and the practice which grew up in the 3d and 4th centuries, and which even then
was carried to great extremes, of granting such relaxations on the recommendation of martyrs or confessors, is held by Catholic theologians to be an illustration of that principle of the atonement, according to which, in the theory of indulgences, the church is supposed to supply, from the inexhaustible treasure of the merits of Christ, and of the intercession for all the saints, what may be wanting to the completeness of the atonement of the less perfect but yet truly penitent sinner to whom she grants the indulgence. That this practice of relaxation, whatever may have been its real import, was to be used according to the judgment of the bishop as to the disposition of the penitent, is expressly laid down by the council of Ancona in 398, and by that of Nice in 325. In all cases, however, the person granting the relaxation was to impose certain good works as a partial substitute for the penalty which had been relaxed; and among these works, which had at first been purely personal, came by degrees to be included money payments for certain religious or charitable objects, as the building of a church, or the foundation of a monastery or hospital. The name indulgence appears to have originated late, the first recorded instance of its use being by Alexander II. in the 11th c.; but the institution itself is common to all Eastern and Western churches. In the wars of the Crusades, the giving or the contributing to service in which, 'provided it were for devotion alone, and not from motives of greed or of glory,' was accepted in the council of Clermont 'as an equivalent substitute for all penitential works,' indulgences being called 'plenary;' where a portion only of the penitential works was relaxed, it was called 'partial;' and in order to put a bar to their excessive multiplication and to other abuses, Innocent III. declared that indulgences granted for the purposes of building churches, wearing or kissing a sacred, or the like, is argued that these cannot but acquire, in the estimation of the people, an importance which is very unfavourable to penitence, virtue, faith, and piety. It is likewise urged that the whole doctrine of indulgences is founded not only on an unwarranted assumption of power given to the church, but also on a doctrine of human works and merits inconsistent with what we are taught in Scripture as to the office of Christ as a Saviour.

INDUS (Sans. Sindhu, probably from a root signifying 'to flow'), the great river that bounds Hindostan on the west. It rises in Tibet, near the sources of the kindred Sutlej, in lat. 31° 20' N., and long. 81° 30' E. The precise spot is said to be 18,000 feet above the level of the sea. On the north side of the Kailas, a Himalayan peak which overtops it by at least 4000 feet. Its general course, till it forces its way between the Himalaya proper and the Hindu Kush, is towards the northwest, being quite nearly at right angles to its general direction through the plains. On reaching Susi (near the borders of Badakshan), its most northern point, it turns southward, loses itself in the hills, and reappears at Takot in Kohistan, north of the Punjab. After a run of 870 miles, having a confluence with the Punjind, the I., instead of increasing in volume, becomes gradually less. Its basin is here narrow, so that the defilements are insignificant, while its arid sandy nature causes the river to suffer from absorption and evaporation. This operates still more powerfully from the circumstance, that the river here divides into numerous channels, many of which never return at all to the main stream, while others return which
INDUSTRIAL LIMESTONE—INDUSTRIAL SOCIETIES.

The annual rainfall in volume. This wasting of the waters is, however, a very apparent to the eye, owing to the gradual slackening of the current and the ascent of the tides. At Migan, eight miles north of Hyderabad, commences the Delta Proper, which measures 73 miles upwards, by 130 along the coast of the Gulf of Khambat. The area of the drainage—its extreme dimensions being respectively 900 miles and 750—has perhaps been over-estimated at 488,000 square miles, fully four times the extent of Great Britain and Ireland.

The value of the T. as a route of traffic is less than that of most other streams of equal magnitude. In the winter, one only of its numerous outlets is at all available for communication with the sea; and even after the melting of the spring snows, there is no passage anywhere for an ordinary sea-going vessel of more than 50 tons. Still, in another respect the river is favourable for navigation, as the fall from Atak to the sea is only 1000 feet in 940 miles.

The I. abounds with fish of excellent quality, and is infested by crocodiles. The alluvium brought down by the stream has been calculated to be sufficient for an annual formation 42 miles long, 27 miles broad, and 40 feet deep. Near Rori, a short distance from the first one of divergence of the two main stream and one of its offsets pass through a ridge of limestone, which must at one time have turned the descending floods laterally into what is now a desert, but bearing the plain traces of former cultivation.

INDUSTRIAL LIMESTONE, a singular variety of fresh-water limestone, found in Auvergne. It is formed of the cases or indusia of caddis-worms, great heaps of which have been encrusted with carbonate of lime, and formed into a hard travertine. Several beds occur, some as much as six feet thick, each cubic inch of which contains as many as ten or twelve cases. See CADDICE. The Auvergne cases are formed of the shells of a minute Paludina, so small that 100 shells may be counted in a single inch.

INDUSTRIAL ACCESSION, a phrase borrowed by the Scotch from the Roman law to denote the increased value given to a thing by labour and skill being exercised upon it. This phrase includes the case of a person building by mistake on another's land, in which case, in England, though the building was done bonâ fide, it belongs absolutely to the owner of the land, who is not bound even to pay for the materials, which he can keep, or their value; but in Scotland, the owner of the land, though entitled to the materials, would be liable to pay for their value.

INDUSTRIAL FRUITS, in Scotch Law, the produce of land which the life-renter is entitled to; called in English law, Emblements (q. v.).

INDUSTRIAL SCHOOLS. This term is used very variously, sometimes being synonymous with ragged schools, in which mechanical arts are taught; sometimes designating ordinary elementary schools, in which agricultural or some other industrial art is taught to the boys during one portion of the school day; and in the last-named country, the Glasgow Agricultural Training School has accomplished much good. See AGRICULTURAL EDUCATION. Not can it be said that the attempt to attach other industrial arts to national and parochial schools has been attended with better results. The Privy Council on Education gave special grants for many years to schools which combined industrial with literary instruction, but these grants are not continued in the Revised Code. In elementary schools for girls, industrial work, to the extent of sewing, shaping, knitting, and netting, has been almost universally introduced, and forms one of the most important subjects of the female primary education in Great Britain; but the attempt to connect with these subjects instruction in cooking, washing, and ironing, has been tried as yet only to a limited extent, and has been only partially successful. In technical schools, on the other hand, no department of the school-work seems to thrive better, partly because it enters so largely into the scheme of instruction, partly because the children are rescued from the control of parents, and left solely to the management of the school committee; for the great obstacle in the way of connecting industrial arts with ordinary schools is the unwillingness of parents to see their children engaged in such occupations during the time which ought, in their opinion, to be devoted solely to intellectual training and the acquisition of literary knowledge. The ragged schools to which we have just referred are recognised by the legislature as 'industrial schools,' and the profits of them are to be divided between the pupils and the school; the pupils are fed and clothed (wholly or partially), as well as taught the elements of an ordinary education, and the practice of some trade. By a statute passed in 1861, children under 14 found vagrant or begging, or convicted of petty offences, may be sent by a magistrate to an industrial school that has been certified by the Home Secretary. Parents also, on paying for board and lodging a small sum, may place their children in industrial schools if they can show that they are unable to control them. The Treasury may contribute to the maintenance of these schools on the representation of the Home Secretary. If a child abscond from the school before he is 15, the justices may send him back, or place him in a Reformatory School (q. v.). In 1861, there were in England 23, and in Scotland 16 industrial schools, and the number of pupils attending was respectively 1574 in the former, and 1608 in the latter.

INDUSTRIAL SOCIETIES are societies which carry on a trade, the profits of which are applied to an object of mutual benefit, resembling the object of Friendly Societies (q. v.). A statute was passed in 1802 (25 and 26 Vict. c. 87), to regulate the conduct of all societies on improvement of land, and to make the first statute having been passed in 1852. By the latest statute, all industrial societies then in existence were entitled to be registered, free of expense, by the registrar of friendly societies. Any number of persons not less than seven may establish such a society, for the purpose of carrying on any labour, trade, or handicraft, whether wholesale or retail, except the working of mines and quarries, and except the business of banking, and of applying the profits for any purposes allowed by the Friendly Societies' Acts. The rules of the society must define the object, name, and place of office of the society, and it must in all cases be registered as one of limited liability. The rules must also state the term of admittance of members, holding of meetings, voting, transferability of shares, audit of accounts, investment of capital, mode of withdrawing from society, claims of executors, application of profits, and appointment of auditors. The annual accounts must be published. A copy of the rules must be delivered to every person who demands them, on payment of one shilling. No member's interest is to exceed £200. The name of the society is to be painted conspicuously on the outside of the office, and put on all bills of exchange, bills of parcels, invoices, receipts, and letters of credit, and a penalty is incurred for neglecting these...
requirements. These societies are placed on the same footing as friendly societies in respect of the exemption from stamp duties and income-tax—of settlement of disputes by arbitration or justices of the peace. Of the societies, therefore, no one is excluded—of the power of justices or the county courts in case of fraud, and of the jurisdiction of the registrar. Any member may nominate any person into whose name his interest in the society at his death shall be transferred, but the society has the option of paying to such nominee the full value of his interest. The society may be wound up like a joint-stock company by the county court of the district, and in the event of its being wound up, past and present members are liable to contribute to the assets to an amount sufficient to pay the debts; but no past member is bound to contribute who has ceased for a year to be a member, or where the debt was contracted after he left the society, or unless the existing members are unable to satisfy the contributions necessary to pay the debts; and no member is liable to pay more than the amount, if any, unpaid on the shares in respect of which he is a member.

Every person or member having an interest in the funds is entitled to inspect the books and the names of the members at all reasonable hours at the office of the society. A general statement of the funds of the society, showing the assets and liabilities, shall be sent to the registrar once every year, and every member and depositor is entitled to demand and receive without payment a copy of such statement from the treasurer or secretary. The registrar of friendly societies in his Report (H.C. 232, 1862) says the late statute of 1862 is defective in some particulars, and a new one will be shortly required, but the substance of the law will doubtless remain as above stated.

INERTIA (Lat. 'inactivity'), a term expressive of that indifference to a state of rest or motion which is a universal property of matter, and may be expressed by saying that a body in motion will continue in motion, and a body at rest will remain at rest unless acted upon by some external force. The latter part of this principle was known to the ancients, and by them attributed to a certain repugnance to motion, which was a characteristic of all matter; but it was shown by Galileo that the former part, though true in the main, is not so. This property of matter has been called by Kepler vis inertiæ.

INESCUCEThON, in Heraldry, a single shield borne as a charge. When there are two or more, they are simply called escurceous, for an escutcheon, it is said, must always occupy the less prominent point of the shield. An inescutcheon is to be distinguished from an escurceous of pretence, which is not a charge, but a separate coat.

INFLAIBILITY, in Controversial Theology, means the immunity from error, in all that regards faith and morals, which is claimed by the Roman Catholic Church, and, at least as regards the past, by the Greek Church, as represented in the decrees of the councils which that church looks upon as ecumenical. The latter claim, however, which does not go beyond that of inerracy, or actual exemption from error up to the present time, differs widely from that of infallibility, as put forward by the Roman Church, which involves not alone an actual historical immunity from error, but also a such a positive and inviolable guarding of the person of the Church, at all times both protect against the possibility of error, and guide and direct in the faithful teaching of all necessary truth. The infallibility claimed by the Roman Church is thus of two kinds, passive and active—the first (Matt. xvi. 18), in virtue of which the church never can receive or embrace any erroneous doctrine, no matter by whom proposed; the second, in virtue of which she is charged with the function (Matt. xxvii. 19; Mal. xxvi. xxvii.) of being permanently teaching to the world the essential truths of God, of actively resisting every access of error, and of authoritatively deciding every controversy by which the oneness of belief among the faithful may be endangered. Catholics see the gift as a natural and necessary accomplishment of the authority in matters of faith with which they believe the church to be invested, and which, if not guarded in its exercise by such infallible assistance, would be but a false light, and an attractive but dangerous instrument of delusion.

Such is the notion of infallibility as claimed by the Roman Church. Two very important and practical questions, however, arise regarding it, both of which have been the occasion of much controversy even among Catholics themselves; viz., as to the subject, that is, the seat or the organ of this infallibility, and as to the object, that is, the matters to which it extends.

As to the first, all Catholics are agreed in believing that the body of bishops, morally speaking, throughout the church, acting in common with the pope, constitute the most perfect organ of the Church, and, hence, that in any way, whether as assembled in a general council or by any joint action, separated in place, their judgment is infallible. Thus, if a doctrinal decree be addressed officially by the pope to the whole church, and be at all times confirmed or tacitly accepted by the bishops, this decree is held to be infallible. In like manner, if a doctrinal decree, emanating in the first instance even from a local council, as that of a national or even a provincial council, should be universally accepted by the pope and the bishops, that decree also is held to be infallible. In a word, wherever there is found the united judgment of the pope and the bishops, all agree in accepting it as the infallible judgment of the church. But should the pope alone judge without the bishops, then arises the well known dispute of the Gallican and ultramontane divines; the latter affirming, the former denying, the papal judgment to be infallible. See PAUL I. It will be enough to say here that all alike are agreed in holding, whatever may be their several opinions as to the objective infallibility of the separate papal judgment, that it is an article of Catholic faith, long as it shall not have received the assent of the body of the bishops.

Of the matters or subjects to which the gift of infallibility extends, Catholics are agreed in one principle, that it embraces all those subjects, and those only, which are necessary for the maintenance of divine truth in the church. Hence, presupposing divine revelation, either written or oral, it embraces all questions of faith and morality, all subjects of general discipline, so far at least as to preclude the introduction, by authority of the church, of any discipline which should be injurious to faith or to morality. On the other hand, it does embrace questions of expediency or matters of fact, or abstract opinions unconnected with religion. On this point, all Catholics have been agreed. But a very celebrated dispute arose in the 17th c., on occasion of the Apocalypse of Jansenius, as to the infallibility of the church in judging of books, out of which originated the well-known Jansenist distinction of law and of fact. See JANSENISM. On this subject, it will be enough to say, that all Catholics are now agreed in recognizing as
necessary condition to the effective inofficiency, that it should extend to the judgments upon books so far as to decide whether the doctrine contained therein may not be opposed to sound faith or morality.

The arguments in favour of the inofficiency of the church, which Roman Catholics derive from texts of Scripture, are set aside by Protestants on the ground that these texts only teach the permanence of the church and the continuance of God's grace towards it (as Matt. xvi. 18; Matt. xxviii. 19, 20; &c.), and have no relation whatever to the special subject of inofficiency.—It is common also for Protestants to urge, that on the supposition of inofficiency and of the need of an infallible interpreter of Scripture, as commonly declared by Roman Catholics, there can be no value in any argument from Scripture; and that the Roman Catholic theologian, in attempting to prove the inofficiency of the church by Scripture, and the authority of Scripture by the inofficiency of the church, is involved in the sophism of reasoning in a circle.—It is sometimes added, that if God's word needs an interpreter to make it a safe rule of faith, man's word may well be supposed equally difficult to comprehend.—And the notion of inofficiency, with the whole system of which it forms an essential part, is opposed as contrary to the rational nature of man, and to that personal relation and responsibility to God which are at the foundation of all true religion.—Something is also made, in argument, of the difficulty which the advocates of the inofficiency of the church have found in agreeing as to where it is lodged.

INFAMED, or DEFAMED, in Heraldry, an epithet applied to a lion or other animal which has lost its tail, the loss being supposed to disgrace or defame it. Defamed looking backwards occurs in ancient blazons for counter-panting regardant, the lion being supposed to be flying from an enemy.

INFAMOUS, Infamy was, in point of law, formerly a ground for rejecting a witness in a court of justice; but now, in the United Kingdom, the witness is allowed to give evidence subject to comment, and to state what he can say for what it is worth.

INFAMOUS BEHAVIOUR, DISCHARGE WITH INFAMY, terms in use in the military and nautical services to designate conduct (and its penalty) which is not only opposed to discipline, but is also disgraceful in a social sense. As infamous behaviour, have always classed in all countries desertion of colours on the field of battle, failure to attempt to succour comrades in danger, cold-blooded cruelty, and other crimes which are greatly subversive of morality. If a man is found guilty of any of these crimes by a court-martial, and not sentenced to death, the sentence is ordinarily discharge—or dismissal—with ignominous or infamous. So severe an enactment adds to the force of the penalty, and stigmatises the offender for life as a disgrace to his country and his cloth.

INFANT, in English Law, means every male and female under the age of 21. As a general rule, an infant entering into contracts is to be considered incapable of entering into contracts, but not binding except at his or her option. But a contract for necessaries is always binding, and an infant may be imprisoned for non-payment of these, like other persons. The father, or, after his death, the mother, of an infant can in general only be bound for an infant's debts where some express or implied contract to pay for these has been made out; and the mere fact of the infant living in the same house is not always sufficient to imply liability, though it is generally an element for the jury. If an infant enter into trade, he is nevertheless only bound by his contracts at his option. But in all cases, if the infant, on coming of age, ratify the contract, then it is binding on him. An infant in England generally requires the consent of his parent or guardian to marry, though it is more correct to say, that if he misrepresent in the marriage proceedings, the proof of which may be indited for perjury, but nevertheless the marriage will be good, and cannot be annulled. An infant cannot make a will either of his real or personal estate. He can only sue in a court of law by a friend or procurator-familiaris, who is his father if alive, or any other friend.

In Scotland, the law differs in many respects from the law of England on this subject. The term infant is not used at all in a technical sense. All persons, if male, are in legal strictures called pupils till 14, and if female, till 12; and from 14 or 12 to 21, they are technically called minora. In general, the contracts of a pupil are absolutely void, and he is in the hands of tutors, who are either his parents, or others appointed by the court. A minor, on the other hand, may enter into contracts, but if they are to his less or prejudice, he can reduce or set them aside any time within four years after he comes of age. All minor contracts bind him, as they do other persons. Further, a minor can make a will or testament, operating on his movable estate, though he cannot alienate his heritable estate in like manner. The four years which are allowed to him as of age, is to consider whether he will set aside contracts are called quadrinumium utile; and if he can prove less, he is in that period entitled to restitution. In Scotland, also, a minor may marry as freely as if he were a major, and, indeed, he is in general his own master, or sui juris, at the age of 14 (as a female is at the age of 12); whereas in England he would be liable to have a guardian appointed to control his person till he attained 21.

INFANT SCHOOLS. Oberlin (q.v.), the pastor of Wahlbach, in France, may be regarded as the founder of infant schools. He appointed females in his own parish to assemble the little children between the ages of two and six, his object being to instruct them by conversation, by stories, pictures, maps, and to teach them to read and to sew. The first infant school attempted in this country was in connection with Robert Owen's socialistic establishment in Scotland; it was taught by Mr. Buchanan. In 1819, through the efforts of Lord Brougham and Lord Lansdowne, an infant school was set on foot in London. One of the first teachers was Wilderspin, whose labours in connection with the extension of infant schools are well known. His methods, based on the Pestalozzian system, were further matured by the Home and Colonial Infant School Society, founded in 1836. This society, by training teachers and instituting model infant and juvenile schools, has done more than any other to propagate the infant school system.

Infant schools are not yet very numerous either north or south of the Tweed; but they have certainly been more extensively encouraged in the southern than in the northern counties, by the lower rate of infant mortality than in the latter, and the less advance of the prevailing diseases. The schools are conducted on the principle that has been operated to prevent their more rapid increase—the want of means, it being necessary to devote to juvenile schools the money which can be collected for educational objects; and the defects which have hung about the system, and brought it into disrepute. Too much has frequently been attempted in the way of direct instruction. In Germany, under the names of Kleinkindschulen and Kindergärten, infant schools are numerous;
INFANTE—INFANTICIDE.

France, under the name of 'Asylums,' they are very widespread.

Infant schools, like other seminaries which are not purely professional in their aims, ought to keep in view the threefold nature of the child's mind, and appeal to its different faculties in turn. But while the intellect, the moral nature, and the imagination ought to receive their proper food, it has to be borne in mind that we contradict the laws of nature when we attempt to nourish them more powerfully and exactly than any of these; we mean the physical, and that love of play, fun, and nonsense which is connected with it, and which is peculiar to infancy, and not unconcealed even when the gravity of the school. By marching, exercises, toys, and, above all, by the judicious use of a large open playground, full provision should be made for the muscular restlessness of children, and for their love of play. The room in which they are collected should be more than a well-ordered, covered playground. In the playground, whether open or covered, order, obedience, kindness, consideration, civility, cleanliness, good-temper, are to be taught, and the moral objects of the child's mind. The moral training which may be connected with it, should be the leading ideas of the place, and to these everything else should be subordinated. Next to this, the intellectual nature of the infant has to be considered, its future anticipated, and the elements of reading taught, but with the help of such methods and books as call for the minimum of mental exertion. An infant school which has cultivated the physical nature of its children through games and exercises, and has taught them to read easy monosyllabic sentences by the time they reach the age of six, has accomplished its work well. At the same time, other means of awakening whether in school or at home, are to be used to win advantage, but under this restriction, that, if they fail to call forth spontaneous and unconscious attention, either through the want of skill on the part of the mistress to present them in an attractive form, or through some defect in the apparatus at the command of the mistress, they should at once be given up. We refer to songs of a moral or narrative kind—rhymes and nursery jingles—descriptions of objects and pictures by the children under the teacher's guidance. Lastly, the concealed purpose of being to cultivate the perceptive faculties of form, colour, number, size, &c.—and lessons in arithmetic on a ball-frame. Then, again, the infant school may be a place of amusement, and read to them fairy tales and simple stories of accident and the affections. All this may be, and actually is attained; but the qualifications in the teacher for the attainment of them are rarely to be met with. So far as these qualifications are of a moral or imaginative kind, they are natural endowments; but they may receive enlightenment and direction by a judicial system of training. In the first Report of the Home and Colonial School Society, it is truly said, 'that few situations in life require so much discretion, so much energy, so much tenderness, so much self-control and love, as that of a teacher of babes.' Without a consciousness that she possesses these qualifications, especially the last-named, no woman should for a moment contemplate the care of an infant-school mistress.

The question still remains to be considered—whether it is not more desirable as a whole, and whether the family hearth, and the fields, or the streets, do not constitute the best, because nature's infant school. Were society in a normal and healthy condition, the answer to this question would be, that infant schools are hurtful even at the best, and that, when we bear in mind the chances of their being badly conducted, they may be generally denounced as a public nuisance. But we are not in a normal state; and while infant schools proper are, perhaps, common in rural parishes, they in populous places a boon and a blessing, if not a necessity.

INFANTE (from the Lat. infans, an infant), the title given in Spain and Portugal to the princes of the royal family, the corresponding title of INFANTA being given to the princesses. Since the 14th c., however, the infant who is heir to the throne in Spain has been styled the Prince of Asturias, and the heir-apparent in Portugal, until the separation of Brazil from the mother-country, bore the title of Prince of Brazil. The personal domain of Infant or Infanta is called the Infantado, and this last comes to be the name of a district which was made a dukedom in 1475.

INFANTICIDE, the act or practice of murdering infants, which is abhorrent to modern civilisation, was common in ancient times, and now prevails among many savage and semi-savage tribes, as in Greece and Rome, and (such is the force of custom) found defenders in Plato and Aristotle. The latter, in his Politie, says the law should forbid the nurturing of the male, and where a check to population is required, abortion should be produced before the quickening of the infant. In Sparta, we are informed that the law directed, when a child was born, the father was to carry it to an appointed place, to be adopted by the elders of the community. If they perceived that it was ill- formed, or that its legs were not straight, and its book was wholesome, they returned it to its parents to be educated; otherwise, it was thrown into a deep cavern, at the foot of the mountain Taygetus; and it was said this law had a wholesome effect, for it made women with child very careful as to their eating, drinking, and exercise, and hence they proved excellent nurses. In the other Grecian republics, a similar disregard of the life of sucklings was shown. With regard to the practice among the Romans, little definite information exists, though learned authors discuss it at great length. It seems certain that it lay with the Roman father to say whether his child was to be brought up or not. The exposure of infants, indeed, was the rule, rather than the exception, in most countries in old times. Among the Norse, the child's life always hung in the balance till it had reached the age of four years; and then, if, on account of its being weak, or a daughter, he disapproved of its living, it was exposed to die by wild beasts or the weather. In modern times, the practice is cruelly common among certain peoples. Child-murder prevails to a great extent throughout the whole of the South Sea Islands. Among the Fijians, it is a system. A recent authority says, that in Vanna Levu in some parts, 'the extent of infanticide reaches nearer two-thirds than a half.' Among the Hindus, the practice of destroying children, especially females, prevailed frightfully, till it was checked in the time of the Marquis of Wellesley's rule. The Rajputs, it is said, destroy all female children but the first-born — a peculiar custom, due to its being a point of honour with a Rajput to nearly ruin himself in the marriage feast and portion of his daughter, so that he could not afford to have more than one. The Mohammedans were inclined to the same practice, but effected their object chiefly by means of abortion. In New Holland, the native women think nothing of destroying, by compression, the infant in the womb, to avoid the trouble of rearing it alive. In China, infanticide

571
INFANTRY—INFANCIMENT.

It is supposed to be common, the chief cause being
said to be the right of periodically repudiating their
wives, which is possessed by Chinamen. Some
statistics, recently published in the "Experiments
of Nancy," indicate the fearful extent to which life is
lost through this practice prevailing in so vast a
population as that of China. In all the cases above
cited, it may be assumed there was no feeling of
injustice or criminal cast of mind, but it was owing
to religious feeling of a perverted kind; in
some, to the difficulty of living; but in many, as
among the Fijians, it would appear that the mother
killed her child often from whim, anger, or insolence.

Modern civilisation deals very differently with
the subject of infanticide, for one of its maxims is
that human life, from its first to its last hour, is
sacred, and whoever wilfully puts an end to it is
a murderer, or a criminal of the same category.
Instead of encouraging the destruction of life,
modern civilisation abounds in every kind of
machinery for preserving it; however unsuccessful
the attempt. The chief cause which now leads to
infanticide is that of shame, which, however, operates
only in the case of the child being illegitimate. The
parents often incur the risk of committing the
crime of murder, to avoid social disgrace. In order,
therefore, to appreciate the force of the checks
placed by the law on the tendency to infanticides, the
law of Bastardy (q. v.), the practice of instigating
Foundling Hospitals (q. v.), and the kind and degree
of the punishments attending any attempt more or
less directly to destroy the child either before or after
birth, require to be taken into account.

The criminal law deals with the cognate offences
which make up infanticide in the following manner,
whether the child is legitimate or illegitimate. As
regards the procuring of abortion, every woman who
takes poison or other noxious thing, or uses instru-
ments or other means to procure her miscarriage,
is guilty of felony, and liable to penal servitude
for life, or not less than three years; and so is
any person who administers poison or uses instru-
ments upon the woman with such intent. Whoever
supplies drugs, poison, or instruments for the same
purpose, is guilty of a misdemeanour, and liable to
penal servitude for three years. The concealment
of bastards is also made a criminal offence. Whenever
a child is born, by any secret disposition of the
body, endeavours to conceal its birth, is guilty of a
misdemeanour, and liable to imprisonment for that
time. If the offence is a minor one, perhaps, it
is most frequently committed, or at least made the
subject of prosecution in such cases, as the attempt
to establish the larger crime of murder to the
satisfaction of a jury, is frequently foiled by the
secret sympathy shown towards the mother, who is
presumed to have been the victim of seduction, or
otherwise wronged. The existence of this offence
shews the necessity which every woman likely to
become a mother labours under of making public
her situation to some extent. As the destruction
of children may be effected by the negative fact
of not supplying food and clothing, as well as by the
positive act of wounding or ill-treating; the refusal
or neglect of a parent or other person who is bound
to supply food and clothing to the child, and
neglects to do so, thereby causing its death, amounts
either to murder or manslaughter, according to the
circumstances. Moreover, the unlawful abandoning
or selling a child under the age of two
years, whereby the life and health of the child are
endangered, is a misdemeanour punishable
with three years' penal servitude. Where a person is
charged with the murder of a very young child, it
is shown that the child has no

This is not that it breathed, or had an inde-
pendent circulation after it was separated from
the mother, but it is enough that the child was fully
born; hence, if a man strike a woman with child,
so that she prostrates herself, he is neither
guilty of murder nor of manslaughter of the child.
The judges of England, in 1849, had to deliberately
consider whether though a child was still attached
to the navel-string, the killing of it was murder,
and they held that it was, and decided that the
murder of infants, the question whether the child
was fully born, and so the subject of murder, is
generally one of medical jurisprudence, upon which
medical skill is needed to throw light, and medical
men have certain well-known tests for ascertaining
this important fact. The above offences in reference
to infanticide are punished in a similar manner as
Scotland.

One of the coroners in London recently stated
that an inquest is held daily upon the bodies
of children destroyed through the design, the neglect,
the ignorance, or the mental infirmity of the
mothers. Even when the act may fairly be regarded
as a crime, its enormity is generally greatly lessened
in the eye of the law by the consideration of the
physical condition and moral disturbance of the
parent. Where unperusal insanity supervenes, the
infant is often sacrificed during the desipr or
viciousness of the mother, but even where there is
no motive discoverable, no delusion, no explanation
afforded, no outraged feeling or fury, there has been
observed a morbid disposition to kill the newly
born child. The act is generally observed in certain of
the lower animals; it has appeared epidemically. After
the murder perpetrated by C. Cormier, five similar
atrocities were noticed. (Rev. J. Cave Brown, Indiun
Infanticide, 1857.)

INFANTRY, the foot-soldiers of an army.
Among the earliest barbarous nations, fighting on
foot has always been considered less advantageous
than fighting on horseback or in chariots; but as war
has become a science, the principal strength of armies
is found to lie in their infantry. See ARMS, TACTICS, WAR, &c.

INFECTION is distinguished from Contagion
(q. v.) by some medical writers, who would restrict
the latter word to the cases in which there must be
contact of the healthy person with a patient, while
they apply the term infectious to diseases which can
be contracted merely by the atmosphere. The distinction
is unimportant.

INFECTIOUS DISORDERS in cattle have
been made the subject of special enactment, in order
to protect the public from the calamities arising
from the spread of disease in so important an article
of food. Though passed for a temporary period,
the act 11 and 12 Vict. c. 107, has been continued
from time to time, and will probably be ultimately
declared permanent. The statute gives power to the
police to seize any sheep or lambs exposed in
any market which are infected or labouring under a
disease called the sheep-pox, or variola ovina.
The parties who so expose them are liable to
penalties, and the cattle may be destroyed; so if
any person departs diseased sheep on commons,
woods, forests, waste lands, open fields, or the
roadside.

INFENTMENT, or SASINE, a Scotch law-term,
used to denote the symbolical giving possession of
lands which was the completion of the title, the mere
conveyance not being enough. The instrument of
sasine was the notarial instrument embodying the
fact of infentment. But now the necessity of a
separate formality is unnecessary, it being sufficient
to give a notice of the conveyance in the register of
sasines in Scotland. In England, there is no similar register.
for deeds, and the title is complete when the conveyance is executed and delivered to the purchaser.

In Scotland, an _infinitesimal security_ is a temporary indenture to secure payment of some debt; and an _infinitesimal of relief_ is a similar security to relieve a cautious seller from calculations that the property is liable to change.

**INFITE.** This word is the source of much controversy and difference of opinion. Some hold that there corresponds to Infinity a distinct idea, which we are entitled to entertain and reason about, with The same certainty as that of infinite quantities played as small as we please, or as great as we please, the properties of the nature of things—of two subjective negatives converted into objective affirms (Discussions, p. 21). And Mr J. S. Mill holds a similar view. It had also been maintained by Locke that, and the active idea of the infinite, that it was only the negative of an end or termination (Essay on the Understanding, book ii. chap. 17).

The notion of the infinite has, indeed, been admitted into mathematical reasoning, a circumstance which seems to imply that we could use it with exactness, and, consequently, it could not be altogether an incompleteness or imbecility of the understanding. It appears, however, that mathematicians use the word under peculiar restrictions. They employ it in the two extremes of the circle: great and the infinitely little. "If we see a conclusion, which we can nearly attain by the use of a large magnitude, more nearly by the use of a larger, and so on without limit, that is, as nearly as we may use a magnitude as large as we please, but which is never absolutely attained by any magnitude however great, then such conclusion may be said, for abbreviation, to be absolutely true to the infinitely small." (Penny Cyc., art. "Infinite"). The very same statement might be made regarding the infinitely small, which is represented in mathematics by the symbol for nothing, although it is not the same as nothing in the strictest sense, namely, the nothing caused by subtracting a quantity from itself, as two from two. It is nothing in this sense, that, if added to a finite quantity, as 10, it produces no augmentation that can be made use of; the quantity for all purposes remains the same. We may use a magnitude as large as we please, and yet the notion of infinite magnitude is a part of the operations of the higher mathematics, and is introduced in order to compare two things naturally incomparable. Thus, in estimating the area of a curved surface, such as a circle, in straight-lined spaces, such as a square inch, the difficulty was got over by a sort of fiction, namely, by supposing the circle to be inscribed by a right-lined figure or polygon, of such a very great number of sides that they coincide to all intents and purposes with the curved circumference. The coincidence can never be perfect; but by imagining the sides to be smaller and smaller, and, consequently, more and more numerous, the distance between the polygon and the circle may become less than any assignable quantity, or, as it may be said, infinitely little, in fact, as good as nothing, so that the estimate of the area of the one will stand for the estimate of the area of the other. This device for overcoming the natural incomparability of straight and curved, and of number and motion, is the real occasion of the mathematical use of the term in question. Nor does it give any foundation for the view that would regard the infinite as a positive conception of the mind, which we may apply to objects with a conscious meaning.

This will be more apparent when we attend to the difference between two classes of negative notions. The first class includes those whose negative brings something positive; thus, not hot, brings before us positive experience, namely, cold; not white, according to what is intended, turns up either black or all other colours, which are to us as much a positive, or real, conception as white. Unjust, or not just, is the name for a distinct class of really existing actions, in contrast to the class named just actions. But what action is for opposites really existing things, are real and genuine notions of the mind; they are conceivable by us to the full extent that we are capable of conceiving anything whatsoever. In fact, the highest test of genuineness, reality, and conceivability, is the existence of a negative, which is also real and positive. Body or matter is a real conception by being opposed to space; the one resists our movements, and the other permits them. Body and space together make the extended universe, the world of externality, or objective existence; which has a distinct meaning by contrast to the inextended mind, or the subject universe. But existence, as a whole, is not a real conception, because we have nothing to oppose it to; non-existence is not a real opposite, like space to body, or mind to extension; it is only a formal or verbal opposite, made up by using the word for negation to a case that does not admit of the operations of the mind, and is total annihilation, which, for us, we cannot conceive, as we do cold or black, in their opposition to hot and white. This being so, we have nothing to affirm respecting existence as expressing the absolute total non-existence, as expressed by nothing.

Now, to which class of notions does infinite belong? Is it a real opposite to the finite, like cold to heat, or a verbal and formal opposite, like non-existence? Infinite means what has a boundary or termination, and applies strictly to body, which is always conceived by us as bounded and terminating in space. The bounded is, in fact, body (or some analogy of body, as we fancy an enclosure which we do not actually construct); the absence of bounds is free space, which is a real conception. It means scope for movement, freedom from obstruction, and its opposite is some inert matter, standing in our way, to prevent further movement. The unbounded is thus another name for space; and when we arrive at a space with no further prospect of obstruction, we may call that a boundless space, but the only meaning we have thereby is a space which no longer contains material obstruction. And we can conceive of no other end of space. Our whole experience furnishes no other contrast except those two, space and body, and where the one ends, the mind must conceive the other. We may conceive the not-extended, it is true, by passing to the subject mind, with its feelings and volitions; but within the sphere of the extended, we have no choice but between space and body. We cannot conceive the end of space otherwise than by the beginning of resistance; anything else (not being the subject mind) would be non-existence, or annihilation.

The infinite may thus be the name for an abbreviation in mathematics, but as a real notion of the mind, it means the thing lying beyond the region of our experience of matter and space.

**INFINITESIMAL CALCULUS.** See Calculus.

**INFINITIVE.** See Verb.

**INFLAMMATION.** is the most important of all the morbid processes that fall under the notice 817.
of the physician or surgeon. The most obvious symptoms or phenomena of inflammation, when it attacks an external or visible part, are pain, redness, heat, and swelling, or, in the words of Celcus, ‘rubor et tumor cum calore et dolore.’ The general characters of the process will be best understood by an assumed case. If a healthy man gets a splinter of wood or, any other foreign body imbedded in any fleshy part, he begins to experience pain at the part, and this is soon succeeded by redness of the skin, a free discharge of a fluid consisting of serum and abscess, the spot, and a sense of abnormal heat. These purely local symptoms are succeeded, if the inflammation reach a certain degree of intensity, by a general derangement of the vascular and nervous systems, to which various names, such as constitutional disturbance, symptomatic or inflammatory fever, pyrexia, &c., have been applied. If the foreign body is extracted, the probability is that all the acute process will end by swelling, and around the part at length regains its natural appearance and sensations. In this case, the inflammation is said to terminate by resolution, and this is the most favourable mode of termination. If, however, the cause of the inflammation be not removed, or intensity of the morbid process exceed a certain point, the following phenomena occur: the swelling assumes a more projecting or pointed form, the part becomes softer, and the skin at its centre, which is usually the spot projecting part, becomes white. There is a sensation of throbbing pain, and if the skin be not divided by the knife, it finally breaks, and a yellow, cream-like fluid, known as pus (q. v.), escapes, after which the symptoms rapidly abate. This termination is called suppuration.

If the original injury was very severe, and the inflammation intense, there may be actual death of the part affected. In that case, the red colour of the skin becomes purple or greenish black, the pain ceases, and the part becomes dead and putrid. This is mortification. Under favourable circumstances, this dead part, which is called a slough, spontaneously separates from the adjacent living parts by the action of the blood, and the cavity which is thus formed gradually fills up and heals.

The pain may vary from mere discomfort to intense agony. There is usually most pain in those parts in which the tension produced by the swelling is the greatest, as in bone, serous and fibrous membranes, &c. The pain occurring in inflammation is always aggravated by pressure, and by this means the physician can often distinguish between inflammatory and non-inflammatory disorders. The heat is seldom so much increased as the sensations of the patient would lead him to believe; it does not rise above the maximum heat of the blood in the interior of the body. This increase of heat depends upon the increased flow of arterial (or highly oxidised) blood to the part. The redness depends upon there being more blood than usual in those vessels in the affected part, which usually carry red blood; upon red blood entering into vessels which, in the normal state, convey colourless fluids only, or which naturally admit so few red corpuscles that they are known to cohere. The swelling depends in part upon the distension of the blood-vessels, but mainly upon the effusion of various fluids, such as blood, serum, coagulable lymph (or fibrine), and pus into the tissue of the affected part. These fluids are termed the products of inflammation.

This coagulable lymph frequently becomes organised, and many changes, some of a reparative nature (to which a reference will be presently made), and others of a morbid nature, depend upon its effusion.

Numerous observers have attempted to trace the exact phenomena of inflammation, by microscopic examination of the transparent parts of animals in which the process has been artificially excited. From observation made on the web of the frog’s foot and other transparent parts of animals by Wharton Jones, Page, and others, the following general conclusions may be drawn.

1. The external stimulus applied to the blood-vessels is a slight and gradual contraction, with a retardation of the current through them.

2. During this contraction, the blood is impeded, or altogether stops. But the vessels soon dilate to a size larger than they originally possessed, and the blood now moves through them more rapidly than in the normal state. The slight stimulus that previously prevailed, re-applied, little or no effect; but on applying a more powerful irritant, such as a minute drop of tincture of capsaicum, the phenomena of active concretion or detamation of blood become almost immediately evident and the vessel is lengthened, dilated, and tortuous, and are distended with blood which contains a great excess of red corpuscles, and is circulated with far more than the normal velocity.

3. But if the injury be still more severe—if, for example, a red-hot needle be inserted—then, in addition to the active concretion described in the preceding paragraph, there is a retardation, and finally a complete stagnation of the blood in the capillaries of the injured spot, while around it the blood moves rapidly through turgid but less full vessels.

The blood obtained by bleeding a patient suffering from inflammation of any important organ, usually presents a peculiar appearance after coagulation. In healthy blood, the clot consists of a uniform admixture of blood corpuscles and coagulated fibrine, and is of a deep red colour; but in inflammation, the upper part of the clot consists of a layer of a yellowish or whitish colour, to which the term ‘buffy coat’ is applied. This buffy coat is often conceive, or hollowed out into a cup-like form, in which case the blood is said to be both buffed and cupped. The cause of this buffy coat is still to some extent an open question; but the phenomenon is clearly due to a subsidence of the blood corpuscles, by which a layer of fibrine, forming the buffy coat, is left at the surface. Another and a more important change in the blood in inflammation is the augmentation of the fibrine, which often rises to two, three, or more times its normal quantity.

Reference has already been made to coagulable lymph or fibrine as one of the products of inflammation. This effusion of coagulable lymph is so important a process both for good and for evil, that a few lines must be devoted to its special consideration.

When coagulable lymph is diffused between membranes that are normally in contact (or nearly so) with one another, it often causes them to cohere. In this way we often have adhesions of the adjacent surfaces of serous membranes, such as the pleure, the pericardium, and the peritoneum, which materially interfere with the natural free motion of the parts, and occasion various persistent morbid symptoms. In inflammation of the iris, the pupil may be rendered irregular or immovable, or may even be closed up by the effusion of coagulable lymph. In endocarditis, or inflammation of the lining membrane of the heart, coagulable lymph may be deposited in wart-like masses on the valves, and may thus
peritonitis, for person, are nominal tracing gradually reirard underg...
verbs, with the object of representing the various aspects in which an action can appear. We find that the present tense generally has longer forms than those of the past. The adjectives commonly used are long vowels or diphthongs, inserted nasals and semi-vowels, or, lastly, reduplication. It seems that the weight given to the verbal root by these inflections is intended to exhibit the continuity of an action, and to preserve the present tense in contrast with the fleeting or momentary operation of the past. In a similar manner, the long vowels peculiar to the subjunctive in Greek (τότετο, τότετον, τότετον) are very different in expression from the root (τότετο), is so much the sign of a past time, as the symbol for an action having passed from the stage of inceptuence into that of completion.

The wear and tear of time exercises its influence as well on the radical part of words as on their inflections. Grammatical terminations of a totally different formation by corruption become obscured, and identical in shape with others of heterogeneous purport. The Latin Romance takes on itself the syllabic accent, a name of Româi (gen.), Româi (dat.), Româi (locat.), and Româi (nom. pl.); or populo those of popolo (dat.), popolo (abl.), and at a very early age that of popolo. The absence of written standard works of such a national importance as originates into the mass of a people, and to check their inclination towards misapplying or neglecting inflections which in progress of time have lost their inherent meaning; and therefore appear erroneous, accelerate the change of the inductive system into the analytical. The demand for a precise, and, so to speak, material expression of those manifold relations appropriated to inflections in ancient languages, is felt more keenly with the wearing distinctness of the latter; and sudden political revolutions, such as the invasion of Italy by Teutonic tribes, or the conquest of England by the Normans, interrupting the influence of the privileged classes of a nation, bring the struggle to a close in giving the tendency to the popular movement. Articles, prepositions, pronouns, auxiliary verbs, take in modern languages the place of inflections; and notwithstanding that these are not entirely destroyed, they have a precarious existence, and are in danger of being finally supplanted by the tendency to represent every distinct relation of words to each other by a distinct expression. The application of the as a mark of the possessive case becomes more and more limited in modern English, and the mistaken effort to supercede this relic of Saxon inflection by the substitution of the pronoun his, has only been defeated because it proceeded from learned pedants, and not from the people. The termination at as a part of the general in French verbs (present, avenir), may be called almost a dead letter, only traditionally preserved in spelling. The loss of inflections has deprived modern languages of the word in English, and power of the ancient tongues, and the periphrastic mode of expression they have adopted prevents them from arranging all the parts of a sentence with the same degree of liberty. On the other hand, they have gained in perspicuity. After all, they have only reversed the process of the combination of pronominal and auxiliary words with others; but by placing them in front, the attention of the hearer or reader is called at once to the particular modification of every possible shade of a given thought.
IN FORMA PAUPERIS—INFUSORIA.

to depress his vital powers. He should be kept in bed; his bowels should be gently opened; his skin slightly acted upon, if dry; and, if the cough be troublesome, a mustard-poultice should be applied to the chest, and an expectorant of any description. In persons of weak or broken-down constitutions, ammonia, beef-tea, and wine and water, must be given from the outset. The debility that often remains for a considerable period after the establishment of convalescence, is best met by the preparations of iron and quinine.

Few diseases increase the death-rate to such an extent as influenza, more, however, in consequence of the great number of persons who are attacked in a severe epidemic, than in consequence of its danger in individual cases.

IN FORMA PAUPERIS, a term used when a person is allowed to sue as a pauper—i.e., by getting leave to dispense with the fees of court and other costs.

INFORMATION, in English law, is used in several senses. In criminal law, an information filed by the attorney-general or master of the crown office is a substitute for an ordinary indictment, and is resorted to only in cases of such misdemeanours as tend to disturb the peace or the government—e.g., for example, libels onjudgment-decisions, or public officers, bribery at elections, &c. This information is usually called a criminal or an ex officio information, and the defendant is put on his trial in the same way as under an indictment. There are other informations, such as those called quo warranto, to test the validity of an election or appointment to a public office, &c. An information by the attorney-general in Chancery is a suit on behalf of the crown government to recover penalty for breach of any municipal or public charity, or on behalf of an idiot's or lunatic's property. The term is also commonly used to denote the written statement often but not invariably made on oath before a justice of the peace, previous to the issuing of a summons or complaint against a person charged either with a crime or an offence punishable summarily. There are also informations in the Court of Exchequer to recover penalty for breach of any municipal or public charity laws. This term is not now used technically in Scotland, except in cases of difficulty, when the Court of Justiciary orders informations—i.e., written arguments—on both sides.

INFORMER, in English law, the person who sues for a penalty under some statute, and may in many statutes which define offences—not criminal butsavouring of criminality—encouragement is often given to strangers to come forward and prosecute the offence, by giving them power to sue for the penalty for their own benefit in whole or in part. This practice has been much resorted to in modern statutes on such subjects. In England, when the informer sues in such an action, it is called a penal or qui tam action; but, in general, the penalty is not recoverable before jus tices of the peace in a summary way. In suits in Chancery, which require to proceed in the name of the attorney-general, the informer is called a relator. In Scotland, an informer is the party who sets the Lord Advocate in motion in criminal prosecutions, and the Lord Advocate is bound to give up the name of the informer, who is liable in case of malicious prosecution. See Queen's Evidence.

INFUSIONS, or INFUSA. These terms are applied in pharmacy to all solution of vegetable substances obtained without the aid of boiling. They are usually prepared by digesting in soft water (which may be either hot or cold, according to circumstances) the sliced or powdered substance in an earthenware vessel fitted with a cover. Cold water is preferable when the active principle is very volatile, or when it is expedient to avoid the solution of some ingredient in the vegetable preparation which is soluble in hot, but not in cold water. For example, in preparing the infusion of calumba, cold water is preferable, because it takes up the bitter principle (which is the essential ingredient), and leaves the starch-matter undissolved. In most cases, however, boiling water is employed. Infusions are preferred to decoctions when the active principle volatilises at a boiling heat, as in the case of essential oils; or when ebullition readily induces some chemical change, as in the case of Sena (q.v.).

Infusions may also be prepared by Percolation (q.v.), a process which is extensively employed in the preparation of tinctures. When thus prepared, they are less liable to decay than when prepared on the old system.

INFUSORIA, a class of the sub-kingdom of animals called Protozoa (q.v.). The term originally almost synonymous with Animakules (q.v.), but now very much restricted in its signification. It was first used by Ottor Friesen, who was adopted by Cuvier, who made the I. the last class of Radiata (q.v.). But their radiated structure is by no means established. No distinct trace of nervous matter has been found on which any industry by Dujardin, Stein, Lichmann and Claparède, Cohn, Lieberkühn, Rüymer Jones, and others. Many of the organisms included by Ehrenberg, as by previous naturalists, among I., are now generally regarded as vegetable (see Desmidce and Diatomaceae); whilst others, as the Ceraria (q.v.), have been discovered to be immature states of Entozoa. The Rotifer (q.v.) are now also, by very general consent, widely separated from the Polygasteria of Ehrenberg, for which alone the term I., although not unobjectionable (see Animakule), is retained; the term Polygasteria (Gr. many-stomached) being rejected, because it expresses a view of the structure of these creatures which is generally deemed erroneous. Agassiz has gone the length of proclaiming an opinion, not received by other naturalists, that the I. are all immature or larval worms. But of the forms at present known, it is at all events probable that many are those of immature creatures; it is certain that some species assume very different forms at different stages of their existence; and the whole life-history of no one species is fully known.

Some of the I. are large enough to be individually visible to the naked eye, but most of them are altogether microscopic. Their bodies are composed of serrode, a glutinous diaphanous substance, of which the outer layer sometimes forms a more or less resisting integument. The body has some well-defined form, of which the varieties are very great in different species. Many are furnished with cilia, the motion of which carries them with great rapidity through the fluid in which they live, and by means of which also currents are created in the fluid to bring food to the mouth. The mouth is very generally surrounded or largely provided with cilia. Whether these organs are under the control of will, or maintain their motion without will or even consciousness on the part of the creature, like the cilia of the epithelium in higher animals, is not determined. There is an analogy in favour of the latter opinion, and many appearances—which,
however, the phenomena of zoospores, &c., teach us to regard as possibly deceptive—in favour of the latter. Some L. instead of cilia, have a few slender filaments, which they utilise with an undulatory movement; others move by contractions and extensions of their bodies. Some have stiff bristle-like organs, which they use as feet for crawling on the surfaces of other bodies; and some have hooks, by which they attach themselves to foreign bodies.

All I. have a distinct mouth, and many have also an anal opening, sometimes near the mouth, sometimes at the opposite extremity of the body. Between these, Ehrenberg imagined that he could trace an intestine, straight in some, variously bent in others, with which along its course many small stomachs are connected; whilst in the L., having only one aperture, he supposed all the stomachs to open immediately from it. But other observers have failed to find the canal and stomachs, although Ehrenberg’s experiments, by means of fluids coloured with indigo and carmine, have been often repeated. And it seems probable that the food taken into the mouth is simply conveyed into the midst of the soft gelatinous substance of the body, being formed into pellets as it passes from the mouth through a kind of gutter in the firmer integument. The food of L. consists of organic particles of various kinds, and of any substance which substances have been reported to show a partial preference, like those of higher animals, for particular kinds of food. Many of them feed on microscopic plants and on other infusoria. Their great use in decomposition of organic nature is probably to consume organic particles, the decomposition of which would otherwise be baneful to all life, and the return of which by decomposition to their primitive elements would diminish the fertility and wealth of the sea. The number of the latter are prodigious. They are found in all parts of the world, and both in fresh and salt water, in stagnant ponds and ditches, in mineral and hot springs, and in moist situations. Any infusion or other liquid containing vegetable or animal matter, if left exposed to the atmosphere, is sure to be full of them. Their multitudes are so great that leagues of the ocean are sometimes tinged by them. Some, which, instead of swimming freely, like most of their class, become surrinded in a gelatinous substance, are found adhering together in masses sometimes four or five inches in diameter, although the individual animals are so small that a cubic inch of the mass may contain hundreds of them. The number contained in a single cup of potrd water may exceed in number the whole human population of the globe!

The organisation of the L. is still very imperfectly known. There appears in many of them a cavity not far from the mouth, the contractile space—variously regarded as a cavity without proper walls, or as a vesicle—from which branches sometimes radiate through the substance of the body, and which, being capable of contraction and expansion, is regarded by some as the centre of a kind of vascular system. It is with considerable probability regarded as furnished with proper walls. There is also, probably in all the L., another organ, even of great importance, although its use is still uncertain, called the nucleus, which is usually roundish or a little elongated, sometimes much elongated and band-like. It is enveloped in a membrane, and is more compact than the surrounding substances. In the multiplication of these animals by spontaneous division, a fission of the nucleus always takes place. Each of the halves becomes furnished with a complete mouth, set of cilia, and other organs. The division, in the same way, is sometimes longitudinal, sometimes transverse, perhaps alternately longitudinal and transverse. The multiplication of the L in this way is extremely rapid. A Paramecium, well supplied with food, has been observed to undergo division every 24 hours, from which would result 10,000 individuals in a fortnight, or 268,435,456 in four weeks. Reproduction also takes place by gemmation; buds or gemmules forming on the outer surface of the body, and gradually assuming the shape of the parent, which is eventually thrown off and attains to its full size till after separation. Meiosis extraordinary is another mode of reproduction by encysting or encopulation. The animal contracts, closes its mouth, becomes surrounded by a viscid secretion, and finally by a membrane, becomes attenuated, and dissolves, all but the nucleus, into a mere liquid containing granules, which afterwards form within the cyst a new infusorium, different in form and appearance from that by which the cyst was produced. The metamorphoses of the L. have been traced to a certain extent in some kinds, but not fully in any. Whether any truly sexual propagation takes place, has not been perfectly ascertained, although the observations of Balfour have made it extremely probable as to some of them. A reproduction, different from all that has yet been mentioned, has been observed to take place in some, by the formation of internal gametes, which unite with external ones, and a specimen of the subject is still involved in doubt; nor is it improbable that there may be amongst these minute creatures a production of real eggs, which have hitherto escaped observation. 

In the integument of some L., very minute fusiform bodies are thickly imbedded, called trichocysts, which are capable of throwing out long filaments. Their use is unknown, although they are supposed to be analogous to the stinging cells of some animals. The filaments are thrown out when the animal is subjected to annoyance by the drying up of the liquid in which it lives, or by the application of some irritant liquid.

INFUSORIA, FOSSIL. See DIAEOMACE.

INGLEMANN, Bernhard Severin, one of the most distinguished poets and novelists of Denmark, was born May 28, 1789, in the island of Falster. His literary career may be divided into three distinct periods. During the period from 1811 to 1814, embraces his best lyric productions, viz., the collection of poems entitled Proence (1812), and the allegorical epic of De Sorte Riddere (1814); while his labours during in 1822, were marked by the appearance of numerous tragedies, which have maintained their place on the national stage, and among which the best are his Manesnieul, Blanca, Rodten i Orsten (1815); Hyrden af Tobol, Reinduk, Underbarnet, Loverdorfera (1816); and Tusso af Brefinde (1819). Since this period, his writings have been characterised either by a leaning to historical disquisition, or a strongly religious bias. His admirable epic poem of Falduen des Store og hans Mand (1824) was the prelude to the various historical novels, in which, taking Walter Scott for his model, he endeavoured to portray the social life and habits of his own country in the middle ages. Falduen Skatten (1826), and Erik Meveds Barnes (1828), are generally regarded as the best of these productions, may compete favourably with some of the most successful efforts of his great model: while even the less popular of his historical poems, Hans Erik og de Fredlose (1833), and Prulda Otto og Hans Samtid (1835), may justly entitle him to rank among the first novelists of the day. The poems of Dronning Margrethe (1836) and Hefter (1854) are novels in verse, sometimes long poems, sometimes long incidents of Danish national history and traditions.
INGERSOLL—INTA.

rank among 1st's most successful efforts. The religious element in this writer's mind has found expression in various productions of considerable merit—as, for instance, in his collection of anthems and psalms, Horae mysticae (1829), in his rendering of some of the symbolical or traditional legends of the church in his Blade of Jerusalem's Skomayer's Lamenbeh (1833); Solomon's Ring (1839); and in his allegorical poem, Gudulebit (1836). It holds the chair of professor at the Royal Academy of Sorle, near Copenhagen. His collective works have been published in 38 vols., 1857, Copenhagen, and the greater number of his prose works and many of his poems have been translated into various other languages.

INGERSOLL, CHARLES J., an American statesman, was born in Philadelphia, October 3, 1782. His father, Jared Ingersoll, was an active partisan in the American revolution, and a member of the convention which adopted the Federal constitution. Charles J. L received a liberal education, which was completed by European travel. In 1794, he produced the tragedy of Iseley and Elymus, and in 1808, a strong political pamphlet in defence of the democratic policy of Mr Jefferson, and a satirical review of American politics, entitled Inseley's Life (1828). He published two historical Sketches of the War of 1812 (1845—1852). He was elected to Congress in 1812, and in 1814 advocated, in a powerful speech, the principle that 'free ships make free goods.' He was U.S. District Attorney for Pennsylvania from 1815 until 1825, and from 1840 to 1846 again represented his district in Congress. In 1847 President Polk appointed him Minister to France, but the Senate did not confirm the nomination. From this time until his death, May 11, 1862, he took no part in politics.

INGOLSTADT, or INGOLDESTATE (anciently Aurinum, and by the Latin writers of the 16th c. called Auripolis and Chrysopolis—i.e., 'the golden city'), a town and fortress of Upper Bavaria, is situated in a fertile district, on the left bank of the Danube, which is here crossed by a stone bridge, 46 miles north-north-west of Munich. It contains nine churches, a hospital, and a castle. Cloth, playing-cards, and leather are manufactured; furs and furs and a trade in corn are carried on. Pop. 15,002.

L is an ancient, melancholy-looking town, too large for the number of its inhabitants. A university was founded here in 1472, which reckoned Reischlin, Albrecht Dürer, and other eminent scholars among its professors; it was removed, however, to Landshut in 1800, and to Munich about six years after. At this university, in the 16th c., Urb. Righaus the poet, known by the name of Dr Faustus, studied. L. was the first German town at which the Jesuits were permitted to establish themselves, and to teach publicly from the university chairs. Loyola gave it the title of 'his little Benjamin.' After the suppression of the order in 1773, Alkan Weible was presented to the See of the Limmat (p. v.). In 1827, the fortifications of L. which had been destroyed by the French in 1800, were restored upon a large scale, the two forts on the left bank of the river being especially distinguished for their elegance and strength.

INGRAILED. See ENGRAINED.

INGRES, JEAN DOMINIQUE AUGUSTE, an eminent French painter, was born at Montauban, 15th September 1780, studied under David (p. v.), and subsequently went to Rome. Here he resided for fifteen years, after which he spent four years in Florence, by which time his fame was so well established, that he was called to the School of Fine Arts in Paris as the successor of Denon. In 1829, he succeeded Horace Vernet as Director of the Academy at Rome; and in 1845, he was made Commander of the Legion of Honour. His merits as a painter have been very highly canvassed, and unanimity of opinion is yet far from having been attained. He occupies a sort of middle place between the classic and romantic schools, but rather inclines to the former. His admirers praise him for correct design, ideal composition, and some painting. Among his numerous pieces may be mentioned 'Raphael et la Fornarina,' 'Romulus, Vainqueur d'Acron,' 'Virgile lisant son Enarde a Auguste et a Octavie,' 'La Mort de Léonard de Vinci,' 'Le Veau de Louis XIII,' 'L'Apothésè d'Homère,' Stratonice,' 'Jésus au Milieu des Docteurs,' Moïse dans son Cabinet,' and 'L'Apothésè de Napoléon l.' with a motto flattering enough to the present Emperor of the French, In sanguine redactus. At the Paris Exhibition of 1835, L. had a whole salon to himself.

INGRIA. See ST PETERSBURG, GOVERNMENT OF.

INGROSSING, or ENGROSSING, a deed means, in Law, the writing it out in full and regular form on parchment or paper for signature. The person who engrosses is usually a law-stationer or clerk. In Scotland, the corresponding term is 'extending a deed,' and the title of the person who does so must be named in the testing clause, which is not necessary in England.

INGULPH, Abbot of Crowland, long considered the author of the Historia Monasterii Croylandensis (History of the Monastery of Croyland or Crowland, in Lincolnshire); it is supposed to have been born in London about 1030 A.D. According to the account of his life in his History, he studied oratory and philosophy at Oxford; became a favourite of Elgitha, the wife of Edward the Confessor; visited Duke William of Normandy at his own court in 1051; and, after a disastrous pilgrimage to the Holy Land, entered a Norman monastery. Here he remained till 1076, when he was invited to England by the Conqueror, and made Abbot of Crowland, where he died December 17, 1106. The Historia Monasterii Croylandensis was printed by Savile at London in 1596, and in a complete edition by Bale at Oxford in 1634. It has been translated into English for both the National Library by Riley. Some writers even of the last century questioned the entire genuineness of the book; but their scepticism did not proceed further than the hypothesis of interpolations by a later writer; but in 1830, the late Sir Francis Palgrave, in an article in the Quarterly Review, endeavoured to prove that the whole so-called History was little better than a novel, and was probably the composition of a monk in the 13th or 14th century. His conclusions have been, on the whole, almost universally adopted.

INHERITANCE. See HEIRS, INTEREST, WILL, SUCCESSION.

INHIBITION. In Scotch Law, is a writ which is issued in order to prohibit a person from alienating his heritable estate until the debt of the creditor is paid.

INIA (Inia Bolivianus), a cetaceous animal, of the family Delphinidae, in form resembling a dolphin, with a long and slender snout. It is the only known species of its genus, and is one of the few cetacea which inhabit fresh water. It is found in some of the upper tributaries of the Amazonas, and in the lakes near the Cordilleras. It is from seven to twelve or fourteen feet long. The I. feeds chiefly
INITIALS—INK.

Inia (Bolivienia).

It is pursued for the sake of the oil which yields It is generally found in little troops of three or four. The females show great affection for their young.

INITIALS. Though in general it is usual and regular in all legal deeds and writings for a party to write his full Christian name and surname, yet in many cases, especially in documents of a mercantile nature, signature by initials will bind equally with the full signature.

INJECTIONS. This term is applied in medicine to fluids thrown into the passages or cavities of the body by means of a syringe or elastic bag. The fluids thus injected into the rectum or lower bowel are termed Clysers (q.v.). The injection of a dilute solution of salt into the veins has been found to be of great service in even advanced cases of Asiatic cholera. The injection of blood into the veins is described in the article TRANSFUSION OF BLOOD.

INJUNCTION, a writ in English law, by which the Court of Chancery stops or prevents some inequitable or illegal act being done. The writ is peculiar, in general, to the Court of Chancery, though to a limited extent it is now introduced into common law. If the party disobeys the injunction, he may be attached for contempt of court, and imprisoned till he obeys. If he obeys it, he may apply to have the injunction dissolved. In Scotland, a remedy of a similar kind is called an Interdict (q.v.).

INK. The most important kinds of ink may be included in the following heading—Writing Ink and Printing Ink.

1. Writing Ink.—The composition of the ink used by the ancients is not well understood; it is however evident that their inks exceeded ours in blackness and durability. Mr Underwood (who read a paper upon the subject of ink before the Society of Arts in 1857) thinks that some old ink was merely a carbon pigment, like the Indian ink of the present day, while other kinds were veritable dyes of iron and acids (true chemical compounds), with the addition of a good deal of carbon.

The essential constituents of ordinary black ink are galls, sulphate of iron (popularly known as green vitriol or green copperas), and gum; and the most important point is the regulation of the proportion of the sulphate of iron to the galls. If the former is in excess, the ink, although black at first, soon becomes brown and yellow. The gum is added to retain the colouring matter in suspension, and to prevent the mixture from being too fluid. The following prescription by Professor Brande yields a very good ink: "Boil six ounces of finely bruised Aleppo galls in six pints of water, then add four ounces of clean and well crystallised sulphate of iron, and four ounces of gum-arabic. Keep the whole in a wooden or glass vessel, occasionally shaken. In two months, strain, and pour off the ink into glass bottles." The addition of a little creasote is useful as a check to the formation of mould. Stephens's ink—a blue liquid, which is a few hours after its deposition on paper becomes of an intense solution of oxalic acid—which is one of the most soluble of our writing fluids. It consists essentially of gallo-tannate of iron, dissolved in sulphate of indigo, while in ordinary ink the colouring matter is merely suspended by means of the gum. Runge, a German chemist, has discovered a simple and cheap black writing fluid, prepared from chromate of potash and a solution of logwood, which possesses the properties of forming no deposit, of adhering strongly to the paper, of being unaffected by exposure to water or acids, and of neither acting on, nor being acted on by steel pens.

Various receipts for indelible inks have at different times been published. Dr Normandy asserts that the ink obtained by the following combination cannot be obliterated or defaced by any known chemical agent: Twenty-four pounds of Frankfurt black (which is supposed to be a charcoal obtained from grape and vine lees, peach kernels, and bone-shavings) must be ground with mealcake, formed by adding twenty pounds of gum-arabic to sixty gallons of water, and the mixture strained through a coarse flannel; four pounds of oxalic acid are then added, together with as much decoction of cochineal or safflower, which will give the required tinge.

Red Inks are of two kinds, one variety consisting essentially of the tinctorial matter of Brazil-wood, and the other being prepared from cochineal or safflower.

Stephens's red ink, which is one of the best of these preparations, is obtained as follows: To a quantity of common carbonate of potash, soda, or ammonia, twice its weight of crude arcel in powder. When the effervescence has ceased, decant or filter the solution from the insoluble matter. To this fluid add by measure half its quantity of oxalate of alumina, prepared by dissolving damp, newly precipitated alumina in as small a quantity as possible of a concentrated solution of oxalic acid. The mixture thus prepared is next coloured, when cold, with bruised or powdered cochineal, and after standing for forty-eight hours, is strained, when it is fit for use. (Muspatt's Chemistry, vol. ii. p. 378.)

Blue Inks are now chiefly made either directly or indirectly from Prussian blue. Stephens's unchangeable blue ink is formed by dissolving this salt (which should be first well washed in a dilute mineral acid) in a few ounces of water containing a little of a fluid of a particular nature. Prussian blue is the basis, is unaffected by any of the numerous physical causes which operate injuriously on black ink, unless it be exposed to a strong light, when the iron (which exists as a sesquioxide in Prussian blue) becomes deoxidised, and causes the colour of this ink to fade; but on removing the writing from the influence of light, the colour is restored.

Purple, green, and yellow inks have been formed by various chemists, but they are not of sufficient importance to claim a notice in this article.

Sympathetic inks leave no trace of colour upon the paper, but when exposed to heat or chemical action of some kind, become more or less distinctly apparent. The following are a few of the principal kinds of this class of compounds. On writing with a solution of sugar (acetate) of lead or of tannate of bismuth, and washing the paper with a solution of hydroxyl sulphate of gum (sulphated hydrogen), the letters come out black. On writing with a solution of nitrate of cobalt, and washing the paper with a solution of oxalic acid, the letters come out blue. On writing with a solution of sulphate of lead, and washing the paper with a solution of sodium of potassium, the letters come out yellow; or on writing
INKERMANN—INN AND INNKEEPER.

with a dilute solution of chloride of copper, and gently heating the paper, the letters which were previously invisible assume a beautiful yellow tint, which disappears on cooling. On writing with a solution of arsenite of potash, and washing the paper with a solution of nitrate of copper, the letters come out green.

2. Printing Ink is a soft glossy compound, altogether different in its composition from the inks which have been already described. The following are employed, both of which differ strongly (the paper already referred to), the necessary conditions of a good printing ink: 1. It must distribute freely; 2. It must have much greater affinity for the paper than for the type; 3. It must dry almost immediately on the paper, but not too fast; 4. It must be employed, and tone, employed, indigo black and lampblack, which now somewhat resembles Canadian balsam. The colouring matter—which is lampblack for black ink; carmine, lake, vermillion, &c., for red ink; indigo or Prussian blue for blue ink; lemon and orange chrome (chromate and bichromate of lead), or gamboge, for yellow ink, &c.—is then added to the hot mixture, and the whole is drawn off, and finally ground into a smooth uniform paste.

In Lithography, a seriving and a printing ink are employed, both of which differ strongly from the compounds already described. The writing ink is composed, according to Muspratt, of the following materials: shell-lac, soap, white wax, and tallow in certain proportions, to which is added a strong solution of gum-mastic, and it is coloured with lampblack; while the printing ink, which is employed to take impressions on paper from engraved plates, with a view to their transference to the stone, is composed of shell-lac, gum-mastic, black pitch, and lampblack.

INKERMANN, a small Tartar village in the Crimea, is situated near the eastern extremity of the harbour of Sevastopol. It is memorable for the battle which took place there, during the Russian war, between an army of Russians 60,000 strong, and detachments of allied forces, consisting of about 14,000 troops actually engaged. At about six o'clock on the morning of the 5th November 1854, the Russians, who had marched westward from Sevastopol, along the south shore of the harbour, and whose movements were concealed by the darkness and a thick, drizzling rain, appeared crowding up the slopes of the plateau to the south, on which the allies were posted. Here a handful of men, about 1000 strong, a portion of the 'Household Guards,' made a most heroic stand for six consecutive hours against a body of Russians that was probably ten times as numerous. Reinforcements, both English and French, coming up to the rescue, the Russians were finally driven from the field.

INLAND BILL of Exchange means a bill of exchange drawn by and upon persons living in the same country. The rules applicable to foreign bills differ in some respects from those applicable to inland bills. By a recent statute, all bills drawn by persons in Scotland on persons in England or Ireland, and vice versâ, are to be treated as inland bills.

INLAYING is the art of decorating flat surfaces by the insertion of similar or different materials; thus, wood of one colour is decorated by inlaying with others of different colours: to this kind of inlaying the French term marguerite is now generally applied. Metal of one kind is inlaid with other kinds, and often very beautiful effects are produced. When steel is inlaid with gold or brass, it is usually called Damascene work. One variety produced in India is called Koft-gori—in this, the inlaid metal, usually gold, occupies more of the surface than the metal forming the ground. Another beautiful variety of Indian inlaying is called Tuten-gi, in which agate or Bedouk work, which consists in making the article to be inlaid, most frequently a hookah bowl, of an alloy consisting of copper one part to pewter four parts. This is hard, but is easily cut; the pattern is then engraved, and little pieces of thin silver cut to the desired forms are exquisitely hammered into the spaces thus cut out to receive them. Ivory, pearl, shell, bone, tortoise-shell, are favourite substances for inlaying wood; and marble or inlaid marble is inlaid with an immense variety of coloured stones. In the art of stone-inlaying, the Florentines have long held the palm; their favourite work is black marble, with inlaid figures of brilliant-coloured stones; this work is called 'pietra dura,' or 'marble-inlay,' one of the most beautiful works of this kind, excelling the Florentine, is now made in the Imperial works at St Petersburg, where the art has of late been sedulously cultivated by the Russian government. This art was always a favourite one in Delhi and Agra, where some of the most exquisite work is still produced. Usually, in the Indian work, white marble forms the groundwork, and the figures are formed of carnelian, Jasper, agate, jade, lapis-lazuli, and other costly hard stones. No stone-inlaying has ever rivalled the inlaid marble walls of the celebrated Taj Mahal, the tomb of the sultana of Shah Jehan, at Agra. The designs are very artistic, the execution almost marvellous, and the harmony of the colour produced by the different stones employed most beautiful. Many other materials than those mentioned are used for inlaying; and there is a style of inlaid-work in which small squares of coloured stone, glass, or pottery are made to form pictorial and artistic decorations; this is called Mustakr-ink (q. v.).

INLET, an arm of the sea open only on one side, and stretching into the land, is distinguished from a bay (q. v.) only by its smaller size, as a haven is, again, by still smaller dimensions. It may arise from an inlet. Examples of inlets are seen in the indentations of the west coast of Norway; as of bays in the deeper and wider indentations of the coast of Italy.

INN (ancient Eanna), a river of Germany, the most important Alpine affluent of the Danube, flows in the south of the Swiss canton of Grisons, at a height of 4293 feet above sea-level, and flowing north-east through that canton forms the valley of the Engadine. It maintains generally a north-east course to its junction with the Danube. Leaving Switzerland, it enters the Austrian dominions at the village of Finstertürlin, flows through the crown-land of Tyrol, and crosses the south-east angle of the Bavaria, after which, forming the boundary between Bavaria and Upper Austria, it enters the Inn at Passau, after a course of 285 miles. Its principal affluent is the Salza from the south. It is regularly navigable from the town of Hall, eight miles below Innlin, to the mouth of the Danube. At its junction with the Danube, the Inn is broader than the Danube itself.

INN AND INNKEEPER (see HOTEL). In point of law, an inn is merely a house of entertainment for travellers, which any person may set up without licence like any other trade. It is when excisable
INNATE IDEAS—INNOCENT.

We have seen above that a licence is required. Public-houses and ale-houses are, however, synonymous terms with inns, for the innkeeper almost invariably finds it expedient to obtain the necessary licence to sell spirits and beer. As to these licences, see BEER ACTS AND PUBLIC-HOUSES. The rights and duties of innkeepers irrespective of the licence will here be noticed. It may be observed, in the first place, that when a public-house, or beer-houses, yet beer-houses are not so, the latter being merely shops for selling beer and a few other liquors, the distinguishing characteristic of the public-house being that refreshment as well as lodging may be had on the premises by all comers. Taverns are chiefly places for the sale of wines and liquors; victualling-houses, for the sale of victuals; coffee-houses and hotels are also varieties, all of which may or may not be inns, according, as they do or do not hold themselves out to give meat, drink, and lodgings to all travellers; and it is not at all necessary that any sign-board be put up to distinguish the inn.

One of the incidents of an innkeeper is, that he is bound to open his house to all travellers without distinction, and has no option to refuse such refreshment, shelter, and accommodation as he possesses. Provided the person who applies is of the description of a traveller, and able and ready to pay the customary hire, and is not drunk or disorderly, or tainted with infectious disease. He is, of course, bound only to give such accommodation as he has. If the traveller has a horse and luggage, the innkeeper is bound to receive these also, if he has accommodation, provided the traveller himself intends to lodge there as a guest. But the traveller is not entitled to select whatever room he pleases; and if he does not accept of the room assigned to him, he cannot detain the person of his guest until payment is made, for if so, a man might be imprisoned for life without any legal process or adjudication. While, however, an innkeeper has this remedy for his scoundrels, he is not liable to great responsibility for the safety of his guests and their goods. By the Roman law, under the edict nautae, canpones, stabalarii, he was bound to restore safely whatever goods of his guests were intrusted to him, unless some damnum faiote, or some act of God, prevented his doing so. This rule has been adopted by the law of England. Hence, if the guest be robbed of his goods at the inn, the innkeeper is liable, unless the robbery was caused by the guest’s servants or companion, or by his own gross negligence, as, for example, by leaving a box containing money in the commercial-room, after exposing its contents to the bystanders. So the innkeeper will be excused if the guest took upon himself the care of his own goods, yet the guest does not take that charge by merely accepting from the landlord the key of the room, though that may be an element in the question. A guest who takes all reasonable precaution—as, for example, locking his room-door—and is yet robbed, has therefore a good claim on the landlord for indemnity; and the landlord will not escape liability by putting up a notice in his rooms, that he will not be responsible for such goods as the guests would have no protection, for they are very much at the mercy of the keepers of such houses.

It has been attempted to extend the common law liability of innkeepers for the safety of the goods of their guests to ordinary lodging-house keepers, but the attempt has held that an ordinary boarding-house keeper or lodging-house keeper is only responsible for ordinary care, i.e., such care as he takes of his own goods. He must, it is true, be careful in selecting his servants, but he is not bound absolutely to return the goods safe merely because they were in his house along with the lodger.

In Scotland, the Roman rule of law as to the responsibility of innkeepers for the safety of the guest’s goods has been also adopted; and the other heads of law are substantially the same as in England, except that no indictment would lie in Scotland against an innkeeper for refusing a guest. But the substantial remedies are the same.

INNATE IDEAS. See COMMON SENSE.

INNER HOUSE, the name given in Scotland to the higher divisions of the Court of Session (p. 402).

INN TEMPLE, one of the four Inns of Court in London having the exclusive privilege of calling persons to the English bar. See INN OF COURT.

INNISCATORY. See Scattery Island.

INNISHERKIN, a small island on the south coast of Ireland, belonging to the county of Cork, from the shore of which it is separated by a channel a quarter of a mile in width, is about one mile in circumference. It is inhabited, and contains some good and extensively worked slate-quarries. Pop. upwards of 1000.

INNOCENT, the name of 13 popes, the most remarkable of whom are the following. INNOCENT I, a native of Albanu, was elected Bishop of Rome in 399; in 402, he was unanimously chosen pope, and died in 417, that of Innocent I. forms the most important epoch in the history of the relations of the see of Rome with the other churches, both of the East and of the West. Under him, according to Protestant historians, the system of naming legates to act in the name of the Roman bishop in different portions of the church originated; while Catholics at least admit that it received a fuller organisation and development. He was not rigorous in enforcing the celibacy of the clergy. He maintained, with a firm hand, the right of the Bishop of Rome to receive and to judge appeals from other churches, and his letters abound with assertions of universal jurisdiction, to which the Roman clergy pretended. The pope, after the death of the Roman primacy, and from which Dean Milman infers that there had already ‘dawned upon his mind the conception of Rome’s universal ecclesiastical supremacy, dim as yet and shadowy, yet solid and comprehensive in its outline’ (Latin Christianity, i. p. 87). Innocent I. died in 417.

INNOCENT III. (Lothario Conti), by far the greatest pope of this name, was born at Anagni in 1161. After a course of much distinction at Paris, Bologna, and Rome, he was made cardinal; and eventually, in 1198, was elected, at the unprecedentedly early age of 37, a successor of Pope Celestine III. The pontificate is justly regarded as the most significant point in the temporal career of the Church; it was the realisation of the spiritual supremacy of the Roman see; and it is freely avowed by the learned historian of Latin Christianity, that if ever the great idea of a Christian community with a pope at its head, was to be realised, ‘none could bring more lofty or more various qualifications for its accomplishment than Innocent III.’ (iv. p. 9). Accordingly, under the impulse of his ardent but disinterested zeal for the glory of the church, almost every state and kingdom was brought into subjection. In Italy, during the minority of Frederick II. (son of the Emperor Henry VI., king
of Italy), who was a ward of L.'s, the authority of the pope within his own states was fully consolidated, and his influence among the other states of Italy was confirmed, and extended. In Germany, he adjudicated with authority upon the rival claims of Otto and Philip; and a second time he interposed effectually in behalf of his ward, Frederick II. In France, at the Fete de la Somme, the invested Ingerburga, he compelled her unworthy husband, Philip Augustus, to dismiss Agnes de Meranie, whom he had unlawfully married, and to take back Ingerburga. In Spain, he exercised a similar authority over the king of Leon, who had marred within the prohibited degrees. The history of his conflict with the weak and unprincipled John of England would carry us beyond the space at our disposal. If it exhibits L.'s character for consistent adherence to principle, and his lofty indifference to the suggestions of expediency, in a less favourable point of view than his other similar contests, it at the same time displays in a stronger light the extent of his pretensions and the completeness of his supremacy. In Norway, he exercised the same authority in reference to the usurper Swevo. In Aragon, he received the fealty of the king Alfonso. Even the king of Armenia, Leo, received his legates, and accepted from them the grant of the duchy, and of the right of interdict, and finally of interdict, that nothing might be wanting to the completeness of his authority throughout the then known world, the Latin conquest of Constantinople, and the establishment of the Latin kingdom of Jerusalem, but that his authority might be unimpeached. The shadiness of the eastern rivals of his power, spiritual as well as temporal. Pursuing consistently the great idea which inspired his entire career, his views of the absoluteness of the authority of the pope, and the duty of the rulers to respect and repress, it was at his call, therefore, that the crusade against the Albigenses was organised and undertaken; and although he can hardly be held responsible for the fearful excesses into which it ran, and although at its close he used all his endeavours to procure the restitution of the lands of the young Count of Toulouse, yet it is clear from his letters that he regarded the undertaking itself not merely as lawful, but as primarily the duty of the Church, and even the laity. As an ecclesiastical administrator, L. holds a high place in his order. He was a vigorous guardian of public and private morality, a steady protector of the weak, zealous in the repression of simony and other abuses of the time. He prohibited the arbitrary multiplication of religious orders by private authority, but he lent all the force of his power and influence to the remarkable spiritual movement in which the two great orders, the Franciscan and the Dominicans (q. v.), had their origin. It was under him that the celebrated fourth Lateran Council was held in 1215. In the following year, he was seized with his fatal illness, and died in July at Pergia, at the early age of 58. His works consisting principally of letters and sermons, and of a remarkable treatise On the Misery of the Condition of Man, were published in two vols. folio (Paris, 1692). It is from these letters and decretales alone that the character of the age, and the true significance of the Church's policy of this extraordinary man, can be fully understood; and it is only from a careful study of them, that the nature of his views and objects can be realised in their integrity. However earnestly men may wish it, no student of medieval history will refuse to accept Dean Milman's verdict on the career of Innocent III., that 'his high and blameless, and, in some respects, wise and gentle character, seems to approach more nearly than any one of the chiefe succession of Roman bishops to the ideal light of a supreme pontiff,' and that 'in him, if ever, may seem to be realised the churchman's highest conception of a vicer of Christ' (Latin Churchkandy, iv. 277).

INNOCENTS XI. (Benedetto Odescalchi), elected in 1676, was one of the most distinguished among the popes of the 17th century. He was a vigorous and judicious reformer, and his administration is entirely free from the stain of nepotism which had marred the fame of many of his predecessors. But his historical celebrity is mainly owing to his contest with Louis XIV., which illustrates as well the personal character of the pontiff, as the peculiar spirit of the age. The dispute began from an attempt on the part of the pope to put an end to the abuse of the king's keeping sees vacant, in virtue of what was called the Droit de Regale, and appropriating their revenues. The pope accordingly attempted to deny forth the celebrated declarations of the French clergy as to the Gallican Liberties. See Gallican Church. But the actual conflict regarded the immunities enjoyed by the foreign ambassadors residing in Rome, and the legates of all the rival churches claimed not only for their own residences, but also for a certain adjoining district of the city. These districts had gradually become so many foci of crime, and of frauds upon the revenue; and the pope, resolving to put an end to so flagrant an abuse, gave notice that, while he would respect the rights of the existing ambassadors, he would not thereafter receive the credentials of any new ambassador who should not renounce these abusive claims for himself and his successors. This liberal and lenient course of the pope was not denounced by the pope. But it was with France that the crisis occurred, on the death of the Marechal d'Estrees. The pope renewed his notice in May 1687. Louis XIV., on the other hand, instructed his new ambassador to maintain the dignity of France, and sent a large body of military and naval officers to support his pretensions. L. persisted in refusing to grant an audience to the ambassador. Louis, in reply, seized on the papal territory of Avignon, and threatened to send a fleet to the coast of the Papal States, but L. was immovable; and in the end, the ambassador was compelled to return with his credentials unopened, nor was the dispute reversed till the following pontificate. L. died in 1689.

INNOCENTS, HOLY, FEAST OF, one of the Christmas festivals, held in the Western Church on December 28, and in the Eastern on the 29th, under a title similar to that of the Latin festival. It is intended to commemorate the massacre of the children 'from two years old and upward' at Bethlehem. See HEROD. These children are referred to as martyrs by St Cyprian, and still more explicitly by St Augustine; and it is to them that the exquisite hymn of Prudentius, Salve Florea Martyrum, is addressed. The concurrence of the East and West in celebrating the festival is an evidence of its antiquity. In the modern church, this feast is celebrated as a memorial of the massacre by the young, and many curious customs connected with it prevail in Catholic countries. One of these is, that in private families the children are on this day privileged to wear the clothes of the elders, and in some sort to exercise authority over the household in their stead. So also, in communities of nuns, the youngest sister becomes for this day superiress of the house, and exercises a sort of sportive authority even over the real superiors. 165
INNOMINATE ARTERY—INOCULATION.

INNOMINATE ARTERY (Arteria innominata) is the first large branch given off from the arch of the aorta. It varies in size from one inch and a half to two inches in length, and divides into the right carotid and the right subclavian arteries. See CIRCULATION, ORGANS OF. This artery, through which all the blood to the right side of the head and neck, and to the right arm, flows, has been tied by several surgeons for aneurism of the right subclavian, but the operation has never been successful. An important fact has, however, been established, viz., that the circulation of the blood in the parts supplied by this large vessel, is re-established by Anastomosis (q.v.) after the operation.

INNOMINATE BONE. See PELVIS.

INNOVATION, or NOVATION, a name sometimes given in the law of Scotland to the exchange or substitution of one obligation for another. It is in effect taking a fresh security.

INNS OF COURT. The name given in England to certain voluntary societies which have the exclusive right of calling persons to the English bar. There are four such societies in London, viz., the Inner Temple, the Middle Temple, Lincoln's Inn, and Gray's Inn. Each of these possesses certain smaller inns, which are mere collections of houses or chambers, as Clifford's Inn, New Inn, Furnival's Inn, &c. The four inns are each governed by a committee or board, called the benchers, who are generally Queen's counsel or junior counsel, and chosen, i.e., each new bencher is chosen by the existing benchers. Each inn has also a local habitation, consisting of a large tract of houses or chambers, which are in general occupied exclusively by barristers, sometimes by attorneys, and are a source of great wealth. Each inn is self-governing, and quite distinct from the others, all, however, possessing equal privileges; but latterly, they have joined in imposing certain educational tests for the admission of students. It is entirely in the discretion of an inn of court to admit any particular person as a member, for no member of the public has an absolute right to be called to the bar, there being no mode of compelling the inn to state its reasons for refusal. But, practically, no objection is ever made to the admission of any person of good character. Each inn has also the power of disbaring its members, that is, of withdrawing from them the privilege of practising as counsel; as this right has been rarely exercised, but of late years there have been examples of persons abusing their profession, and indulging in dishonest practices; in such cases, the inn has its own mode of inquiring into the facts and affecting the character of a member, and is not bound to make the investigation public. By this high controlling power over its members, a higher character is supposed to be given to the bar as a body, than if each individual was left to his own devices, unchecked, except by the law. See BARRESTER.

INNSBRUCK (Ger. brücke, a bridge), capital of the Tyrol, is charmingly situated on the Inn, at the height of 1800 feet above sea-level, in the midst of a broad valley, surrounded by mountains ranging from 6000 to 9500 feet high. It consists of an Old Town, a New Town, and five suburbs. The New Town, beautifully laid out, and furnished with broad streets, is united with the older portions of the town by a grand and circumstance bridge across the Inn. The houses are chiefly in the Italian style, four or five stories in height, with flat roofs, the first story arced, and occupied with shops. The most interesting public building is the Franciscan or Court Church, finished in 1563, and containing the tomb of the Emperor Maximilian I., one of the most splendid monuments in Europe. This tomb—which, although constructed at the request of Maximilian, and intended for his burial-place, does not after all contain his remains—consists of a marble sarcophagus supporting the emperor's effigy in bronze, in a kneeling posture, while on both sides of the aisle are rows of monumental bronze figures, 28 in number, representing chiefly the principal ancestors, male and female, of the House of Hapsburg. The other chief buildings are the Museum Ferdinandum, in which are collections of the productions of the Tyrol in art, literature, and natural history; and the university (founded in 1672, and, after several vicissitudes, organised anew in 1825), with faculties of law and philology, and which, in 1857, had 211 students and 15 professors. There are also numerous art collections, many interesting churches, and valuable educational and benevolent institutions. I. carries on important manufactures of woollen cloth, silk, gloves, ribbons, and carved work, as well as a flourishing transit trade. Top. 14,000.

INNUENDO, a part of a pleading in cases of libel and slander, pointing out what and who was meant by the libellous matter or description.

INOCARPS (I. edulis), the Mape or Rota of the South Sea Islands, is a tree important to their inhabitants for its fruit, a nut covered with a thin fibrous husk, which supplies a considerable part of their food, and is sometimes called the South Sea Island chestnut. The fruit is pulled in a green state, and roasted. The tree is a very beautiful one, of stately growth and fine foliage; the leaves oblong, six or eight inches long, evergreen, but of delicate texture. It is one of those which, as they advance in age, instead of increasing uniformly in thickness, throw out buttresses to support the trunk. Small projections first appear, extending in nearly straight lines from the root to the branches, which finally become like so many planks covered with bark. The central stem continues for many years perhaps only six or seven inches in diameter, whilst the buttresses, two or three inches thick, extend from it at the bottom two, three, or four feet. These natural planks are used for paddles of canoes and other purposes.

INOCULATION. If the matter of a variolous (or small-pox) pustule, taken after the commencement of the eighth day, be inserted in or beneath the skin, a local inflammation of that part will arise, and a pustule or small abscess will be produced from small-pox, the following phenomena are induced: 1. Local inflammation is set up; 2. At the end of six days there is fever similar to that of small-pox; and 3. After the lapse of three more days, there is a more or less abundant eruption of small-pox. This process is termed inoculation, and the disease thus produced is denominated inoculated small-pox. The disease produced in this artificial manner is much simpler and less dangerous than ordinary small-pox; and as it was an almost certain means of preventing a subsequent attack of the ordinary disease, inoculation was much practised till the discovery (about 1796) of the antivirous power of vaccination. The importance of inoculation was recognised in the East at a very early period. According to Dr. Collinson (Small-pox and Vaccination Historically and Medically Considered, p. 14), the Chinese had practised this process in the 8th c., and the Brahmanas from a very remote antiquity.

* This was the year in which Jenner inoculated his first case (the boy Phipps) with matter taken from the hand of a girl who had been directly infected by the cow. He was aware of the protective efficacy of cow-pox as early as 1770, and mentioned the circumstances in that year to his master, John Hunter.
INOFFICIOUS TESTAMENT—INQUISITION.

Persia, Armenia, and Georgia it was in use, and it is even said to have been employed in Scotland and Wales. It was not, however, till Lady Mary Wortley Montagu wrote her celebrated letter from Adrianople in 1717, that the operation became generally known in this country. In that letter she writes: 'The small-pox, so fatal and so general amongst us, is here entirely harmless, by the invention of engrafting, which is the term they use for inoculation.)

This notion doubtless was first introduced by the Venetians from the East, and was communicated to the Roman Catholic bishops; but when these conquests were again lost, the popes continued to appoint and consecrate the bishops, as a continual protest against the power whose dominion was thus interfered with, and to signify their hope of restitution. The same policy has been pursued with regard to Protestant countries. But in Britain, the assumption of territorial titles being illegal and dangerous, the Roman Catholic bishops actually resident have usually borne titles derived from distant places. Thus, the present bishop in Edinburgh is styled Bishop of Lymra. The Roman Catholic bishops in England were similarly designated from places abroad until 1717, when the papal bulls from their actual seats gave prodigious offence to the Church of England, and led to the passing of the Ecclesiastical Titles Bill, which, however, has been permitted to remain a dead letter.

INQUEST. See CORONER.

INQUISITION, in English Law, is the return or report made by a sheriff or coroner as to the finding of a jury on matters inquired into.

INQUISITION, The, called also the HOLY OFFICE, a tribunal in the Roman Catholic Church for the discovery, repression, and punishment of heresy, unbelief, and other offences against religion. From the very earliest times, and from the natural disease in its several forms, its effects upon the community at large were extremely pernicious, in keeping alive the natural disease, and increasing its spread amongst those who were not protected by inoculation. While one in five or six of those inoculated by the nurses at the hospital had died, the total number of deaths at the Inoculation Hospital was only 3 in 1000; and yet, according to the authority of Heberden, in every thousand deaths within the bills of mortality in the first 30 years of the 18th c., before inoculation was in use, in every four or five, the death was due to small-pox. The deaths from this disease amounted to 95 in 1000 during the last 30 years of the century; so that, notwithstanding the preservative effects of inoculation, in all who were operated on, the total number of deaths from this disease increased in 100 years in the ratio of about 5 to 4. Moore (The History of Small-pox, 1815) states that, at the beginning of the 18th c., about one-fourteenth of the deaths in London and Dublin were due to small-pox; whereas, at the latter end of the same century, the number (notwithstanding, or perhaps rather in consequence of inoculation) had increased to one-tenth; and this immense consumption of human lives was not the total evil, for many survivors were left with the partial or entire loss of sight and with destroyed constitutions. From these remarks, it will be seen that the benefits which were expected from inoculation were far from being realised, and small-pox would have doubtless gone on increasing in its destructive power, if it had not been checked by Jenner's invaluable discovery of Vaccination (q. v.).

INOFFICIOUS TESTAMENT, a will made whereby near relatives have not been provided for by the testator.

INOWRA Claw (called also Jeng Breslan, ‘Young Breslan’), a small town of Prussia, in the government of Posen, is situated on an eminence in a fruitful plain, 26 miles south-south-east of Bromberg. It is an ill-built town; contains many religious edifices; carries on a considerable trade, especially in brewing, distilling; and the manufacture of saltpetre; and has a population of 6000.

IN PARTIBUS INFIDELIUM (Lat., ‘in the regions of the unbelievers’). Titular bishops in the Church of Rome have been styled bishops in partibus infidelium since the 13th century. They are actual bishops who have no diocese, and take their titles from places where there is now no bishop’s see, but where there once was. This practice originated after the Greek schism, and became general in the time of the Crusades. The places conquered by the Italian and Spanish crusaders were furnished with young Catholic bishops; but when these conquests were again lost, the popes continued to appoint and consecrate the bishops, as a continual protest against the power whose dominion was thus interfered with, and to signify their hope of restitution. The same policy has been pursued with regard to Protestant countries. But in Britain, the assumption of territorial titles being illegal and dangerous, the Roman Catholic bishops actually resident have usually borne titles derived from distant places. Thus, the present bishop in Edinburgh is styled Bishop of Lymra. The Roman Catholic bishops in England were similarly designated from places abroad until 1717, when the papal bulls from their actual seats gave prodigious offence to the Church of England, and led to the passing of the Ecclesiastical Titles Bill, which, however, has been permitted to remain a dead letter.

INQUEST. See CORONER.

INQUISITION, in English Law, is the return or report made by a sheriff or coroner as to the finding of a jury on matters inquired into.

INQUISITION, The, called also the HOLY OFFICE, a tribunal in the Roman Catholic Church for the discovery, repression, and punishment of heresy, unbelief, and other offences against religion. From the very earliest times, and from the natural disease in its several forms, its effects upon the community at large were extremely pernicious, in keeping alive the natural disease, and increasing its spread amongst those who were not protected by inoculation. From these remarks, it will be seen that the benefits which were expected from inoculation were far from being realised, and small-pox would doubtless have gone on increasing in its destructive power, if it had not been checked by Jenner's invaluable discovery of Vaccination (q. v.).

INOFFICIOUS TESTAMENT, a will made whereby near relatives have not been provided for by the testator.

INOWRA Claw (called also Jeng Breslan, ‘Young Breslan’), a small town of Prussia, in the government of Posen, is situated on an eminence in a fruitful plain, 26 miles south-south-east of Bromberg. It is an ill-built town; contains many religious edifices; carries on a considerable trade, especially in brewing, distilling; and the manufacture of saltpetre; and has a population of 6000.
Italy, Spain, Germany, and the southern provinces of France. So long, moreover, as this constitution remained, it must be regarded as a strictly papal tribunal. Accordingly, over the French and German inquisition of the following century the popes exercised full authority, receiving appeals against the rigour of local tribunals (Fleury, v. 266), and ceasing, or even depriving, the inquisitor for unsuccessful, of his office. In France, as in Spain, the inquisition was discontinued under Philip the Handsome; and though an attempt was made under Henry II. to revive it against the Huguenots, the effort was unsuccessful. In Germany, on the appearance of the Beghards (see Beghards), in the beginning of the 14th c., the inquisition came into active operation, and inquisitors for Germany were named at intervals by various popes, as Urban V., Gregory XI., Boniface IX., Innocent VIII., down to the Reformation, when it fell into disuse. In England, it was never received, all the proceedings against heresy being reserved to the ordinary tribunals. In Poland, though established in 1327, it had but a brief existence. The history of the times of its introduction and of its discontinuance in the various states of Italy, would carry us beyond the limits of our command.

It is the history of the inquisition as it existed in Spain, French, and their dependencies, that has absorbed almost entirely the whole interest of this painful subject. As an ordinary tribunal similar to those of other countries, it had existed in Spain from an early period. Its functions, however, in the reign of Ferdinand and Isabella, in consequence of the alarms created by the alleged discovery of a plot among the Jews and the conversos, were considerably increased, and it was required to undertake the discovery and to bring to light the iniquity or to conform to Christianity—to overthrow the government, an application was made to the pope, Sixtus IV., to permit its reorganization (1478); but in reviving the tribunal, the crown assumed for itself the right of appointing the inquisitors, and, in truth, of controlling the entire action of the tribunal. From this date forwards, Catholic writers regard the Spanish inquisition as a state tribunal, a character which is recognised by rank, and even in the great anti-papal authority, Llorente; and in dissociating the church generally, and the Roman see itself, from that state tribunal, Catholics refer to the bulls of this pope, Sixtus IV., protesting against it. Notwithstanding this protest, however, the Spanish crown maintained its assumption. Inquisitors were appointed, and in 1483, the tribunal commenced its terrible career, under Thomas de Torquemada. The popes, feeling their protest unsuccessful, were compelled, from considerations of prudence, to tolerate what they were powerless to suppress; but several papal enactments are enumerated by Catholics, the object of which was to control the arbitrary action of the tribunal, and to mitigate the rigour and injustice of its proceedings. Unhappily, these measures were ineffective to control the fanatical activity of the local judges. The number of victims, as stated by Llorente, the popes themselves, and of the inquisition, is indescribably appalling. He affirms that during the sixteen years of Torquemada's tenure of office, nearly 9000 were condemned to the flames. The second head of the inquisition, Diego de Las, in eight years, according to the same writer, put above 1900 to a similar death; and so for the other successive inquisitors-general. But Catholics loudly protest against the credibility of these fearful allegations. It is impossible not to see that whatever was done was not done by a violent and rabid fanaticism; and it is alleged that in his work on the Basque Provinces, he had already proved himself a venal and unpunishing fabricator. Although, therefore, he has made it impossible to improve his accuracy by appealing to the original papal, which he himself destroyed, yet his Catholic critics—as Heide in his Life of Cardinal Ximenes—have produced from his own work many examples of contradictory and exaggerated statements; Prescott, in his Ferdinand, 1416-1516, p. 479, states that many similar instances; Banke does not hesitate (Peters und Völker der Süd. Europa, i. 242) to impeach his honesty; and Prescott pronounces his 'compositions greatly exaggerated,' and his histories most improbable (p. 468). Still, with all the declensions which it is possible to make, the working of the inquisition in Spain and its dependencies even in the New World, involves an amount of cruelty which it is impossible to contemplate without horror. When it was attempted to introduce it into Naples, Pope Paul III., in 1546, exhorted the Neapolitans to resist its introduction, because it was excessively severe, and refused to moderate its rigour by the example of the Roman tribunal (Llorente, ii. 147). Pius IV., in 1563, addressed a similar exhortation on the same ground to the Milanese (ibid. ii. 257); and even the most bigoted Catholics unanimously confess and repudiate the practice of reviving it under the cloak of a despised religion by assuming its semblance and its name.

The procedure of the inquisition deserves a brief notice. The party, if suspected of heresy, or denounced as guilty, was liable to be arrested and detained in prison, only to be brought to trial when it might seem fit to his judges. The proceedings were conducted secretly. He was not confronted with his accusers, nor were their names used; and he could not be required to make a declaration of an accomplice was admissible, and the accused himself was liable to be put to the torture in order to extort a confession of his guilt. The punishments to which, if found guilty, he was liable, were death by fire, as exemplified in the terrible Anida (q.v.), or on the scaffold, imprisonment in the galleys for life or for a limited period, forfeiture of property, civil infamy, and in minor cases, retraction and public penance. This form of procedure is strangely rare; and it is fair to recollect that some of the usages were but the ordinary procedures in all the courts of the age, whether civil or ecclesiastical.

The Spanish inquisition abated in the latter part of the 17th century. In the reign of Charles III., it was forbidden to punish capitally without the royal warrant; and in 1770, the royal authority was required as a condition even for an arrest. From 1808, under King Joseph Beauart, the inquisition was suppressed until the Restoration; it was again suppressed on the establishment of the constitution in 1820; but it was partially restored in 1825; nor was it till 1833 that it was finally abolished in Spain, its property being applied to the liquidation of the national debt.

The inquisition was established in Portugal in 1577, and its jurisdiction was extended to the Bentinck, in which trying the inquisition's processes, however, was much mitigated in the 18th c., and under John VI. it fell altogether into disuse.

The inquisition in Rome and the Papal States never ceased, from the time of its establishment, to exercise a severe and watchful control over heresy, or the suspicion of heresy, which offence was punished by imprisonment and civil disabilities, as well as by canonical excommunication. For these, the
of the intellectual powers; accompanied also by errors connected with the special senses.

AFFECTIONS OF PROPENSITIES.—Dipsomania, uncontrollable craving for stimulants. Homidal Mania, impulsive desire to destroy life. Kleptomania, uncontrollable desire to acquire.

This catalogue is not intended to be exhaustive. The departures from health will correspond not merely with the primitive mental powers and instincts, but with the human sensations of these, and with such complications as may result from hereditary predispositions, innate peculiarities, education, and habit.—Dr Combe On De Formation, Copland's Dictionary, &c. Insanity.

For the diagnosis and treatment of the insane, see LUNATIC ASYLUM.

INScriptions, a term applied to all writings engraved or written on objects or monuments not of the class of books, principally on haril materials, inscriptions on walls or doors, and on the whole series of table-stones. The inscriptions are a class of documents of the highest interest and importance to history and philology, and a consideration of them embraces the whole scope of history, language, and art. The oldest (excepting those of China) are probably the inscriptions found in the Pyramids (see PYRAMIDS), of about 2000 B.C.; to which succeed those of Assyria and Babylonia, reaching nearly as high an antiquity (see Cuneiform Characters), which are succeeded by the Persian and Median, 550 B.C., and along with which prevailed the Phoenician, probably about 700 B.C. (see PHENICIA); which were in their turn succeeded by the Greek, between 500 and 600 B.C., or even earlier, with which were succeeded the Etruscan and Roman, in 400—300 B.C., and continued through the middle ages in Europe to the present day. See PALEOGRAPHY.

In the East, the oldest inscriptions are those of China, which are inscribed on large stones or slabs, called steles, and on the walls of many of the human mind have led to the belief, that many degrees of feebleness of the faculties, many forms of eccentricity and extravagance, and many defects in the will and moral sentiments, which were formerly regarded as criminal and wickedness, but which do not involve such depravity, may be classed under the same designation. Very recently, the interpretation of insanity has been greatly widened, and now includes various degrees of moral perversion, morbid habits, and sudden impulses, such as dipsomania and homicidal mania. The great divisions of this class of diseases into mania, melancholia, and imbecility, remain popularly very much the same as they were 2000 years ago. While this fact may indicate that such a classification has a foundation in nature, it has, unfortunately, tended to render the treatment, or rather the maltreatment, of the insane as stationary as the view of the character of the human mind by those that labour. The following arrangement may serve to explain what insanity is, as well as what it appears to be.

AFFECTIONS OF THE INTELLECTUAL POWERS.—Idiocy, the non-development of one or more faculties. Imbecility, the imperfect development of one or more faculties. Futility, or Dementia, the depravation by disease, or age, or otherwise, of powers which have been developed. Mania, with delusion, excitement, and irregular action of all, but especially...
INSECTIVORA—INSECTS.

other objects of ancient art, on wax tablets or papyllaria, and the scrawls discovered on the walls of public and private edifices, as at Pompeii and elsewhere, will be seen under ALPHABET; that of the different languages and the mode of deciphering, under their respective heads. Those found upon coins will be mentioned in NUMISMATICS. The most remarkable inscriptions are the trilingual inscription of Rosetta, that of Shalmanazar on the obelisk of Nimrud, and the cylinder of Sennacherib; the trilingual inscription of Darins L. on the rock at Behistun; the Greek inscription of the soldiers of Xammeticyns at Tbecbhden; and of the bronze helmet shaped by Hero I. to the Olympian Jupiter; the inscription on the collar of the Cyprian king Asmumazer; the Etruscan inscription called the Eugubine Tables; that of Mummint, the conqueror of Corinth, at Rome, and the will of Augustus at Ancyra; the inscription of the Ethiopian monarch Silo; the old monument of Yu, and the inscription of Se-gan-fu, recording the arrival of Christianity in China (531 a. c.); the inscriptions of Chandra-gupta and Asoka. The study of these inscriptions is so difficult, that it has formed a special branch of scholarship, such as decipherment for which of those which has been lost, or epigraphy for the deciphering of the inscriptions of different localities, and general ones, have been made of those in the same languages as Assyrian, Greek, Etruscan, Latin, and Arabic. The study of these inscriptions has been pressed forward by such scholars as Gruter, Mommsen, Bockh, Franz, Orellius, Momm- tori, Novus Theaurus (4to, 1739); Kiiellman, Spec. Epigraph. (1841); Mommsen, Inscript. Neapoli. (fo. 1832); Bockh and Franz, Corpus Inscript. Grce. (fo. 1829,—1831); Osan. Syllab. (1822); Leoparn, Inscri. Umbr. et Osr. (1841); General Script. Ling. Pharn. (1837); Garucci, Graffiti (1856).

INSECTIVORA (Lat. insect-eating), in Cuvier's system of zoology, one of the divisions of the mammalian order Carnaria (q. v.). None of the I. are of large size; most of them are small timid creatures, generally social in their habits and useful in the economy of nature chiefly in preventing the undue increase of worm and insect tribes. Although many of them are not exclusively insectivorous, all of them have the summit of the molar teeth beset with small conical tubercles, for the purpose of breaking up the hard coverings of insect prey. Their dentition is otherwise very different in the different families. Their legs are short. They all place the whole sole of the foot on the ground. The snout is generally elongated. The families of Talpidae (Moles, &c.), Soricides (Shrews, &c.), Erinaceidea (Hedgehogs, &c.), and Tupidae (Bankrings) are referred to insectivora. The I., although in some respects very different from the Chiroptera, exhibit an affinity to them in others.

INSECTS (insecta), one of the classes of Articulata (q. v.), or Articulated Animals, of the division having articulated members. All the Articulata having articulated members were included by Linneus in the class of I.; but the Crustacians are now separated from it and afterwards the Myriapoda. See these heads. This restricted application of the term I. corresponds more nearly with its popular use, and so well agrees with its derivation, that it may be regarded as one of the most appropriate names employed in natural history. It is from a Latin word, signifying cut into; a derivation exactly answering to that of the Greek entoma, from which the science having insects for its food is called Entomology. Insects, a natural and extremely well defined class of organised beings, are remarkable, in their mature or perfect state, for the division of their bodies into three very distinct portions—the head, thorax, and abdomen. The abdomen in particular, disportioned, has the slenderness to which the body is there reduced cannot be contemplated without admiration.

The body of an insect, as of all the other Articulata, is composed of a certain number of segments. None of these forms the head; or, if the head ought to be regarded as really composed of several rings, modified and condensed together, as the skull of vertebrate animals is formed of modified vertebrae, yet no distinction of rings appears. The eyes, the antennae, and the organs of the mouth, are the most conspicuous organs connected with the head.

The thorax is formed of three rings, closely combined, but easily distinguishable. The first is the prothorax; the second, the mesothorax; and the third, the metathorax (Gr. pro, before; mesos, middle; and meta, after). Of these rings, one or another is often remarkably developed. The legs and wings are attached to the thorax; and the first pair of wings, as in the grasshopper, is attached to the prothorax; the second, to the mesothorax; and the third, to the metathorax. The first pair of wings is attached to the mesothorax; the second, to the metathorax. The first pair of wings is connected with the mesothorax; the second, with the metathorax. The first and second pair of wings is occupied by two small organs—little threads, terminated by a knob—called balancers (halteres), the use of which is not well known.

The abdomen consists of nine segments, or of fewer; as some are often obliterated, or modified, to form various appendages. It contains the principal viscera. In it, the sexual organs are situated. The wings of the abdomen are much more separate and movable than those of the head. The terminal rings of the females of some groups form an ovipositor, which is sometimes capable of being employed as a borer, to make a place for the eggs in the animal vegetable organism destined to receive them, and which in wasps and bees is replaced by a sting.

The nervous system of I., in all their stages of existence, exhibits the general characters noticed in the Aritculata (q. v.). There is a brain, or ganglion of the head, from which arise the nerves of the eyes, antennae, and mouth. The rings of which the body of an insect is composed appear most distinctly in the external covering. This is in most parts hard, but more or less flexible, of a horn-like substance, chiefly composed of Chitin (q. v.). The external covering of insects is the principal framework of their bodies, and to it the muscles are attached. The external covering of each ring is more or less dissected into two parts—a dorsal and a ventral—the connection at the sides being effected by a softer and more flexible membrane, a still softer membrane connecting the rings of the abdomen, so as to allow considerable freedom of motion; whilst between the rings are minute pores called stigmata or spiracles, by which air is admitted to the trachea or air-tubes (q. v.), the organs of respiration.

Insects require neither by means of lungs nor of
INSECTS.

gills, and the blood is not brought to a particular part of the body for aeration, as by circulation in vertebrate and many invertebrate animals, but the air which enters by the breathing-pores is conveyed by tubes to all parts of the body, and even through the delicate structure of the wings, so that the whole frame is rendered more light by the very means employed to maintain and increase muscular energy. Respiration is extremely active in insects; they consume a great quantity of oxygen in proportion to their size, and they display, in general, an extraordinary degree of activity and muscular energy. The flight of very many kinds is far more rapid in proportion to their size than that of birds; others display a similar superiority of powers in running, swimming, or digging and burrowing; whilst the leaping of many, as fleas and grass-hoppers, and the springing of others, as cheesepickers, prodigiously exceeds anything of which any vertebrate animal is capable. The respiration of aquatic insects takes place in the same manner as that of other insects, and they come to the surface of the water for fresh supplies of air. The blood of L. is thin and colourless. It is not everywhere enclosed in vessels, but is freely diffused in interstices between the muscles and other organs, and in the visceral cavity. It contains globules or corpuscles of determinate shape. How far the dorsal vessel (see ARTICULAT) should be regarded as a heart, is not fully determined; but by its contractions and dilatations, a constant motion of the blood is maintained.

The members of L. have generally a structure analogous to that of the trunk, in being composed of articulations, the hard and solid part of which is the external covering. This appears very perfectly in the legs, the antenna, and the palpi, but not in the wings.

The legs of L. consist of two principal parts, the thigh (femur) and shank (tibia), with two smaller articulations, the coron and trochant, interposed between the body and the thigh, and at the extremity of the shank, a set of three, four, or five small articulations, called the tarsus. The last segment of the tarsus in terrestrial insects is generally terminated by a pair of hooks or little claws; and many dipterous insects, as the House-fly (q.v.), haveicus and suckers for taking hold of smooth surfaces.

The wings of L. are often very large in proportion to the size of the body, and the rings of the thorax are soldered together, and supported by supplementary pieces, to give firm support to them, and to the powerful muscles necessary for their action. The hard covering of the body of an insect consists, like the skin of vertebrate animals, of three layers, and the membranes of the wings are filmy expansions of the outermost of these, the epidermis. The ria or nervation in the wings of L. are tubes, of which one of the uses is the conveyance of air currents to the extremities of the wings. The forms of the wings are very various; some of the more important diversities being characteristic of different orders. The bodies of L. are often very much covered with hairs, which are often very long and thick in proportion to the size of the animal, and on the wings of butterflies and other Lepidoptera are flattened and expanded so as to form scales (see scales). The antennae are usually so long by reason of very fine parallel striae, with which they are marked, displaying an admirable iridescence or reflection of evanescent prismatic colours in changing liglit. The first pair of wings in coleoptera (q.v.); however, is represented by a hard chitinous elytra (Gr. coverings), or wing-covers. Orthoptera have softer leathery or parchment-like elytra.

Insects feed on very different kinds of food; some prey on other L., some devour animal, and some vegetable substances, some suck the juices of animals, some the juices of plants or the honey of their flowers. The structure of the mouth varies accordingly, and the digestive organs also vary. The mouth is generally a complete bag of sucking, cutting, and tearing, or merely for sucking, or it is adapted partially for both of these purposes. The parts of a mandibulate mouth are figured in the article Coleoptera, and are an upper lip (labrum) and an under lip (labium), moving vertically; and an upper pair of jaws or mandibles (mandibular) and a lower pair of jaws (maxiller), moving horizontally. The upper and under lip meet when the mouth is shut. Both are as hard as the jaws. The lower lip is sometimes regarded as consisting of two parts, called the chin (mentum), and the tongue (lingue), which is more membranous and fleshy, and reposes on the inside of the chin. The upper jaws or mandibles are usually powerful, and often so finely toothed and hooked, sometimes furnished with cutting edges like sharp scissors, and sometimes adapted for bruising and grinding. They are also the instruments which bees and other L. use for their wonderful operations of cutting, tearing, building, plastering, &c. The lower jaws or maxillae are generally less powerful. In some L., in which the mandibles are enlarged into great organs of prehension, the maxille alone serve for the ordinary use of jaws in eating. To the maxillae and the lower lip are attached organs called palpi or feelers, consisting of a number of minute articulations, supposed to be delicate organs of touch connected with the purpose of an insinuation, and distinguished as maxillary palpi and labial palpi.

The mouths of mandibulate L. are sometimes called perfect, and those which exhibit a different character, imperfect. The terms, however, are improper—each kind is perfect, according to the purposes for which it is to be used. Yet a correspondence of structure may be traced, so that the parts of the mandibulate mouth may be recognised under various and very remarkable modifications.
in the mouths of I., which live by suction. Thus the filaments which form the proboscis of butterflies are the maxille excessively lengthened, and the cutting parts of the mouth of the flea are the mandibles and maxillae. The proboscis of flies represents the lower lip.

The alimentary canal of I. is usually more or less convoluted. Between the mouth and the proper digestive stomach, it sometimes exhibits a crop (honey-bag of bees) in I. which live by suction, and this is often called a dilatation of the liver part of the gut or a lateral vesicle; sometimes a gizzard, with muscular walls, often armed with horny pieces, for triturating of food. The stomach is of a very elongated form. The liver is represented by long slender bile-tubes, four or more in number, which wind around the intestine, and pour their secretion into it, where it originates from the stomach. The salivary glands are generally similar tubes.

Section of the Eye of a Cockchafer (highly magnified):

A. section: a. optic ganglion, into which the optic nerve swells; b. nerves arising from its surface, and proceeding to the general retina; c. general retina; d. layer of pigment, in front of the general retina; e. optic nerves of the individual eyes which form the compound eye. B. A group of these, much magnified: f. bulb of optic nerve; g. layer of pigment; h. vitreous humour; i. cornea.

The eyes of I. are of two kinds—simple or stigmatic, and compound or composite. See Eye. Some I. have only simple eyes (ocelli), some have only compound eyes; but the greater number have two large compound eyes on the sides of the head, and three small simple eyes between them. Compound eyes occur in I. only in their mature or perfect state; the eyes of larvae are simple.

The Antennae (q.v.) are generally regarded as organs of touch. They are attached to the head, in front of the eyes, and are always present, and always two in number. They exhibit a vast variety of different forms, some of which are figured in the following cut. I. make much use of their antennae to investigate surrounding objects by contact, although, if this is their sole use, it is not very easy to assign any probable reason for some of their forms; but there is not much plausibility in the conjectures which assign to them a part in the exercise of the senses of hearing and smell, although these senses and taste are evidently enjoyed by I., or at least by many I. in great perfection, and their particular seat and organs are not well ascertained. The sense of smell appears to be of great importance to I. in guiding them to their food. The sexes are distinct in all I., and very remarkable differences are often exhibited by the males and females of the same species, in size, colour, and the form and structure of parts that have no immediate connection with the reproductive system. What are called neuters in some tribes are imperfectly developed females. The connection of the sexes takes place only once in the lives of I., and a remarkable provision is made in the female for the consequent fertilisation of eggs, that in some, as bees, continue for a long time afterwards to be successively developed.

Insects are generally omnivorous; a few are ovoviviparous. The Aedes afford an instance of what has been called the Alternation of Generations. The greater number of I. take no care of their eggs after depositing them, and many themselves pass out of existence before the eggs are hatched; the chief part of the lives of I. being generally spent in their immature states, and their brief existence in a perfect state serving mainly for the propagation of their species. Thus many insect tribes disappear entirely on the approach of winter, their eggs awaiting the warmth of spring or summer to be hatched. The case is very different, however, with bees, ants, earwigs, and some others, which carefully tend and rear their young. The number of eggs laid by I. is very various, but often very great. The flea, indeed, only lays about twelve, and many ditterous and coleopterous insects about fifty; but the silkworm produces from 500 to 2000; a single queen bee is supposed to lay 40,000 or 30,000 in a season, and the female termite or white ant, laying about sixty eggs in a minute, and for a period of very considerable though unknown duration, exceeds as to the number of her eggs any other known animal in the world.

The eggs of I. are generally white, yellow, or green; they are of various shapes—round, cylindrical, conical, lenticular, &c.; they are sometimes smooth, sometimes beautifully sculptured.

The stage of development at which I. come forth from the egg is very different in different tribes; in some, they appear as footless worms; in others, they have rudimentary feet, but still with very little power of locomotion; in others, besides little claws representing the six feet of the perfect insect, there are on the abdominal segments of the worm-like body fleshy tubercles serving as feet; in others still, the legs are well developed, and the insect, on issuing from the egg, differs little from the perfect insect, except in the want of wings; whilst, finally, in a comparatively small number (lice, &c.), there is no obvious difference except in size. Similar differences of the degree of development appear in the mouth, eyes, and other organs. Hence the subsequent changes by which the mature state is reached are very different in degree; and I. being primarily divided into those which undergo

Various Forms of Antennae.

(Copied from Ray's Animal Physiology.)
INSECTS.

and those which do not undergo metamorphosis, some of the former are commonly spoken of as undergoing complete, and others incomplete metamorphosis. In the first state of insect life, the insect is called a Larva (q.v.). Grubs, caterpillars, and maggots are the larvae of different orders of insects. From this state it passes into that of a Pupa (q.v.), or nymph—a chrysalis or auricle is the pupa of a lepidopterous insect—and finally it becomes an imago, or perfect insect. The transformations of I. have always been regarded with great admiration. A worm, inhabiting a muddy pool, becomes a winged creature that sports in the air. A crawling caterpillar, that ravenously devours some kind of herb- age with its horny jaws, eating vastly more in proportion to its size than an ox, is converted into a splendid butterfly, flitting from flower to flower, and feeding only on nectaraceous juices. The intermediate or pupa state only adds to the wonder. The caterpillar, after several moltings, or changes of skin, and when it has attained its utmost size, ceases from eating, perhaps fixes itself under a leaf, becomes incased in a horny covering, as in a second egg, and, becoming a kind of chrysalis, metamorphoses, or a butterfly. Many larvae, also, when about to change into the pupal state, spin Cocoonas (q.v.), in which they envelop themselves, by means of spinnerets on the under lip, through which a viscous secretion passes in fine threads that harden into silk. But whilst the pupae of many I. are motionless, or nearly so, and eat no food whatever, the pupae of other I. as dragon-flies, are active and ravenous. The ichneumon wasp, for instance, often differs little from the larval state, except in the possession of wings, or from the perfect state, except in the wings being merely rudimentary and still unfit for flight.

An opinion at one time prevailed, that the successive envelopes of the larva were all contained from the beginning within the first, within them the covering of the pupa, and within it the perfect insect. This extraordinary fancy has given place to the belief, established on sufficient observation, that the envelopes which the growing larva successively casts off, are merely a hard, thick, extra- vascular and unextensible epidermis; that the jaws, claws, etc., of the larva, with which it parts when it leaves the last envelope, which is the form of complete metamorphosis, are connected with the epidermis; and that the covering of the pupa is a new secretion. Discoveries, however, do not render less marvellous, but only more admirable, the changes which take place. Of these, some of the most important are in the organs of the mouth, the digestive organs, and the nervous system.

It is not certain that any insect has a voice or cry, although the origin of the sounds produced by some of them, as the plaintive, squeaking note of the death's-head moth, is not known. The sounds of which we do know the origin are not produced by the mouth or throat. See Grasshopper, Death-watch, and Cicada. The humming or buzzing of I. during flight has been commonly ascribed to the extremely rapid vibrations of their wings. Burmeister, however, supposes it to be produced by the vibratory laminae in the respiratory tubes of the insect, uncorrected by the forcible emission of air during the violent muscular action necessary for flight.

Insects are all animals of small size, and many of them are of striped, speckled, or spotted color, and I. of all sizes abound in warm far more than in cold climates. The I. of the polar regions are comparatively few, and are to be seen only during summer; those of them whose whole existence is not comprised within a single year spending the winter, as very many I. of temperate climates also do, in a state of torpidity. All I. are very fond of heat, and many which do not become completely torpid in cold weather, become partially so. It is only in warm weather that I. display their greatest activity. As to their geographical distribution, I. are found in all countries, to the utmost alpine and polar limits of vegetable life. Many kinds are peculiar to partic- ular climates or countries. The Archipelage and of Australia, like their other natural productions, are generally very different from those of other parts of the world. The I. of elevated mountainous regions within the tropics generally resemble those of the temperate and frigid zones, but are seldom the same. The multi- tude of species of I. is very great. The species of coleopterous I. alone, or beetles, are more numerous than all those of vertebrated animals together.

A few I. are important for their usefulness to man, and a greater number for the injuries which they inflict. Of the former, bees and silkworms deserve to be mentioned, the former being the useful cochin elucid and cantharies or blistering-flies. There are a few others to which we are indebted for substances useful in medicine and the arts, as kermes, lac, galls, &c. Of the injuries inflicted by I., the most serious are those caused by the destruction of herbage and crops, as by the ravages of locusts, of some kinds of caterpillars, and of numerous tribes of coleopterous and dipterous insects. See Aphids, Taxina, &c.

The primary division of I. into those which do not and those which do undergo metamorphosis (Amelobola and Metabolia of Leach), has been already noticed. The former are divided into the orders Thysanura (q.v.) and Parasita (q.v.) or Anoplura, and are all included in the order Apera (see Arthrota L I.) or wingless I. of Linnaeus. The insects undergoing metamorphosis, which are far more numerous, are divided into two great groups, Mandibulata and Hauostellata, the former having the mouth fitted for mastication, the latter for suction. The Mandibulata form the universally recognised orders Coleoptera, Orthoptera, including Diptera of some entomologists, Neuroptera, and Hymenoptera. The Hauostellata, or Hem- iptera, including Homoptera of some, Lepidoptera, Strepsiptera, Diptera, and Suctoria (Aphaniptera of some). See these heads.

Fossil Insects. Several causes conspire to make the remains of I. in the stratified rocks comparatively rare, such as their possession of the power of flight, their soft and speedily decomposing bodies, and the extent to which they are preyed upon by other animals. That they were abundant during some periods is, however, very evident. In the Lower Lias, several bands of limestone occur, which, from the abundance of insect remains con- tained in them, have been called 'insect limestones.' They are crowded with the wing-cases of several genera of Coleoptera, and almost entire, are frequently found. The strongly nerved wings of some Neuroptera are beautifully perfect. In the Eocene strata, at Aswan, a considerable thickness of limestone is found entirely of the insect cases of the aquatic larva of a neuropteron insect. Amber from Tertiary strata often abounds in I., captured and enclosed while this petrified gum was in its primitive fluid condition; and after the gum was permanent in the transparent stone, with every minute detail of structure beautifully preserved. The oldest strata in which insect remains have been observed belong to the Carboniferous period.
The remains consist of fragments of Neuroptera, Orthoptera, and Coleoptera.

The Lower Lias I. belong to various orders; they are generally of a small size apparently indicating a temperate climate. In the Upper Lias, they are not infrequent; a few specimens have been found in the Oolite proper; and in the Wealden, both land and water forms occur. None have been noticed as yet in the deep sea rocks of the Cretaceous period, but in the newer Tertiary strata they are common, especially in the amber from the lignite beds of Germany, and in the cavern deposits. It is worthy of remark that no new forms have been observed; all are either referred to living genera, or placed in new yet nearly allied genera.

Insessores (Lat. perchers), or Perching Birds, an order of Birds called Passerina (sparrowlike) Birds by Cuvier. In respect of the number of species which it contains, it is by far the largest order of the whole class of Birds. Cuvier says: 'Its character seems at first sight purely negative, for it embraces all those birds which are neither swimmers, waders, climbers, rapacious, nor gallinaceous. Nevertheless, by comparing them, a very great mutual resemblance of structure becomes perceptible, and characteristic being found in the structure of the feet, which are particularly adapted for perching on the branches of trees, and have three toes before and one behind, the hind toe on the same level with the others. The legs are neither very long nor very strong; nor are the claws in general very long or very sharp. The wings are often long, and the power of flight very considerable, but this is not always the case. The neck is not long. The bill exhibits many varieties in length, thickness, &c., being very short and thick in some, very slender in others, but never exhibits the characteristic peculiarities of the accipitrine beak, although there is an approach to them in the shrikes, which are a connecting link between the two orders. The I. with short strong beaks are principally granivorous, those with slender beaks insectivorous; but very many adapt themselves almost indifferent to both kinds of food. Some feed on pulpy fruits, some on vegetable juices; some chiefly on carrion. The stomach is a muscular gizzard. To the order I. belong the singing-birds, and throughout the whole order a variously complicated structure of the lower jaw prevails. The I. of Europe and America, that of the trees in most of them seem to endure only for a single season. They generally build interwoven nests, and lay numerous eggs. The young are always naked and blind on coming forth from the egg. — The I. are divided into four great tribes or sections, Dentirostrae, Conirostrae, Tenirostrae, and Fistrostrae. See these heads.

Insolvency, or Bankruptcy, is the state of a person declared to be unable to pay his debts. Insolvency is a term which in England has long been confined to the case of a non-trader who was unable to pay his debts. All who were traders (a term which was not always easily defined) were said, in the same circumstances, to be, not insolvent, but bankrupt. Different courts, called the Bankrupt and Insolvency Courts, were applicable respectively to these two great divisions of mankind, traders and non-traders, and the chief points of difference in the procedure were these. In the case of traders, the Court of Bankruptcy was the court to which they or their creditors applied for its summary intervention. In the latter, whenever a trader was unable to pay his debts—certain tests of which inability, called acts of bankruptcy, were assumed as inaliable symptoms—on the application of a creditor, took forcible possession of his property or his assets of every kind and denomination, converted these into money, and distributed the produce impartially among the creditors, according to his original or the court expense of the credit. In the course of doing this, the court required the bankrupt to state all the property he had, where it was, and to give explanations as to what had been lately lost; and it was a crime for him to conceal the production and discovery of which he was bound to the prejudice of the impartial distribution. The creditors also came in and proved their debts against his estate, thereby shewing their title to share in it. In this way the debtor was entirely stripped of everything (with a few tradiing exceptions) which he had, and which was salable; and, on the other hand, he received a certificate which entirely cleared him of the incurrence of his past debts for ever—freed him not only from imprisonment, but even from the liability to pay more in future, should he afterwards become rich; and he could thus begin the world anew.

On the other hand, the non-traders, who consisted of persons, gentle or professional men, gentlemen at large, and nondescripts of every degree who were not traders, fell under the care of the Insolvent Court. These non-traders petitioned the court voluntarily, instead of their creditors doing so, as was the case in the Bankrupt Court. The Insolvent Court of course put off this application till the last, when they were in prison, though they might also petition before any creditor put them in prison. The sole condition on which the Insolvent Court granted their discharge, was, that they should not only give up all their property, but state fully all the debts and liabilities they had incurred. If they did this satisfactorily, the court relieved them from imprisonment, which was almost equivalent to making up their debts. It was their duty to make up all that they could of their debts; and if they did this, and afterward had a contingency, however, seldom happened, and, moreover, when it did happen, considerable leniency was shown to the debtor, so that practically, both in Henry VIII. and in bankruptcy, the debtor was more or less whitewashed, and was at least saved from imprisonment.

Recent changes have been made in the English law on this subject, and more are impending. It was declared to abolish the distinction between traders and non-traders, to fuse the enactments together, and make all insolvent persons, whether they were traders or non-traders, subject to the same law, as is the case in Scotland, and as has been the case in America since 1841. This intention has not yet, however (1862), been entirely carried into effect in England, though a great deal has been done towards that consummation. The distinction is, therefore, still kept up for several purposes, and must be admitted that there is a difference in the nature of things between the two cases.

The Bankruptcy laws date from the time of Henry VIII., and the insolvency laws from the time of Elizabeth. The distinction as above explained has always been kept up between them till the late statute 24 and 25 Vict. c. 134, passed in 1861. By that statute, the Insolvent Court was abolished. The court now administering the branch of the law is called the Court of Bankruptcy, which, as far as the London district is concerned, sits in Basinghall Street, City. The London district includes all the counties near Middlesex within an area of about 100 miles. The rest of England is divided into
INSOLVENCY.

separate districts, such as Birmingham, Leeds, Manchester, Liverpool, Bristol, Exeter, Newcastle-upon-Tyne. The judges are called Commissioners, and bare salaries of £2900 and £1800. The county court judges, except in the metropolis, also have all the powers of commissioners. The other chief officers are registrars, with salaries of £1000, £1200, £1400:—a taxing-master with a salary of £1400, and an accountant in bankruptcy with a salary of £1500. The salaries of these officers must be paid by the Board of Trade, and if they do not amount to £1200, £1000, £800, in whom the estate of the bankrupt immediately vests, and who therefore, with the creditors' assignees, manage the bankrupt estate, and convert it or, if any meaning of bankruptcy are a sort of bailiffs, who take manual possession of the bankrupt's premises and goods. Their profits from fees, &c., before the recent act passed, were enormous, and their salaries are now reduced to £600 and £400.

The tests of bankruptcy, or rather the acts done by a trader which make him liable to be proceeded against as a bankrupt, are technically called acts of bankruptcy. These are: departing the realm—i.e., leaving the country; it is to have notice of his dwelling-house—keeping (himself prisoner in) house—suffering himself to be arrested or taken to prison for debt—or allowing his goods to be taken in execution for debt—executing a fraudulent grant, gift, or conveyance of his lands or goods. If a trader execute a conveyance of his whole property to a trustee for the benefit of his creditors, this will be treated as an act of bankruptcy, if any creditor petition in three months to make him a bankrupt. So, after a petition has been presented, the paying or giving security to any one creditor, so that he shall receive more than the other creditors, is an act of bankruptcy. If any creditor petition in three months to make the trader requiring immediate payment, the Court of Bankruptcy may order this to be filed, and call on the trader, if he do not bond and file dispute the debt, to enter into a bond with sureties to pay it in a given time, and refusal or neglect to attend on or pay this, is an act of bankruptcy. With regard to a non-trader, the acts of bankruptcy are these: if, with intent to defeat or delay his creditors, he depart the realm, or remain abroad, or make a fraudulent conveyance, or the like of his personal estate; but in these cases the court will not declare him bankrupt until it is shown that he has, whether abroad or not, been personally served with notice. A bankrupt must within the time after the bankruptcy, every reasonable effort has been made to effect such personal service; that is to say, to put into his hands written notice and full information of what is intended against him. Other acts of bankruptcy, which are applicable to both trader and non-trader alike, are the lying in prison for debt—suffering his goods to be taken for debt—filing a declaration in the Court of Bankruptcy that he is unable to meet his engagements, provided a petition for adjudication of bankruptcy be filed against him within two months thereafter. It thus appears that a person may be made bankrupt either on his own petition or on the petition of any creditor, after one or other of these acts of bankruptcy has been committed.

The mode in which an adjudication in bankruptcy is conducted in England is as follows: The act of bankruptcy, as already explained, must have occurred within three months before the proceeding is commenced. The first step is a petition to the court. This may be presented either by the debtor or a creditor. If, as is most usual, it is presented by a creditor, then such creditor must have a claim of debt amounting to not less than £50; or if the debt of two creditors amount to £70, they may jointly petition; or if the debt of three creditors amount to £100, they may jointly petition. Such debts may be due under mortgages, securities, or liens, and the costs and interest previously due in respect of such debts count as part of the whole debt. If a person in prison for debt is too poor to pay the fees, he will be allowed to present the petition against himself in form papers; and as a monthly return of all debts must be delivered to the Board of Trade, if prisoners remain beyond a limited time—viz, if traders beyond a fortnight, and if non-traders beyond two months—without voluntarily petitioning, the court will compel the non-trader to do so, and deal with them accordingly, including the power of releasing them from prison. On the petition for adjudication of bankruptcy being presented, together with an affidavit of the debt, it is filed in court, and on proof of the trading and act of bankruptcy, the court adjudicates the debtor a bankrupt. The court then appoints an official assignee to take possession of the property and premises. Before the adjudication is advertised in the Gazette, the debtor is personally, or by his agent, sworn in the manner prescribed by law, and there is given to the official assignee an affidavit, with a statement of the debtor's property and debts. The official assignee, with his own costs, prosecutes the petition up to the stage when the creditors choose their assignees, when these costs are repaid to him. Soon after adjudication of bankruptcy, a ten days' notice is given in the Gazette to the creditors to meet and appoint assignees. On this occasion, the creditors must first prove their debts, which they do by their affidavit or oath, together with production of any security or document verifying the debt. All creditors having thus proved whose debt exceeds £10, have power to choose one or more persons as creditors' assignees; but the court has power to reject such choice, if unifit. The creditors may be represented on such occasion by any person who can produce petitioners. Creditors may determine whether such assignee shall give security. The court declares the appointment final. From the moment of their appointment, the whole of the bankrupt's real and personal property of every kind vests in them. They can sell it, and in general do everything which the bankrupt himself could have done. They are accountable to the creditors, and must render quarterly accounts to the official assignee, which accounts must be printed and sent to every creditor. They manage and realise the estate and collect the debts, except those under £10, which the official assignee collects. The court can summon the bankrupt, his wife, and all persons for examination. A sitting is appointed for the last examination of the bankrupt, when he must prepare a statement of the accounts for the satisfaction of the creditors. Meanwhile all creditors who have debts must complete the proof. Every creditor may prove his debt by his own hand or sending through the general post, to the official assignee—or, if the creditors' assignee has been appointed, then to the latter—a statement of such debt, and of the account of any, and a declaration signed by such creditor appended thereto such
INSOLVENCY—INSPECTOR, INSPECTOR-GENERAL.

statement is a true, and complete statement of account, and that the debt is justly due. If the debt is undischarged, and consists of unliquidated damages, then the creditor must be empowere to proceed against the debtor, either before itself or a court of law, to fix the sum. Debts which have been incurred, but are payable at a future time, may also be proved, and so may contingent debts and liabilities. When wages are due to clerks or servants at the time of the bankruptcy, the court may order a sum not exceeding three months' wages, and not exceeding £30, to be paid in cash; and for any surplus that may be due, the clerk or servant must prove and share with the other creditors. If the creditor opposes a particular debt, and shew it is unfounded, the court will expunge it. When all the examinations necessary of the bankrupt have been given through, a day is appointed for considering his discharge. The court allows creditors to oppose this step; and if it appear he had traded with fictitious capital, or had no reasonable expectation of being able to pay the debts he contracted, or if his insolvency was caused by his having accumulated, or unjustifiably extravagant in living, or if he vextationely put his creditors to expense, the court may either refuse or suspend for a time the discharge, or may grant an order of discharge subject to any condition as to future commitments, profits, earnings, or that may afterwards become due, and touching afterwards or property, or may sentence the bankrupt to be imprisoned for any period not exceeding one year. If the discharge is granted, is classification of certificates is awarded, as formerly; but in case of suspension or sentence to imprisonment, the discharge shall simply state such facts and the reasons. The effect of the discharge is to free the bankrupt entirely from all debts capable of being proved under the act. Proven creditors may recover it in their power to determine whether any and what allowance should be made to the bankrupt up to and upon his discharge.

If, after an adjudication of bankruptcy is issued against a debtor, the fourths of the creditors at their first meeting resolve that the estate ought to be wound up under a deed of arrangement, composition, or otherwise, the court, if it appear such composition or arrangement is beneficial to the creditors, is bound to confirm such resolution, and stay the proceedings. So if the debtor enter into a deed with his creditors for winding up his business, it shall be valid and binding on all the creditors if executed within two months, and in value of the creditors above £10, and if the debtor's solicitor attested the same. Such deed is to be registered in the Court of Bankruptcy, and the court has jurisdiction in most respects as regards the carrying out of the deed.

The criminal offences committed by a bankrupt are such as not surrendering himself to the jurisdiction of the court at the time appointed; not making a full discovery of all his property and his dealings with it; concealing or misapplying the property, to confirm such resolution, and stay the proceedings. So if the debtor enter into a deed with his creditors for winding up his business, it shall be valid and binding on all the creditors if executed within two months, and in value of the creditors above £10, and if the debtor's solicitor attested the same. Such deed is to be registered in the Court of Bankruptcy, and the court has jurisdiction in most respects as regards the carrying out of the deed.

In Ireland, bankruptcy is substantially the same process in all its features as in England.

Scott Bankruptcy, or Sequestration, is substantially the same process as that which prevails in England and Ireland; but there are some differences of no small importance, besides the different names given to the steps of the process. Certain acts and conduct of the bankrupt are held to be symptoms of notour bankruptcy, corresponding to what are called in England acts of bankruptcy. The first step is a petition for sequestration, which may be presented by either of the debtors to the same amount as in England. There is no separate court of bankruptcy, but the sheriff of the county, or the Court of Session, has jurisdiction to award sequestration, and the court then appoints a judicial factor to receive, until the creditors elect a trustee, in whom the property vests. The creditors also appoint commissioners to advise with the trustees as to the management of the estate. The duties of the trustee and commissioners are nearly identical with their powers in England, and the commissioners of the creditors fix the trustee's remuneration. The trustee examines the grounds of claim of creditors, there being an appeal to the Lord Advocate if the creditor is bankrupt in arrear, but if bankrupt in a debt, if necessary. On a report from the trustee as to the conduct of the bankrupt, which is not demandable by the bankrupt till five months after the sequestration, the bankrupt petitions for his discharge in the court, or for his discharge, if entitled to his discharge at once; at later dates, if he has the concurrence of a certain number of his creditors, he is also entitled to a discharge; but if the creditors oppose, the court has a discretionary power to refuse, or suspend the discharge, without conditions. In Scotland, there is no distinction, as there was, and still is, for some purposes in England, between traders and non-traders. Another peculiarity of a Scotch sequestration is, that in the case of debtors who are alive, but in case of persons who have died in insolvent circumstances; whereas in England, the only remedy is an administrative suit in the Court of Chancery. In Scotland, there is a process called cesso bonorum, which resembles, in the principle of which is, that the debtor is only relieved from imprisonment, but not from the debt; and where the debtor has transferred to the trustee, and the creditors have to resolve that their debtor shall not have a discharge under the sequestration, but only a decree in a cesso bonorum (q.v.). With regard to the effect of a discharge under a bankruptcy in Scotland, the principal rule is, that whether the bankruptcy is awarded in England, Ireland, or Scotland, all the property of the bankrupt vests in the assignee or trustee, wherever it is situated; and when the bankrupt is discharged, the discharge is thereafter complete and given effect to in all parts of the United Kingdom. Of late years, owing to the belief that it was much easier to be made a bankrupt, and obtain a discharge from debt, in Scotland than in England, various English debtors resorted to Scotland for forty days, to live there, in order that they might be made bankrupt, no doubt thinking that creditors would be less likely to oppose their discharge at that distance; and after their discharge, they returned to England, and pleaded this Scotch bankruptcy, as an answer to all their creditors. But a recent statute has given power to the Scotch courts, in such cases, to refuse the remedy of sequestration to creditors whose debts were hereby contracted in England, and to remit them to their own country.

INSPECTOR, INSPECTOR-GENERAL, terms in military affairs, having a somewhat vague signification. There are inspectors-general of cavalry,
INSPECTORS OF SCHOOLS—INSPIRATION.

infantry, artillery, engineers, militia, and volunteers, whose duties are really those which their names infer—viz., the periodical inspection of the several corps of their respective arms, and the pointing out of deficiencies, the corps being under their command, however, and in the direct supervision of the inspector-general. The inspectors-general of musketry and gunnery instruction are charged with the direct superintendence and ordering of such instruction throughout the army. In the medical departments, the officers of the medical corps constitute the highest grade of surgeons, under the director-general of the whole department; an officer of this rank has charge of the entire medical arrangements of an army or of a large command.

Inspectors are employed in many capacities. Inspectors of volunteers are staff officers charged with the administration, battalions, and organizing into corps d'arme of the detached corps of volunteers in their several districts. Inspectors of musketry superintend the instruction in musketry, as imparted by the regimental instructors, &c.

INSPECTORS OF SCHOOLS. See National Education.

INSPECTORSHIP DEED is a deed executed between an insolvent person and his creditors, whereby they accept a part payment, and allow the insolvent debtor to carry on the business under their supervision, with a view to further payments.

INSPIRATION (literally, breathing into) is applied in theology to denote the action of the divine mind upon the human mind, whereby the latter is both supernaturally informed and qualified to communicate the information received. The term revelation is used more distinctively to express the first part of this action, and inspiration to express the second part. But, in truth, all inspiration, as the word itself bears, implies revelation. There is a necessity for supernatural qualification in the utterance of truth, only where the truth is such as has not been reached by the ordinary exercise of the human faculties, but in some degree at least supernaturally communicated. The prophet or apostle is inspired only as the utterer of knowledge beyond the ordinary reach of human intelligence.

The inspiration of the Scriptures signifies a supernatural qualification or special divine authority in the several books of the Holy Bible. When the theologian asserts any book of the Bible to be inspired, he means that it possesses an authority different from any other book, that it contains truth not merely as any ordinary book may do, but by a special divine impress. It is different from ordinary books, as conveying in a more immediate and direct, and therefore authoritative, manner divine truth. All orthodox theologians may be said to agree in ascribing this special divine character to the Holy Scriptures; but further there is no agreement. The mode of inspiration, the degree and extent of it, are all subjects of dispute. On one side, there are the advocates of plenary inspiration, as it is called; then there are those who advocate various subordinate or partial degrees of inspiration. The advocates of plenary inspiration contend that the whole letter of Scripture is inspired; that its words were immediately dictated by the Holy Spirit, and are the words of God himself. The several writers of Scripture were nothing more than the penmen of the Divine Spirit, under whose control they vibrated as the strings of a harp in the hands of an artist. They were as a piece of mechanism, touched by God himself. Those who maintain this theory, speak, indeed, of the individual and diverse characteristics of the writers, of the Scriptures, but only as one would speak of the different tones which the same artist would produce from one and the same musical instrument.

The differences are not so much in the moral or intellectual individuality of the writers themselves, as in the divine influences with which the Holy Spirit employs them; for, according to that theory, the Divine is all in Scripture, and the human intelligence its mere vehicle or passive instrument. The words of Scripture are no less the words of God than if He were heard to utter them from heaven. It follows from the same theory, that inspiration is essentially intermittent. It is not a higher quality of any soul, but a divine afflatus, seizing the soul at certain moments, and abandoning it at others. While the canonical epistles of St. Paul and St. Peter are to be held inspired, the words of those apostles at other times may not have possessed any special authority. The authenticity of the Scripture which they have delivered, however, is absolute. The inspired or theophanic document is throughout faultless, as the sole work of the Divine Spirit, faultless equally in its form and in its essence, in its spirit and its letter. It admits of no gradation; all is equally divine, and therefore equally accurate, whether it is the words of some ordinary man, or some great truth of the supernatural life, whether it treat of a dogma or of the details of a narrative. As one of its recent supporters writes:

"Every verse of the Bible, every word, every syllable of it, every letter of it, is the direct utterance of the Most High." It follows no less than that what God has thus miraculously written, He must have miraculously preserved. A providential canon is the plain sequence of a plenarily inspired Bible.

In opposition to this theory are various others, all of which impose certain limits upon the perfection of Scripture. Some confine inspiration to all that is directly religious in the Bible, to all that is directly of the character of revelation, leaving out of the question all that belongs to the sphere of science or ordinary history. Others except the form or letter of Scripture, and attribute inspiration only to its spirit, ideas, intellectual and moral value; regarding the first preachers of the Word of God, sometimes with the peculiar privileges of prophets or apostles, and sometimes with their special position as immediate witnesses of the facts of revelation and their singular religious aptitude. Whatever differences may characterize the advocates of these respective views, it is plain that they, one and all, have abandoned the ground of the absolute infallibility of the letter of Scripture.

In a matter of controversy like the present, it is not our function to determine in favour of any particular view, but simply to indicate what the more important opinions are, and the grounds on which they are held. There are those who advocate various degrees of inspiration in the Bible a freedom from all error or imperfection, do so on the ab priori ground of necessity; such infallibility is held to be implied in the very idea of a revelation of the divine will; while those passages which seem inconsistent with the facts of source or of history, or with other parts of the Bible itself, admit, it is maintained, of satisfactory explanation. For such reconciliations of apparent discrepancies our readers are referred to the current commentaries and harmonies. Those theologians, again, who deny the necessity of infallibility, and hold that the inconsistencies referred to 'never have and never can
be satisfacto/y explained away (and their number has been for some time on the increase), argue in the following way: It is plain, first of all, and espe-
cially, that the question is not one to be settled according to any preconception, but according to the evidence of the facts given us in Scripture. The only right idea of inspiration is, as one has said, 'that which we form from our knowledge of the Bible itself. It is a question of attending to the truth, by verifying it in the Bible as such; to see whether the Bible is right or wrong, by examining what it actually is.' All d' a priori arguments are evidently at once inapplicable and danger-
ous on such a subject. The partisans of plenary inspiration maintain that it is necessary, to the
safety of the Word of God. But if an infallible text and an infallible canon be necessary, why not also an infallible interpretation? Without the latter, the two are of no use. A text may be lost by a false or defective commentary of the sacred text. It is plain that the idea of verbal inspiration cannot stop short of the conclusion of an infallible inter-
pretation; and even such a conclusion, which upsets Pre-supposition, denying the right of free inquiry, would not save it; for an infallible commentary would not necessarily insure infallible instruction — all might still be lost by the weakness, ignorance, or defect of the recipient mind. No infalli-
ble text of, or even of, the Bible as such, could insure the infallible reception of the truth, thus trebly guarded. If we would not be caught, then, in this absurd chain of assumption, we must break its first link, and ask, not what is, but what it is.
This view is strongly argued in a recent treatise on inspiration by M. de Presseuse, one of the most distinguished of the French Protestant divines belonging to the school of the Helderian theologians. According to this writer, who may be taken as the representative of a large class of theological thinkers, the Bible is a mass of documents of varying age and varying authenticity; its text has undergone the usual changes attendant on the trans-
mission of historical documents; it is marked by the usual inequalities and varieties of style that we meet with in any other collection of ancient litera-
ture; it presents in many cases peculiar difficulties, differences and even contradictions. The human messenger whose following are only a few of the instances in which such 'imperfections and contradictions' are by themselves.
1. The recital of the temptation in St Matthew and St Luke (the former Matt. iv. 6—8, the vision from the pinnacle of the temple is placed first; in the latter (Luke, iv. 1—10), that from a lofty mountain takes precedence.
2. In Matt. x. 10, Jesus commands his apostles to take for their missionary journey neither scrip, neither two coats, neither shoes, nor yet staffs. In Mark, vi. 8, he commands them to 'take nothing for their journey, save a staff only.'
3. In the narrative of the Passion, as in that of the Resurrection, there are numerous contradictions of detail resting on a fundamental and striking unity. According to Mark, xiv. 72, the cock is represented as crowing on each of the first and second occasions on which Peter denies his Lord. In the accounts given by the other evangelists, the cock only crows upon the third denial (Matt. xxvi. 74; Luke, xxii. 60). The statement of the death of Judas occurs maternally in Matthew and in the Acts of the apostles; what is the case? According to the former, Judas casts down the pieces of silver, and departs and hangs himself; and the chief priests offer-
swards purchase with the price of his guilt the pedlar's field for the burial of strangers, hence called the field of blood. According to the Acts of the Apostles, i. 18, Judas himself is represented as having purchased the field 'with the reward of iniquity'; then as having in some way (not explicitly the same way in both), and from which circumstance the field took its name. In the narratives of the Resurrection, it is well known there are numerous variations; and numer-
ous palpable errors of memory as to historical facts occur. One only is given, among the thousands of Judas,' he translates: 'They art not the least among the princes of Juda.' In many cases, the New Testament writers, while repeating the same story, vary it; among the thousands of Judas, one of them turns them to admirable account: this is especially remarkable in the gospel of St Matthew and the Epistles of St Paul. Thus (ii. iii), St Matthew translates with the Septuagint: 'The voice of one crying in the wilderness.' The former says: 'A voice cries, Make plain in the wilderness the ways of the Lord.' (Isaiah, xi. 3). Compare also Matt. xii. 21 and Isaiah, xiii. 4, also Matt. xv. 8 and Isaiah, xxix. 13. Not in these errors, it is maintained, are of any material consequence so far as the substantial veracity of Scripture is concerned. The very fact that a microscopic criticism can detect no more serious inconsistencies in the Scriptural writers, is rightly held to be one of the most convincing evi-
dences that any text, however genuine, which has been handed down to us, is, in reality, the result of a long and varied process, in which many of the various correctors have contributed, and where the transmission is not to be regarded as a 'direct utterance of the Most High.' Not, therefore, according to these theo-
logians, does not imply the infallibility of the Scriptural text; it is something consistent with scientific, historical, exegetical, and even argumentative errors (witness, to quote no other example, St Paul's allegorical argument about the sons of Abraham, Gal. iv. 22, 25). There is nothing valid, no divine authoritative element, it may be said, that can survive such deductions. If there are such errors in Scripture, why may it not all be
INSTALLATION—INSTINCT.

imperfect or erroneous? The sufficient answer is, that it is not so—that, judged by the very same critical tests of the Animal's such a Book remains an entirely unique book. Every Christian mind recognises in it a higher divine knowledge and authority than in aught else. The divine spirit in Scripture makes itself felt, shines forth in every page of it; and thus in inspiration in the highest sense, the mind of God meeting our minds in Scripture, enlightening, guiding, elevating, purifying them. There is nothing more in reality to be got from any theory than this. An inspired letter, or word, or message is nothing to any one in itself; the meaning is everything. We must understand the word or message. There is no degree of objective authority that can supersede this subjective process of apprehension on our part. There cannot, therefore, be immunity from error, let the symbol or the text be as perfect as possible. It is only to us what we see it to mean; and this meaning, in the case of Scripture, shines with a divine power and splendour such as invests itself in its own divine witness. In such an idea of inspiration, criticism finds nothing inconsistent, nothing impossible, and no higher idea can be well formed of it.

INSTALLATION, in Church Law, means the ceremonial act or process by which a thing is presented and legally conferred in a benefice is formally put into possession of his office, and by which he is fully empowered not only to exercise his functions, but to enjoy its honours and emoluments. It is a ceremonial form, as well as the name, differs among the various dioceses. As 'enthusiasmus' for a bishop, 'induction' for a rector, &c., Installation properly regards the office of a canon or prebendary. The word is also used generally for a formal introduction to any office.

INSTERBURG, a town of Prussia, in the province of East Prussia, is pleasantly situated on the left bank of the Angerap, 15 miles west-north-west of Gumbinnen. It contains a castle, and several educational institutions. Cloth-weaving, tanning, brewing, and distilling, with a trade in corn and linseed, are here carried on. Pop. 11,814. I. had its origin in a castle of the Teutonic Order of Knights, built here at an early period. At the close of the 16th c., it had attained the rank of a town, which increased considerably after the 17th c., about which time a number of Scottish families settled at 1. on account of its trade.

INSTINCT. It has been common to describe the actions of the lower animals as guided by principles different from what obtains in the human constitution. The power of self-preservation is considered as reason in man, and as instinct in the brute; but this contrast does not contain a real opposition. There is much that is common in the instinct of men and animals. When an animal, having found a morsel agreeable to its taste, masti- cate and swallows it, and takes up another of the same, the mental operation is not essentially different from what a human being would go through in the like circumstances. In both instances, we have an example of the exercise of Will, or volition, which operates to promote the pleasures and ward off the pains of the sentient being. The impulse in the living being connected with the term Instinct is what contrasts with experience, education, and acquired knowledge. The original innate tendencies and powers of the mind are to be distinguished from the powers that grow out of the experience of the animal's experience of the world, and its companionship with other living creatures.

There has been a disposition to under-rate the acquired aptitudes of the inferior animals, and to regard their capacity to perform their own work as being purely from their natural or primitive endowments. But in point of fact, men and animals alike possess both instincts and acquisitions; for although in man the preponderance is greatly in favour of the acquired, he, too, must start from something primordial, the basis of the other. To ascertain what is really primitive in the human mind, is an interesting problem both on its own account, and also as throwing light on the still more difficult subject of animal instinct.

In the first place, there are certain actions of importance to the safety and well-being of the individual that are termed Reflex, or Automatic. They seem to be almost out of the sphere of mind proper, as they are performed even unconsciously. Among these are the propulsion of the food along the alimentary canal, sneezing, respiration, &c. In all these, we have important activities, which are essentially inherent in the construction, and are performed as effectually at the beginning of life as at the full maturity of the being.

In the second place, there is a certain original part of human nature, which is the more fully discussed in Locomotion. Thus, there is a natural tendency to alternate the limbs, although the human infant cannot turn this to account at once for the ends of walking, as some of the quadrupeds can. From this alternation, the two sides and faces of the body, and the two sides of the face are especially exempted, and brought under another arrangement equally primitive—namely, concurrence; for it may be noticed that the eyes always move together, and cannot by any effort be prevented from doing so. The conjunction of the two sides of the face is less rigorous; we may acquire the power of opening one eye, and of contorting the features, by making one side act without the other. But all these cases alike illustrate the presence of an original mechanism of the frame, by which the movements are grouped up to a certain point.

In the third place, it may be safely maintained that there is an inherent tendency in all animals to act somehow, or to put forth the energies that they possess, without waiting for the stimulus of their sensations. This Spontaneous Activity is shewn more or less in every creature after rest and nutrition. The dog in the house takes the field without any special aim, in the first instance; they are simply urged on by an inward battery of undischarged power. They soon learn to bring this power into the service of their wants, or to direct it for their preservation and pleasure; but it shews itself at once, and before its effects are known or calculated. Some animals have this tendency in a very high degree. Destitute of any special direction at the outset, it yet prompts to a great many experiments or trials upon things, in the course of which the animal discriminates the suitable from the unsuitable by means of its sensations, and thereby learns to follow up the one and eschew the other. This is the most vital condition in training the requirements of animals, for it enables us to surmise that some of their aptitudes that manifest themselves so early as to appear instinctive, may be, after all, nothing more than very rapid acquisitions, the result of that experimentation prompted by the inborn or spontaneous activity.

Fourthly, in connection with our Emotions, there are certain primitive links of mental state with the course of the animal's bodily manifestations, which constitute the natural language of the feelings understood by the human race. The meaning of the smile, the frown,
the sob, the contortion of pain, is uniform, and therefore instinctive. See Emotion.

Fifthly, the power of will or volition, although it can be shewn to be a growth, must have some primitive and instinctive elements in the constitution to start from. See Will.

Certainly, there must be certain primordial powers of the human intellect. What these are, has been much disputed. Every one must concede the existence of some intellectual forces or faculties, as, for example, Discrimination, the basis of all knowledge; Retentiveness, the faculty of acquiring everything that is acquired; and agreement, or Similarity (see Intellect); but it is contended by one school that we possess not merely powers of receiving knowledge by our contact with the world, and our consciousness of our minds, but actual notions or ideas that cannot be traced to our experience of the material or mental phenomena that we encounter. This is the doctrine of innate ideas, intuitive conceptions, a priori cognitions and judgments, first truths, &c. and it has been upheld both as regards knowledge and as regards practice or duty. Locke's Essay on the Human Understanding contained the first elaborate examination of this doctrine, against which he produced an array of most formidable objections (Book I.). Kant and his school have maintained the a priori view with reference to a certain class of first principles, such as the axioms of mathematicians and the law of causation. Sir John Herschel and Mr. John Stuart Mill are among the most distinguished living advocates of the opposite opinion, which would refer such principles as the mathematical axioms ('things that are equal to the same thing are equal to one another,' &c.) to experience, to any other species of knowledge. See Common Sense.

Seventhly, closely allied to this last controversy, if not a part of it, is the instinctive foundation of belief. The faculty of believing must be pronounced a genuine instinct, for although experience supplies us with natural conjunctions, as that 'water drowns,' 'fire burns,' 'the stars are distant,' that peculiar energy called belief, and which implies a readiness to act upon our knowledge, must come from some other part of our nature, which can be no other than the sources of action. See Belief.

So much as regards the human instincts. The mental activity of the lower animals is much less perfectly understood, and no sufficient observations exist to enable us to draw clearly the line between the intuitive and the acquired powers in any single species. The popular tendency has been to under-rate the acquired knowledge of animals, if not to ignore it altogether. It is then made a matter of vulgar marvel that they should do by inborn power what human beings require an education to perform. We even attribute to them something like a human inspiration, as when we speak of the bee as a geometer, of the swallow as a meteorologist, and of the beaver as an architect, implying that these creatures have found a royal road to the sciences. The facts confidently asserted and universally believed respecting animals so familiar as the chick and the duckling are, really, if examined, such as to stagger credibility, for they involve in these creatures the knowledge at birth of the facts of the external world, as when it is affirmed that the duckling knows on first seeing water that this is its proper element, where it can swim and float, instead of walking awkwardly on its two feet. Now, although such knowledge a priori of the matter of fact is not intrinsically impossible, yet it is so completely at variance with all our best grounded observations, that we must pronounce it incredible, until it shall be established by at least some hundreds of unequivocal experiments made for its congruity, as is likewise said that the chick recognises grains of corn at first sight, and can so direct its movements as to pick them up at once; being thus able to know the meaning of corn and distinguish it from other things intuitively, and to graduate its movements to that knowledge—all which is, in the present state of our acquaintance with the laws of mind, wholly incredible. It may be possible, not only for the incredibility to be removed, but also for the animals themselves to be established as true; but the evidence requisite for that purpose has never yet been obtained.

The same uncertainty attaches to those far-sighted provisions that are made by certain animals for their own future wants and for their progeny yet unborn. The precise immediate motives that induce the bird to build its nest, and the circumstances that determine it in the choice of locality, material, &c., have been supposed or inferred from the evidence of our observation, and, indeed, made the subject of exact experimental inquiry. It is not known how far imitation can work in the lower animals, nor to what extent they can derive instruction from the conduct of others. It is a subject of great curiosity to inquire, whether the knowledge of one another's movements, is shewn in many ways: their keeping company and acting in concert imply as much. The analogies of the human feelings, will, and intellect, might go far to explain their conduct, without supposing a mysterious occult revelation made to them specially, and not partaken of by the higher forms of the animal organisation. At present, we are not in a condition to dogmatise, owing to the want of proper observations in the higher animals, and the germ of our scientific ideas as to the human mind has been formed from the striking examples of the mistaken interpretation of the conduct of animals might be quoted in confirmation of the remark now made. See Crochu's Illustrations of Instinct.

INSTITUTE, a term used in Scotch entail law to denote the person who is first mentioned or described as entitled to take the entailed estate. All those who come after him are called substituters. When the institute dies before the entailer, the next person mentioned takes as institute. The laws are certain rules of construction which favour the institute, but these are entirely technical.

INSTITUTE, This, in English Law, is the mode of citation or reference to Chief-justice Coke's great work, in four volumes, on English law. Another name for the first part of it is Coke upon Littleton, owing to its being a commentary by Coke upon a work of Littleton. The second book is a comment on acts of parliament, the third is a treatise on the pleas of the crown, and the fourth on the different kinds of courts.

INSTITUTE OF FRANCE. On the revival of letters, associations for mutual intercourse and co-operation, called Academies (q. v.), were formed in Italy and France, one of which, composed of poets of no great note, was converted by Richelieu into a national institution, under the name of the French Academy, and met for the first time 10th July 1637. The chief object of this institution was the cultivation of the French language; but this was indifferently accomplished, owing to the intermeddling of the court, which arrogated to itself the right of directing the public taste. Many of the judgments of this Academy were strangely erroneous—e.g., its rejection of the Cid of Corneille, and its refusal to admit Molière, Beaumarchais, and La Fontaine. The academy, however, made good use of the preparations of a Dictionary of the French language; but the merits of this work have been
among the ‘associés étrangers,’ there are, in the 3d Academy, Professors Faraday and Owen, Sir D. Brewster, and Sir J. W. Herschel; and in the 5th Academy, Lord Brougham and Mr M’Culloch. Among the correspondents, we find, in the 3d Academy, Sir H. Rawlinson, Mr Layard, and Mr Max Müller; in the 3d, Sir W. Rowan Hamilton, Mr Fairbairn, Professor Airy, Mr Hind, Mr Adamas, Principal Forbes, Sir J. C. Ross, Sir B. Brodie, Mr Forbes, Mr Wedgwood, Mr Adams, Sir W. J. Hooker, Admiral Smyth, and Professor Sedgwick, in the 5th, Dris Whewell and Whately, and Mr Grote. The Académie Française occupies itself with debates on grammar, rhetoric, poetry, and French literature for the preservation of the language and its great work is the preparation of the dictionary and continual improvement of a comprehensive sense, including chronology, geography, numismatology, and the study of monuments of every kind, and of the languages of all nations at all times. It has in its gift a prize of 2000 francs, and another for numismatology. The Académie des Sciences has for its subject statistics, pure and mixed mathematics, medical science, &c.; and has the gift of eleven prizes, several of which are 10,000 francs; all are annual, with the exception of one, which is decennial. The Académie des Beaux-Arts occupies itself with painting, sculpture, architecture, engraving, and music, and with the preparation of a dictionary of the fine-arts, and, alternately with the first Academy, distributes the sum of 1500 francs among poor meritorious authors. The Académie des Sciences Morales et Politiques discusses mental philosophy, law and jurisprudence, political economy and statistics, general and philosophical history, and politics, administration, and finance; and has the gift of two prizes—one decennial, the other quinquennial. There is also a Bordin prize in the gift of each Academy; and two general prizes—one annual, the other triennial—in the gift of the Institute.

Each year a sum is voted by the French government for the general fund of the Institute, and from this fund are paid the allowances of members, salaries of the secretaries and other officials, and several prizes; also experiments, printing, &c.

INSTRUMENT—INSURANCE.

after the 'election' of a bishop by the chapter, or his appointment by the crown, when that right belongs to the crown—it is only the pope who confers 'institution.' In English usage, 'institution' is a conveyance of the cure of souls by the bishop, who, or whose deputy, reads the words of the institution, while the clerk kneels. The institution vests the benefit in the clerk, for the purpose of spiritual duty, who thereupon becomes entitled to the profits thereof. But the title is not complete till Induction (q. v.).

INSTRUMENT, in point of law, is scarcely a technical term, though it is frequently used in England as descriptive of a will or testamentary writing, and often any document not under seal. In Scotland, on the other hand, it is usually descriptive only of a notarial instrument.

INSTRUMENTATION is the arranging of music for a combined number of instruments. The nature and character of the musical ideas must alone determine whether the instrumentation shall be simple or artistic, and perhaps complex; the latter being those cases when some of the instruments take a more prominent part than others. For both purposes, a thorough knowledge of every instrument in the orchestra is absolutely necessary, as without this, instrumentation becomes only a deafening mass of different strings of instruments, from their nature, in most cases, form the principal parts of a score, around which the other instruments move, without depriving them of their importance. The wind instruments represent, more or less, as it were, a subordinate chorus, which may again be divided into two kinds, viz., the wood instruments and the brass, which, with the stringed instruments, give three essentially different choral effects, that may be combined and together in endless variety. A knowledge of the art of instrumentation is only to be acquired by great experience; at the same time, much may be learned by consulting the following works: Die Instrumentenführung für das Orchester, von A. Sundelin, published in Berlin by Wagenführer; and Dr Joseph Fröhlich's Systematischer Unterricht in den vorzüglichsten Orchesterinstrumenten.

INSTRUMENTS, Musical, may be divided into three classes—stringed, wind, and percussion. Stringed instruments are of three kinds: those whose sounds are produced by friction, as the violin, viola, &c.; by plucking, with the finger or otherwise, as the harp, guitar, mandoline, &c.; by striking, as the pianoforte and dulcimer. Wind instruments are of two kinds, viz., the reed species—as the clarinet, bassoon, &c.; and the flute species, as the flute, flageolet, &c. The trumpet, horn, trombone, and all similar wind instruments, are generally classed among the reed instruments; but whether the sound is produced by the lips of the blower acting as a reed, or by the compressed stream of air, as in flute instruments, is not yet determined. Percussion instruments are those which on being struck produce only one fixed sound, as the drum, triangle, cymbals, tambourine, &c. Whatever material may be used to form a musical instrument, there are only two means of producing musical sounds, and these are by the vibrations of a fixed elastic body, such as the string of the violin or pianoforte, the reed of the hautboy, bassoon, &c.; or by the vibrations of a confined column of air put into motion by a stream of compressed air, as in the flute, flageolet, and all the ordinary flute species of organs—pipes.

INSUCKEN MULATURES, in Scotch Law, mean the payments made to the miller by persons who are bound to grind their corn at a particular mill, under a servitude called Thrillage (q. v.). Out-of

sucken mulltures mean the payment for the mere grinding, which strangers pay; and the inscription mulltures include that plus a small premium, which goes to the proprietor of the mill.

INSURANCE, a contract of indemnity, whereby one party, in consideration of a specified payment, called a 'premium,' undertakes to guarantee another against any loss or damage. The first principles of insurance would appear to have been acted on at a very early period, since, without attaching undue importance to the opinions of writers who contend, on the authority of Livy, that they were known during the second Punic war, or that the Emperor Claudius can be considered an insurer, because, in order to encourage the importation of corn, he took all the loss or damage it might sustain upon himself—there are yet extant rules of sound 'guilts,' or several corporations of the Anglo-Saxons, whereby, in return for certain fixed contributions, the members guarantee each other against loss from 'fire, water, robbery, or other calamity.' It was, however, to cover manifest losses that insurance, viewed in its commercial aspect, seems to have been first undertaken. So early as 1435, the magistrates of Barcelona issued an ordinance relating to this class of business, and we find in the speech of the Lord Keeper, in opening Queen Elizabeth's first parliament, the allusion, 'doth not the wise merchant, in every adventure of danger, give part to have the rest assured.' The merit of being the first to apply mathematical calculations to the valuation of human life belongs to the famous John de Witt, pensionary counsellor of Holland, whose Report to the States-General, on the valuation of life annuities, has been lately brought to light by Mr. M. Hamburger. The first insurance company established in Britain appears to have been the 'Amicable,' founded in 1696; not the office known by that name now, but the one that still exists as the 'Hand in Hand.' Omitting the gambling and other objections to projects for which the science of insurance has been held responsible, it would exceed the limits of the present article to give any detailed account of even the more legitimate applications of it which are current at the present day; the traveller can be protected from the pecuniary losses entailed from damage by rail or flood; the gardener from the devastation of the hailstorm; the farmer from the inundations of disease among his cattle; and employer and employer alike reap the benefit of this guarantee. Twenty hundred established offices within the United Kingdom appeared in an accredited list published in 1862, and although there were, besides, 500 working up in Chancery, there is an amount of confidence to be placed in the stability and integrity of the greater number existing, that cannot be exceeded in any other commercial interest. We propose continuing our remaining remarks to the divisions of fire, life, and marine insurance.

1. Fire Insurance.—Although the business of fire insurance is not founded upon such exact data as can be made available in the practice of life insurance, yet considerable progress has been made by the offices towards a correct classification of the risks they run, and the rates of premium range by slight gradations from a minimum of 1s. 6d. per cent., which covers an ordinary private dwelling-house, to 2s. 3s. per cent. and upwards, charged for insuring cotton-mills, sugar-refineries, theatres, and like specially hazardous risks. The average rate of premium received for risks in the United Kingdom may be estimated at 4s. per cent. A duty of 3s. per cent. on an annum is levied by government upon all fire insurance, except farm-mills and public hospitals, and the parliamentary returns are of it.
afford valuable statistical information of the total amount insured. The duty paid in the year 1860, per return last published, amounted to £1,538,608, representing a gross amount insured over the year of £1,039,072,140, and there was likewise covered by the different companies, farming-stock to the extent of £73,309,888. The effect of such a heavy impost as the duty, is felt to be a serious impediment to the progress of fire insurance, although the case and an assurance of £1 payable at the end of the great inducements to successive chancellors of the exchequer to perpetuate the tax. Conceding that the revenue must be obtained, a tax on prudence certainly seems an objectionable method of raising it, and it is likewise found to be an inequitable one.

A very large proportion of the whole property insured is covered at the minimum rate of 1s. 6d. per cent, and from this the office having to pay its agency and other expenses of management, it is hardly too much to say that in such cases the tax is threefold the net premium required to cover the risk. Fire insurance policies are of too familiar use to require explanation here, but one point in connection with them may be noticed. By certain policies, they guarantee the insured to the extent of the whole amount specified in them, without regard to the excess of value of the entire property before the fire; unless an exceptional 'average clause' is attached to the policy. 2. Life Assurance, in its widest sense, is a contract entered into by the assurer to pay a certain benefit contingent upon the duration of one or more lives. The 'present value' or single premium corresponding to an assurance of £1 payable at the end of the year of death of an individual, is deduced from the value of an annuity on the same life (see Annuity), and is expressed by the formula \( s - (1 - r) A_x \), where \( s \) is the sum which will amount to £1 in one year (therefore equal to \( 1 + r \), \( r \) being the interest of £1 for a year), and \( A_x \) is the value of an annuity of £1 per annum on the life aged \( x \).

The more common form in which a life assurance is carried out is, however, by the payment of an annual premium to the company assuring, and this is determined (using the same symbols as above) by the formula \( 1 + A_x \) (\( 1 - r \)). The demonstration of which, in a popular form, is thus ingeniously done by Mr Gray. The present value of an immediate annuity, a life aged \( x \) years, of which the first payment falls to be made at the commencement of the transaction—being \( 1 + A_x \)—is easily deduced by proportion that £1 will purchase an immediate annuity of \( 1 + A_x \), the reciprocal of the first value; and this would be the proper premium for the benefit if the latter were paid to the assured at the beginning of the first, and not at the end of the last year of the duration of the policy; but insomuch as the benefit is not received until the close of the stipulated period, the difference between its immediate value and its value if due a year hence (\( 1 - r \) v) has to be deducted from each year's premium, and the formula is the result.

An allowance of mortality in the calculation of office-premiums are—the rate of interest which is to accrue from their investment, the mortality returns with which the future experience of the insured is expected to agree, and the proportion or 'loading' to be added to the net rates to meet expenses of management, and afford a profit to the insurer. The rate of 3 per cent. has, with a very few exceptions, been adopted as a basis for such calculations, as the nearest to what can be expected to be realised on good security for transactions extending over many years. The mortality table most generally in use is that originally published by Mr Milne, derived from the observations of Mr Hanyon of the rate of mortality in Carlisle during the nine years 1779 to 1877 inclusive, and hence known as the Carlisle Table. It is admitted to be a correct representative of healthy life in England, and from the great number of published compilations founded on it, is likely to retain its place in the estimation of actuaries.

The following are examples of net premiums calculated on these data:

<table>

</table>

The question of the addition to be made to such (net) premiums is influenced by different considerations having regard to the practice of the office using the table.

Assurance companies are divided into three classes: 1. Proprietary Companies, being those offices possessing a capital the property of the partners, and which, in addition to the accumulated premiums, is pledged to the policy-holders as a guarantee for the fulfilment of their claims. As the liability in such companies is limited to the net sums assured, the addition made to the premiums requires to be only such a proportion as will cover the actual outlay for management, and remunerate the shareholders for the risk of loss by fluctuation in the mortality, or from bad investments, which they run. A comparison of the above premiums with the 'non-participation' rates usually advertised, will show that the prevailing competition has induced the construction of tables very favourable to the public. 2. Mutual Offices, where the members themselves constitute the company, being liable to each other for all claims. Here, in the absence of a capital, it is usual to adopt a scale of premiums known to be in excess of what is required to meet the sums insured. The profit arising therefrom is periodically ascertained, and allotted to the assured, most frequently in the form of 'bonuses' or additions to the claims payable under the policies. Some companies doing a large business are of this class, and in point of stability and irreproachable management bear the highest character. 3. Mixed Companies are proprietary companies charging such increased rates as will yield a bonus, but which, in return for the expenses of management and guarantee of their capital, reserve for their proprietors a stipulated proportion of the profits. It would be beyond our province to deal with the comparative merits of these systems; undoubtedly, offices in which the assured participate in a part or the whole of the profits, have for some years back enjoyed the largest share of public support. Life assurance, in the abstract, is certainly one of the greatest blessings of modern times. The extent to which it has been made available may be judged from the fact, that the total sum, including vested bonuses, for which the existing offices are liable is estimated at about £200,000,000 sterling; the
annual premiums payable, therefore, being between five and six millions—a sum equal to 24th of the net public revenue of the United Kingdom.

A greatly increased facility for making the necessary calculations in connection with life-assurance has been developed within the last few years by the use of 'Commutation Tables,' the invention of Mr. George Barrett, and of which a large collection, calculated by Mr. D. Jones, is published by the Society of the Diffusion of Useful Knowledge. To secure the best information on their construction, and other formulae, the reader is referred to the standard works of De Morgan, Gray, Milne, and the transactions of the Institute of Actuaries, published quarterly.

3. Marine Insurance.—Although this branch of the subject does not possess such a general interest as the preceding, it is one that requires quite as great an amount of study and experience to insure its successful prosecution. In estimating the rate of premium, the insurer has to take into account not only the quality of the vessel covered, but the season in which she sails, the known character of her commanders, the nature of the cargo and the port of destination, and (the contract being an indemnification both against the elements and the enemy) the state of our political relations. Nevertheless, losses at sea, like other incidents, are observed to follow certain laws, and the average from which the value of the rate is deduced is of sufficiently broad basis, the result over equal intervals of time can be predicted with reasonable certainty. Until 1824, the only companies that could grant marine insurances were the 'London Assurance' and 'London and Highland Insurance;' and although the monopoly of these offices then ceased, and various other companies were established, such is the force of usage, that by far the greater portion of the business continues to be transacted by individual insurers designated 'underwriters.' The underwriters of London form an influential society known as the 'Lloyd's' (q. v.) from having originally met in a coffee-house kept by a person of that name in Aheurh Lane; and their extensive business, numerous agents for procuring information, and general influence in the mercantile community, have long gained for them a world-wide reputation.

As a small number of risks, viewed in connection with the great hazard to which property at sea is exposed, would not secure a safe average to the individual insurer, he finds it prudent to take but a fractional part of the entire risk on himself, and this is done by subscribing or 'underwriting' the stipulated proportion on a policy drawn out for the whole amount to be covered. The necessity for circulating the policy for this purpose, and otherwise negotiating the insurance, has given rise to another business, that of the 'insurance broker,' which, however, that of the underwriter is often combined. A system of mutual insurance is frequently carried out by associations of ship-owners forming 'clubs,' differing in some degree from the protection afforded by the ordinary underwriter, insomuch as a club grants an indemnification for the loss for which the insured may at law be held responsible for damage done by his ship to another. As such a 'collusion' guarantee is now frequently held as a stipulation in an ordinary policy, this distinction is, however, gradually disappearing.

Marine insurance differs from an ordinary fire insurance, in respect that in case of partial loss the underwriter pays only such a proportion of the sum insured as the damage sustained bears to its whole value at the time of insurance. See AVERAGE. In adjusting a partial loss, it is usual to deduct one-third of the nominal value, for new materials furnished to replace the older destroyed, and labour. Policies are of two kinds, 'valued'—where the insurance is based on a specified bill of lading—and 'open,' where, in case of loss, the value of a ship with her stores is estimated as at the date of sailing, her freight at the amount she would have earned on the voyage terminated favourably, and her cargo at its invoice price, adding premium and all charges. The insurance is binding although the ship may have been lost when the policy was executed, but any warranty, if not true, will vitiate the insurance, even although the misstatement is not material to the risk. A stamp-duty is levied upon all marine insurance policies, although well-grounded objections are urged against it. A tax on prudence, it is unfairly made to increase whilst on the amount of the coasting traffic, it passes unequally on the caravans by sea in competition with the land traffic on which no such burden is imposed, and in other business is offered no such temptation to the foreign in preference to the British underwriter. In fixing the amount of stamp-duty, the choice lies with the insured of doing so with reference to the term of insurance (not exceeding one year), or to the rate of premium per single voyage, by the following table:

<table>
<thead>
<tr>
<th>Rate of Premium</th>
<th>Not exceeding 10% per cent.</th>
<th>0 to 2 per 100</th>
</tr>
</thead>
<tbody>
<tr>
<td>Exceeding 50%</td>
<td>5</td>
<td>2</td>
</tr>
<tr>
<td>Exceeding 100%</td>
<td>10</td>
<td>4</td>
</tr>
</tbody>
</table>

The revenue of the government from this source was for the year ending March 1861, £2,238,733, but although this was a slight increase on the amount of previous years, it has been shewn, from returns obtained by Mr. Leoni Levi, that the proportion of vessels insured to the number of wrecks has over the same period been gradually diminishing, a diminution in the ratio of insurances which Mr. Levi attributes to the pressure of the duty.

INSURANCE, IN LAW.—The law on the subject of insurance is substantially the same throughout the United Kingdom.

Fire Insurance.—The contract is generally preceded by proposals, in which case the proposals and policy of insurance must be read together, if the policy refers to these proposals. In order to insure property, the insured must have some interest in the property insured, for otherwise there would be an inducement to commit arson. But he need not be owner; it is enough that he be accountable for the goods, or hold a lien on them, as a carrier, wharferinger, or bailee. Thus, many carriers keep up a floating policy to cover all goods which may happen to be on their premises within a given period. In all these cases, the words of the policy are of important points; and good faith is required in giving a correct description of the goods or premises, for every statement or representation as to anything that is essential is taken to be a warranty. The premises must not be materially altered during the risk; otherwise the policy will be void; but often the policy stipulates that alterations may be made on giving notice. A person in lodgings may insure his goods, and may safely call the house his 'dwelling-house' for that purpose. But, as a general rule, grants are not required to be described in the insured not to misrepresent any material matter, and not to conceal any extraordinary risk which the insured ought to know. If a fire happens, enter on the premises, or in neighbouring premises, the
INSURANCE—INTAGLIO.

insurer cannot set up in defence that it was caused by the negligence of the insured or his servant, for these are generally the very things which an insurer has instanced as the ground of a void of contract, if a fire happen, it is generally always provided by the policy that notice of the loss is to be sent in, and full particulars of the damage done, and the alleged value, for it is only the actual loss which is insured against. If the fire person insures his house or furniture for £500, and damage only to the extent of £200 has been done by fire, he can only recover the £200, for otherwise he would be better off than he was before the fire, and the Indian, if one merely let his house, it, and not add to one's wealth, but merely secures against loss. It is often provided that the annual payment of the premium on a contract of insurance may be paid within 15 days after the first or previous year has expired, but it is dangerous to allow the payment to be postoned so long, for if a fire happen in the interval, the insurer will not in general be liable. Sometimes the same property is insured in several policies, and in case the insured party can nevertheless only recover the extent of the sum once and no more. He can sue either of the insurers, however, for the amount, if each policy cover the whole value, and the party who pays can then recover the extent of his liability from the other insurers, for they all divide the loss among them. In cases where carriers and others take out a floating policy of fire insurance, the carrier can sue for the full loss of the goods, though for exceeding the extent of his own interest in them, but in this case the owner of the goods destroyed is entitled to recover the balance from the carrier, even though originally he never gave authority to the carrier to insure them. And so, in like manner, if a person is interested in one partly lost, it, and it then suing a third party for the wrong which caused the loss, the insurer gets the benefit of what may thus be recovered, in diminution of his own loss.

Life Insurance is not a contract of indemnity, like fire insurance, and therefore a person may insure his life in as many insurance offices as he pleases, and his executors will recover the full amount insured from each of the insurers, regardless of the rest. In order, however, to insure a life, the insurer must either himself be the life or must have a present interest in the life. Thus, a creditor is entitled to insure his debtor's life; a wife may insure her husband's, because he is bound to support her; or the agent in the case of an annuity or property settled upon her for life, in which he has an interest. It is enough, also, that the interest of the insurer exist at the time the policy is entered into, and hence, though the interest afterwards cease, he will still be entitled to recover the amount, if the policy is kept up. Thus, a creditor whose debt is satisfied, may still recover on the policy. In entering into contracts of life insurance, scrupulous good faith is exacted in the description of the nature of the life insured, and any fraudulent misrepresentation in a material point is fatal to the insurer's right to recover. Some companies even go the length of inserting in their policies a clause, that if any misrepresentation (i.e., every trilling) be made, the policy will be void. But these contracts should be taken to avoid such offices, for the policies taken out on such terms will generally be so much waste paper, as far as any security is concerned. At the same time, it is often dangerous for the insurer to treat lightly any misrepresentation, for in the end the question, whether it is material or not, will be one not for him or his executors, but for a jury, in case an action is brought. When the policy is effected through an agent on the principal's life, and the agent, unconsciously and without the authority of the principal, makes a misrepresentation, this will bind the principal. Where the person whose life is insured consents, either, or is hanged, the policy is void, unless, in the case of suicide, it was in a state of insanity at the time. The policy, however, frequently has an express provision on this subject, the terms of which will be in that case all-important, and will govern the extent to which the policy provides, as it often does, for its continuance, if payment after the expiration of the year is made within 15 or 21 days, it is dangerous to run the risk of this interval, for if the party dies during the 15 days before the premium is paid, the policy will not be set up by his executors coming forward to pay within those days. But the policy sometimes expressly allows of this, in which case it will be competent for the executors to make the payment. Life assurances are often assigned in security of a debt, in which case the assignee generally covenants to pay the premiums, so as to keep the security up; and failing payment by the assignor, the assignee is generally authorised to pay them and recover them from himself, and the assignor lose from the annuity. Notice of an assignment of a life policy should always be given to the insurance company, so as to let them know whom they are to pay.

Maritime Insurance is effected from one port to another, in which case it is called a voyage policy, or it is from one given day to another, in which case it is called a time policy. When the value of the property insured is expressed in the policy, it is called a valued policy, and when not so expressed it is an open policy. In general, wagering or gaming policies are void by statute, and the insurer must have some interest in the ship, such as the profits of the voyage or the security of some sort of sea-wages, however, is not competent, for it tends to take away the stimulus of exertion from the crew. When the policy states a fixed sum as the value of the property, and expressly provides that the policy shall be deemed sufficient proof of insurance, this insurance is an insurance interest or no interest, and void by the statute. When the policy is a voyage policy, there is an implied warranty by the insurer that the ship is sound at the commencement of the voyage, but there is no such warranty in a time policy. As is the case in fire and life policies, any fraudulent concealment of material circumstances which increase the risk will void the policy. But if with the knowledge of the insurer an act of navigation and trade is presumed to have been foreseen, and in contemplation of both parties. The policy is understood to cover the risk, not only of the perils of the sea, properly so called, but of ignorance or negligence on the part of the master or mariners. But the loss caused by mere tear and wear is not covered by the policy; the cause of the loss must be something fortuitous or accidental. Every policy implicitly assumes that the vessel will proceed straightway to her place of destination, without unnecessary delay. But sometimes, from unforeseen causes, it is absolutely necessary for the master to deviate, in which case, and in which only, the policy will remain good, strict proof, however, being always requisite of the imprudence. When the ship has been so injured or deteriorated as to render it hopeless to restore it, and the repair will cost more than the ship is worth, the insurers may abandon the ship, and claim for a total loss. See AVERAGE.

INTAGLIO (Ital. 'cutting in'), a term in art, the opposite of relief (see ALTO-BILIEVO), means the representation of a subject by hollowing it out in a gem, or other substance; so that an impression
taken from the engraving presents the appearance of a bas-relief.

INTEGRAL CALCULUS. See CALCULUS.

INTEGRATION. See CALCULUS.

INTELLECT, the name for the thinking portion of our mental constitution. Mind contains three

elementary constituents—Emotion or Feeling, Volition or the Will, and Intelligence or Thought. See also Emotion. The mental powers are

explained in part by their contrast with feeling and will. When we enjoy pleasure or suffer pain, we are said to feel; when we act to procure the one or avoid the other, we put forth voluntary energy; when we remember, compare, reason, our intelligence is

exerted.

The powers of the intellect have been variously classified. Among the commonly recognised designations for them, we may mention Memory, Reason, and Imagination, which imply three very distinct applications of our mental forces. Reid classified them as follows: Perception by the Senses, Memory, Conception, Abstraction, Judgment, Reasoning. Stewart added Consciousness, to denote the power of judging of our mental states, as Sensation and Perception make us cognizant of the outer world; likewise Attention (a purely voluntary function, although exerted in the domain of intelligence), Imagination, and the Association of Ideas.

It might be easily shown that in such a classification as the above there is no fundamental distinctness of function, although there may be some differences in the direction given to the powers. There is a faculty of Memory which follows all memory, and nothing but memory. Reason and Imagination equally involve processes of recollection. And with regard to the Association of Ideas, it has been shown by Mr. Samuel Bailey (Letters on the Human Mind) that if this is to be introduced into the explanation of the intellect, it must supersede the other faculties entirely; in short, we must proceed either by faculties (as Memory, Reason, &c.) or by Association, but not by both.

In endeavouring to arrive at a satisfactory account of the human intellect, we must make a deeper analysis than is implied in the foregoing designations. We find at least three facts, or properties, which appear in the present state of our knowledge to be fundamental and distinct, no one in any degree implying the rest, while taken together they are considered sufficient to explain all the operations of Intelligence, strictly so called.

1. Discrimination, or the consciousness of Difference. When we are affected by the difference of two tastes or colours, or sounds or colours—this is neither mere feeling nor volition, but an intelligent act, the foundation of all other exercises of our intelligence. We must recognise the impressions on our senses as differing, before we can be said to have the impression of anything; and the greater our powers of discrimination in any department, as colour, for example, the more intellectual are we in that respect. P. 280.

We could be no memory if we did not first recognise distinctness of character in the objects that act on the senses, and in the feelings that we experience. In some of the senses, discrimination is more acute than in others; thus, Sight and Hearing give us a greater variety of impressions than Taste or Smell, and are therefore to that extent more intellectual in their nature. In the course of our education, we learn to discriminate many things that we confounded at first. Every craft involves acquired powers of discrimination as well as habits of manipulation. A man is in one respect clever or stupid, according as his perceptions of difference in a given walk are delicate or blunt.

2. The next great intellectual property is Retentiveness, or the property whereby impressions once made persist after the fact, and can be afterwards recovered without the original cause, and by mental forces alone. When the ear is struck by a sound wave, we have a sensation of sound, and the mental excitement does not die away because the sound ceases; there is a certain continuing effect, generally, although not always, much feebler than the actual sensation at the time. The sensation has completely vanished, and been overlaid by many other states of mind, it is possible to evoke the idea of it by inward or mental links, shewing that some abiding trace had been left in the mental perception; in this other, Self-consciousness, and so be found in the so-called forces of Association. See Association of Ideas.

3. The last great fundamental fact of intellect is Agreement or Similarity. See Agreement of Ideas.

It is believed that these three properties, in combination with the other two powers of the mind (Feeling and Volition or Will), are adequate to explain all the recognised intellectual faculties or processes. Memory, Reason, Imagination, &c., Memory is almost a pure case of Retentiveness, or Contiguity, aided occasionally by Similarity. Perception by the senses is only another name for Discrimination. The association of ideas follows the appreciation of matter or mind. Judgment is either Discrimination or Similarity, according as it discovers difference or agreement in the things judged of.

Sir W. Hamilton, in departing from the common classifications of the intellect, exhibits the following division into six faculties or powers. 1. The Presentative Faculty, by which he meant the power of recognising the various aspects of the world without and the mind within, called in the one case External Perception; in the other, Self-consciousness, and sometimes Reflection. 2. The Conservatory Faculty, or Memory proper, meaning the power of storing up impressions, to be afterwards reproduced as occasion requires. 3. The Reproductive Faculty, or the means of calling the dormant impressions up into consciousness again. These means are, as stated above, the Associating principles. 4. The Representative Faculty, for which imagination is another name, which determines the greater or less vividness of the impressions or ideas thus reproduced. 5. The Elaborative Faculty, or the power of Comparison, by which Classification Generalisation, Abstraction, and Reasoning are performed. This, in fact, is one (not the only) application of the general power of Similarity. Lastly, 6. The Regulative Faculty, or the cognition of the a priori or supposed instinctive notions of the intellect, as Space, Time, Causation, Necessary Truths, &c. This corresponds to what in German philosophy is called the 'Reason,' as contrasted with 'Understanding,' which deals with experienced or contingent truth.

On examining the above distribution, it will appear that while the first faculty, the Presentative, coincides with the primary fact of Discrimination, the three subsequent, Conservatory, Reproductive, Representation, are merely modes or distinct aspects of Retentiveness. All the three must concur in every case of the effective retention or recollection of anything at all about the intellect, although it is more or less disputed by the opposite school, who refuse to recognise a primary or distinct faculty as giving birth to the ideas in question. See Consciousness, Cause.

INTEMPERANCE. See INTOXICATION.

INTENDANT, or INTENDANT MILITAI"
INTERCALARY—INTERDICT.

under his orders are those in charge of all the finance services, the provisions, stores, hospitals, artillery, train, and transport departments, besides the interpreters, guides, and such like temporary services. The intendant-in-chief of an army is the representative of the Ministry of War, and subject to the orders of the general's orders, can exercise, in case of need, all the functions of that high officer of state. The intendance is divided into intendants, ranking with general officers, sub-intendants with colonels, and assistant-intendants with majors; besides cadets who receive no pay, and constitute a probationary grade.

During the Crimean campaign, the necessity of such a department in the British service was keenly felt, and it was established.

The interdict, the penalty, is the withdrawal of the sacraments, of the celebration of public worship, and of the solemn burial-service. Interdicts are of three kinds—those in which the condemnation is public, and thus comprehended all, without distinction, who reside therein; personal, which only affect a person or persons, and which reach this person or persons, and these alone, no matter where found; and mixed, which affect both public and private. In all cases, the effect is that the latter would be bound by the interdict even outside of its purely local limits. The principle on which this ecclesiastical penalty is founded may be traced in the early discipline of public penance, from which pendents were for a time debarred from the sacraments, and from the privilege of presence at the celebration of the Eucharist; but it was only in the medieval period that, owing to circumstances elsewhere explained (see EXCOMMUNICATION), it came into use as an ordinary church censure in the then frequent conflicts of the ecclesiastical and civil power. It was designed to awaken the national conscience to the nature of the crime, by including all alike in the penalty with which it was visited.

The most remarkable instance is the interdict enforced in Scotland in 1180 by Alexander III.; on Poland by Gregory VII., on occasion of the murder of Stanislaus at the altar; by Innocent III. on France, under Philippe Auguste, in 1200; and on England by John in 1299. The description of England under the last-named interdict, as detailed by some of the contemporary chroniclers, presents a strangely striking picture of the condition of the public mind, which it is difficult for our modern ideas fully to realize or to understand. It would be a great mistake, however, to suppose that, during the continuance of an interdict, the people were entirely destitute of spiritual assistance. The interdict mainly regarded the "soul-side" of public worship; it was permitted to administer baptism, confirmation, and the Eucharist in all cases of urgency; to confess and absolve all who were not personally guilty participants in the crime which called for the interdict; and in all cases of marriage, but without the solemnities; and to confer orders in cases of necessity. And under the popes Gregory IX., Innocent III. and IV., and Boniface III., still further mitigations of its length were introduced, one of which was the removal of the interdict and restoration of public worship on certain great festivals, especially Christmas, Easter, Pentecost, Assumption, and All Souls. The council of Basel enacted very stringent rules as to the use of this penalty, and in later times the general interdict has been entirely disused, although occasionally, in very special circumstances, and to mark the horror of the church for some enormous crime, instances are still recorded in which a particular place or church has been visited with the penalty of a local interdict.

INTERDICT, in Scotch Law, is an order issued by the Court of Session to stop or prohibit a person from doing an illegal or wrongful act. It is obtained by presenting a note of suspension and interdict to the Lord Ordinary on the Bills. The party applying for it must have both title and interest—that is, he must be more than a mere stranger. The principles on which it is granted in Scotland are substantially the same as those on which, the parallel Order of Injunction (q. v.) is granted by the Court of Chancery in England.

INTERCOMMUNING, LETTERS OF, was an ancient writ issued by the Scotch Privy Council, warning persons not to harbour rebels.
INTERESE TERMINI—INTEREST.

weakness—then called voluntary interdiction—or may be restrained by the Court of Session in voidum, then called judicial interdiction. The effect of both is to appoint trustees or interdictors, whose consent is necessary to all deeds whereby the impecunious heritable estate is alienated. See IMPEDIBILITY.

INTERESE TERMINI, a term sometimes used in English law to denote the kind of interest which a lessee takes in land when the lease is extinguished. It amounts to a right of entry on the lands, which is assignable.

INTEREST, the payment due by the borrower of a sum of money to the lender for its use. The interest of £100 for one year is called the rate per cent.; the money lent, the principal; and the sum of the principal and its interest, the amount. The current or market rate of interest fluctuates widely, by reason, not, as is often supposed, of the extent of the supply of money, but of the variable rates of profit, as in Holland, where it has always been comparatively low, and in our own time in Australia and California, where mercantile profits being in excess, the rate of interest is relatively high.

A strong prejudice against exacting interest existed in early times, arising from a mistaken view of some enactments of the Mosaic law;* and as late as the reign of Edward VI., there was a prohibitory act passed for the alleged reason that 'the charging of interest is against God, most odious and detestable, and contrary to the word of God.' Calvin, the famous reformer, was one of the first to expose the error and impolicy of this view, although a series of enactments, known as the Usury Laws, to some extent controlled it, by an attempted restriction of the maximum rate to be paid. In England, this rate was fixed by act 21 James I. at 8 per cent. During the Commonwealth, it was reduced to 6 per cent.; and by the act 12 Anne, c. 16, to 5 per cent., at which rate it stood till 1839, when the law was repealed. In Scotland, any charge for interest was prohibited before the Reformation. In 1587, the rate was fixed by law at 10 per cent.; in 1653, at 8 per cent.; in 1691, at 6 per cent.; and by the act of 1780, at 5 per cent., at which rate it stood till 1825. It is now admitted that the operation of such laws tended only to raise the real rate of interest, by driving men in distress to adopt extravagant methods of raising money—the bonuses thus paid being really and in effect an addition to the nominal interest.

Interest is computed on either of two principles:

1. Simple interest, where, should the interest not be paid as due, no interest is charged upon the arrears. Although this mode of reckoning has little to recommend it in reason, it is adopted in many transactions, and receives the sanction of the law. The computation of simple interest is easy; it being only necessary to calculate the product of the principal, the rate per cent., and the period in years and fractions of a year, the result, divided by 100, giving the sum required. Thus, wanted the interest of £50, at 5 per cent., for 3 years, £75.

2. Compound interest is the charge made where—the interest not being paid when due—it is added to the principal, forming the amount upon which the subsequent year's interest is computed. The rules for most readily making computations by compound interest can only be effectually expressed algebraically, and, using the symbols in article DISCOUNT, we annex a few of the elementary formulæ.

1. Since £1, increased by its interest r, at the end of one year becomes 1 + r, this amount at the end of the second year becomes (1 + r), and generally at the end of the n-th year (1 + r)n. Example: To find the amount of £1, improved at 5 per cent. for six years, the interest for £1, is 106, and n = 6; therefore (1.05)6 = 1.32, or £1. 5s. 9d. 2. Since £1, in year 1 + r, it is apparent by the elementary proportion that the fraction of £1 which will amount to £1 in a year is (1 + r)−1, and, reasoning as above, the sum which will amount to £1 n years hence is (1 + r)−n. The amount of £1, in n years being (1 + r)n, it will be seen that the excess of this sum over the original £1 invested, or (1 + r)n − 1, is the amount of an annual increment or 'annuity' of £r for the period, and from this, by proportion, is deduced the formulæ for the amount of an annuity of £1 for the same time, being

\[
\frac{1}{r} (1 + r)^n - 1
\]

3. Tables for the class of values above described, based on various rates of interest, are given in most works on annuities. Those by Mr Race are computed for each quarter per cent. from 1 to 10 per cent. It may be useful to state two results that can be easily deduced from a table of the present values of annuities (4). 1. The annuity which £1 will purchase for any number of years is the reciprocal of the corresponding value in such a table. Example: A person borrows £100, to be repaid by annuity in 15 years, with interest at 5 per cent.; required the annuity? The present value of an annuity of £1 per annum for that period, at the rate stated, is £0938, and 100 × 10938 = 9376. 2. To find the annuity which in a given period will amount to £1—subtract from the annuity that £1 will purchase, ascertained above, the interest of £1 for a year. Example: The annuity which, paid for 15 years, will enable to £1, to take interest at 5 per cent. Value of annuity which £1 will purchase as last found, £009342. Subtract r, at 5 per cent., £005000.

Annuity required, £046342. Or £24 12s. 9d. will amount in 13 years to £100.

INTEREST, IN LAW.—In England and Ireland, when a debt has been for some time due, there is no obligation imposed on the debtor by the common law to pay any interest whatever, though the sum has been fixed and often demanded. The creditor can always sue for his debt, which is its proper remedy, but he derives no benefit from giving time to his debtor. Therefore, if interest is to be paid, this must be, as a general rule, by virtue of express agreement. Nevertheless, there has always been some exceptions to this rule. Thus, by the usage of merchants, it has always been usual, when an action has been brought to recover the amount of a bill of exchange or promissory note, for the jury to add interest from the time it was due; but even this was not a matter of course—it was a matter of discretion for the jury, and was generally withheld when there was delay in bringing the action. Another exception existed

* See Exodus, xxii. 25; Leviticus, xxv. 39; Deuteronomy, xxiv. 19: the application being to money lent for the relief of distress, and not advanced to the borrower that he might improve it.
INTERFERENCE—INTERLAKEN.

in the case of money due upon an award by an arbitration in respect of which cay was due from the day when the award was made. A third exception was in the case of a bond for money, in which case interest was added from the day it ought to have been paid. And lastly, if a surety had to pay money for his principal, he could recover it back with interest. In all other cases, if there was no express agreement about interest, none could be claimed. If, however, there was a course of dealing between the parties, or a usage affecting a particular trade to give interest, then, without express agreement, this was understood. A recent statute somewhat amended the above defect of the common law, for by 3 and 4 Will. IV. c. 42, s. 28, a jury may now add interest at the ordinary rate on all debts or sums certain, which are made payable under some written instrument at a certain time; and even if not due under a written instrument, then if a written demand has been made, expressly giving notice to pay in each case. If the debts met after the date of the demand, if not paid then, interest will also be due. But even in these last cases, it is discretionary in the jury to give the interest, and therefore it is not claimable as a matter of course. In the most decided cases of interference, it is a forlorn not claimable in any case, except where it has been expressly stipulated for, or where there is in some particular trade a definite custom to pay interest, and such custom must always be proved.

It ought also to be added, that the Court of Chancery has always been in the habit of charging trustees who have misapplied funds with 5 per cent. interest on the amount, and also compound interest thereon, in simple cases of money in hand without investing them, they have been charged 4 per cent. Formerly, it was prohibited by statute in England to lend money on the security of real estate at a higher rate than 5 per cent.; but these statutes have been abolished, and now any person may borrow or lend at whatever rate of interest he can agree with the other party. Pawnbrokers are allowed to charge interest not exceeding a fixed sum. See Pawning.

In Scotland, the law has always been much more liberal in allowing interest to be claimed on standing debts, for there the converse principle was acted on, that on nearly all debts whatever, interest was chargeable either by statute or by common law. Thus, interest is due on bills of exchange, on the amount contained in ahorning or charge to pay, on sums paid by cautioners, on the price of lands sold, on money advanced at request, on the price of goods sold, if the usual time of credit has expired, and generally on all debts which there has been delay in paying.

INTERFERENCE, a term employed to express the effect which rays of light, after being bent or diffracted, produce on each other. If the rays met after diffraction, their light, when allowed to fall on a surface, will be divided into bars or stripes, alternately light and dark, as is shown in the article DIFFRACTION (q. v.). This phenomenon has been made the foundation of the theory of the interference of light, the undulatory and the emissive. According to the former, it is thus explained: if two luminous waves simultaneously impinge a molecule of ether, their motion will be the resultant of the two impinging on it. This resultant wave will be nearly in the same direction, the resultant will be nearly their sum; if opposite, their difference. Thus, when a particle has begun to undulate from the action of a luminous wave, if, while in motion, another wave impinge upon it, the result will be increase of light, if the motion of the second wave conspire with that of the first; but a decrease, if they oppose each other; and therefore, while opposing, they are equal in velocity. Let be the distance corresponding to a complete period of vibration; then, if the second wave impinge upon the molecule after it has accomplished one or more whole vibrations corresponding to the distances 2, 3d, 4d, &c., and has returned to its original position, the two waves will evidently conspire together, and produce more violent motion; but if it impinge on the molecule, when the latter has only accomplished half a vibration, corresponding to distances of, 4d, 5d, &c., then the wave will oppose the particle's return to its original position; and thus producing diminution of motion, or, if equal, rest. In the former case, the intensity of light is increased; in the latter, diminished; and if the undulations are of equal velocity, the light is doubled in the first case, and destroyed in the second. The emission theory totally fails to explain interference. In light of different colours, the value of d differs for each colour, being least for violet, and greatest for red light. The principle of interference accounts in the most satisfactory way for the colours of thin plates, the fringes that accompany shadows, &c.; and its explanation forms the basis of a large and important branch of modern science, known as interferometry.

INTERLAKEN, between the lakes, a village of Switzerland, is delightfully situated on the right bank of the Aare, in a plain between Lakes Thun and Brienz. Along the Walnut Avenue or Highway,
INTERLINEATIONS—INTERMARRIAGE.

between the lakes, there is an almost uninterrupted line of hotels or pensions. Within a few miles of the village are many of the most wonderful sights that the country affords. Ten miles southward is the Staubbach (the ‘sky-born waterfall’), with its perpetual iris; a few miles further south, and in

full view from the village, are the magnificent Jungfrau and several other remarkable peaks of the Bernese Alps. The visitors are the chief source of income to the inhabitants, who number from 1000 to 2000.

INTERLINEATIONS in a deed are additions or corrections written either on the margin or between the lines. In England, interlineations in a deed are not fatal, provided only it is proved that they were made before executing the deed. It is usual to put the parties’ initials opposite the place where the interlineations occur, in proof of this, or at least by way of memorandum. In affidavits and other documents, the initials should also be put at the places interlined. In Scotland, if the interlineation is at all material, it ought to be signed by the parties, and the fact mentioned in the testing clause, otherwise it will be presumed that the interlineations were made after the execution, and will vitiate the deed.

INTERLOCUTOR, in Scotch Law, means a finding or judgment of a judge or court in a cause. In England, the word is not used.

INTERLOCUTORY JUDGMENT, in England, Ireland, and Scotland, means a judgment which is not final, but which is merely a step in the suit or action. So as to interlocutory decrees or orders.

INTERLUDE, in Music, is a short melodious phrase played by the organist (generally extemore) between the verses of a psalm-tune. In the German Protestant Church, the interlude (or zwischenpièl) is generally played between each line of the verse, to give the congregation time to breathe. To accompany the chorale of the Lutheran Church with scientific and appropriate interludes, is reckoned in Germany the chief test of a good organist.

INTERMARRIAGE. The intermarriage or intercourse of near relatives has been universally believed to entail degeneracy upon the offspring, and the act has been condemned and prohibited. The physical deformity and mental debasement of the Cagots of the Pyrenees, of the Marrons of Auvergne, of the Sarraïmes of Dauphiné, of the Cretins of the Alps, and the gradual deterioration of the slave population of America, have been attributed to the consanguineous alliances which are unavoidable among these unfortunate peoples. More recently, the same opinion has been supported by the history of deaf-mutism and of idiocy. Of 233 deaf and dumb children whose parentage could be traced, 70, or nearly 30 per cent., were the offspring of the intermarriage of blood-relations. But in opposition to, and apparently destructive of such an hypothesis, may be adduced the unimpaired condition and symmetry of the Jews, of the small Mohammedan communities in India, of the isolated tribes in North America, among whom the repeated intermarriage of near relatives is compulsory. Moreover, this opinion does not hold in the analogous cases among the inferior animals, as the Arabs can trace the pedigree of their most valuable horses to the time of Mohammed, whilst they avoid all crossing; the stud-books in this country record the descendants of racers for 200 years, and show the perpetuation of the qualities of strength, and weight, and fleetness by propagation within the endowed family, both Eclipse and Childers being descended from a horse the offspring of a parent and foal; and the descendants, again, of these horses, which still maintain the highest estimation, afforded many instances of very close breeding; and lastly, the Durham ox and the Ditchley sheep were the result and triumph of breeding in and in. The present state of the controversy, as it has been recently conducted in France, may be summed up in the proposition, that consanguineous alliances are not necessarily hurtful to the offspring, provided the parents be healthy and robust; but the observations of Doyay and Benias in America show that such generalisations should be received with
INTERMEDIATE HARMONIES—INTERNATIONAL LAW.

cation. It should be added, that even were it established that mental disease generally followed such unions, the transmission might depend rather upon the increased certainty of reproducing hereditary tendencies, than upon the violation of any physiological law.—Steinau, Essay on Hereditary Diseases and Intermarriage; Devay, Du Dangers des Mariages Consanguins (1862); Boulin, Dangers des Mariages entre freres & sœurs; Annales d'Hygiène Publique, Juillet (1892).

INTERMEDIATE HARMONIES, in Music, are the harmonies introduced between extreme non-related keys, while modulating from the one key to the other, which harmonies prepare the ear to receive the new key.

INTERMEZZO, a short dramatic comic scene, with singing, peculiar to the Italian stage, and introduced between the acts of an opera or play.

INTERMITTENT FEVER. See AGUE.

INTERNATIONAL LAW is divided into public international law and private international law.

1. Public International Law, or the law of nations, consists of those rules which independent nations agree among themselves to be just and fair in regulating their dealings with each other in times of war and peace. The mode in which they arrive at this common understanding of what is right and wrong is by comparing the opinions of text-writers who profess to set forth and collect the general opinion of civilized nations, for all these writers appeal ultimately to the principles of natural reason and common sense, as the test of what they profess to be the proper rule. Treaties of peace, alliance, and commerce also define and modify the existing international law as between the contracting parties. The proceedings of prize-courts, which profess to proceed on principles of natural justice, of universal application, are also declarations of this international law. The leading doctrines thus adopted are as follows:

A sovereign state is one which governs itself independently of foreign powers. In the event of a civil war in one nation, other nations may remain indifferent spectators, and treat the ancient government as sovereign, and the government de facto as entitled to the rights of war against its enemy. If the foreign state profess neutrality, it is bound to allow impartially to both belligerent parties the free exercise of those rights which war gives to public enemies against each other, such as the right of blockade, and of capturing contraband and enemy goods, provided such state asserts its independence, and has shown its ability to maintain this independence, the recognition of its sovereignty by other foreign states is a question of policy and prudence only; but until acknowledged, courts of justice and private individuals are bound to consider the ancient state of things as remaining unaltered. When a change occurs in the person of the sovereign, or in the internal constitution of a state, all treaties made by such state which were not personal to the former sovereign, continue to be binding on the succeeding sovereign.

All sovereign states are, in the eye of international law, on a footing of equality. Each state has the right to look to the other states for the protection of its people for purposes of self-defence, and to develop all its resources in the manner it thinks fit, so long as it does not interfere with the same equal rights of other nations. When, however, its just and fair, or agrarian, or military, or naval forces beyond what all the other states consider proportioned to its position, then those other states have some ground to interfere. This, however, should be attempted rashly; and it is difficult to define what is a just ground of interference. The acquisition of colonies and dependencies has never been considered a just motive for such interference.

According to Wheaton (International Law, 88, 6th ed.), interferences to preserve the balance of power have been generally confined to prevent a sovereign, already powerful, from incorporating conquered provinces into his territory, or increasing a dictatorial influence over the government of other independent states. The aversion to interference has no doubt, in modern times, become stronger and stronger; and it may be taken to be now almost an axiom, that no foreign state has any just ground of interfering in what is merely an internal revolution of a state, or a mode of readjusting its own constitution; in short, each state ought to be allowed to manage its own internal affairs, and to choose whatever form of government best suits the people, for the exercise of this right can, in general, nowise affect other states.

Each state has the natural right to make its own laws regulating the property and status of all the subjects within its territory. On the high seas, both the public and private vessels of every nation are subject to the jurisdiction of the state to which they belong. Offences thereto committed against its own municipal laws give to the state to which the vessel belongs jurisdiction; but a violation of navigation and search belongs to a nation in time of peace, though piracy and other offences against the law of nations, being crimes not against any particular nation, but against all mankind, may be punished by any state in which the offenders can be apprehended. The traffic in slaves is, however, not classed with piracy by the law of nations, though nations may declare it to be so as regards their own subjects; and they may also enter into a compact, by which the slave trade has been done by Great Britain with other nations. With regard to crimes and their punishment, though each state will punish all crimes by whomsoever committed, if committed within its own territory, and also all crimes committed in its public and private vessels on the high seas, or in a foreign port; likewise all crimes, wherever committed, by one of its own subjects, yet it cannot arrest one of its own citizens if he is within the territory of another state; to do so would be an invasion of the municipal law of that state; hence it can only arrest its criminals in foreign states by the leave of such state, and such state is not bound to accede to such a request. Hence arises the expediency of two states entering into an agreement, by which they bind themselves to give up to each other criminals who have committed certain specified offences.

There are certain usages or ceremonial of respect shown by one nation to another in certain circumstances, and these are founded on the theory of the equality of sovereign states. As regards the right of precedence among kings, emperors, and princes, there is nothing settled and binding, except, perhaps, that Catholic powers concede the precedence to the pope. But as regards minor matters, it is the settled courtesy for one nation to salute by striking the flag or the sails, or by firing a certain number of guns on approaching a fleet, or a ship of war, or entering a fortified port or harbor. Sometimes these ceremonials are regulated by express treaty, as, for example, as regards the maritime honors exacted by Denmark from vessels passing the Sound and Belt at the entrance of the Baltic Sea.

The rights of states in time of peace consist of the rights of legislation and of negotiation. Every independent state has a right to point of view, to send public ministers or representatives...
INTERNATIONAL LAW.

To, and receive ministers from, any other sovereign state with which it desires to maintain relations of peace and amity. See AMBASSADOR; ENSOY; CHARGES D'AFFAIRES; CONSUL.

When war is commenced between two countries, there are certain rights acknowledged to exist towards each other. Before war is proclaimed, intermediate methods are sometimes adopted, with a view to avoid the calamities that last necessarily; these are laying an embargo on the ships or property of the offending state found in the territory of the offended state; also taking forcible possession of the ship, for purposes of exchange, also retaliating and making reprisals. When war is once declared, the first step is to seize and confiscate all the enemy's property within the territory. It becomes unlawful for the subjects of each belligerent state to trade with the subjects of the other belligerent. The test of whether a person is a subject of either state is generally his domicile; so the character of ships depends on the national character of the owner, as ascertained by his domicile. As regards the conduct of one belligerent state against the other, some writers have laid it down, that everything is fair against an enemy, and that no means of punishment are too severe; but this rigid rule has been qualified by the more humane practice of modern times. Instead of putting prisoners of war to death, the practice is to exchange or discharge them on conditions. Instead of indiscriminate destruction of the enemy's property, temples, public edifices, monuments of art and science, are spared. The laws of war are more applicable to sea than land; and not of the practice of commissioning privates to prey on the commerce of the enemy, the captain being in general entitled to the property. When property taken is recaptured by or on behalf of either side, it is the rule of dealing with the property recaptured. The validity of a capture at sea must be determined in a prize court of the captor's country or of an ally, and the prize court proceed to act on universal principles applicable to all countries.

As regards neutrals in time of war, the leading doctrines are stated under the heads CONTRABAND; BLOCKADE; FOREIGN ENLISTMENT ACT.

At the Congress of Paris, 1856, the ambassadors of Great Britain, France, Russia, Austria, Prussia, Turkey, and Sardinia, agreed to a joint declaration, modifying the state of the laws of war as follows:

1. To abolish privateering; 2. To adopt the maxim, 'free ships, free goods'—i.e., an enemy's goods aboard a neutral warship are not contraband of war; 3. To allow a neutral's goods in an enemy's ship to be free except as to contraband; 4. To abolish blockades unless they are real, and kept up by an effective force. These declarations were not acceded to by America, because it objected to the abolition of privateering, so that though, in the event of war between the countries which agreed in the declaration, the above modifications will probably be adopted, this will not be the case in the event of America being at war with one or other of these parties. See Wheaton's International Law; Mackenzie's Studies in Roman Law; Macqucr's Chief Points in the Laws of War.

The UNIVERSAL LAW OF PROPERTY is that collection of laws that regulates the mode in which ordinary courts of justice administer the remedies and give effect to the rights of parties where such rights were acquired either wholly or in part in foreign countries, and where different remedies must otherwise have necessarily applied. In such cases, the court which administers the remedy, acting on what is called the courtesy of nations, or comitas gentium, endeavours to meet the purposes of justice to the same extent as if they were still bound by the foreign laws, and gives effect to those laws so far as they do not conflict with the native laws in essential principles. The fundamental doctrine which underlies this branch of law is, that each subject of a foreign independent state is entitled to have the protection of his own laws, so far as is compatible with the equal independence of the state whose courts administer the remedy, and hence, a court can in general entertain a suit where the subject of the suit is a citizen of any pro hac vice, incorporate part of the foreign laws as part of its own remedies. Accordingly, in carrying out this doctrine, certain fair and equitable rules are adopted, in dealing with foreigners in certain situations, the chief of which arise out of the heads of marriage, death, intestacy, and remedies generally.

This branch of the law has been long cultivated by the continental countries of Europe; where many jurists have discussed its principles. But probably owing to the insular position of the United Kingdom, little attention was given to it there; and indeed no work even incidentally treated of the subject until Mr Justice Story, an American judge, in 1834, first produced his celebrated treatise on the Conflict of Laws, and gave to British lawyers a methodical view of the results at which foreign jurists had arrived. In the United States, where each independent state had its own municipal laws, and each was a sovereign country in its own right, and among other federal states, it was natural and inevitable that some system should be adopted as to the way each state should deal with the rights of persons coming from the neighbouring states; and hence the American Law of Conflicts. It is the result of this branch of the law. Story's work is still the standard authority in the United Kingdom. Since the laws of Scotland differ in many respects from those of England, the independent country, and that of its own courts exercising independent jurisdictes, it is a matter of course that questions of conflict under these two codes of law should often arise. Not only do the courts of Scotland and England differ in their practice and the manner of enforcing laws, and deal with each other in much the same way as they would deal with France or any other foreign country, but the laws in other respects are materially different, and give rise to conflicts. On the particular branch of law affecting England and Scotland, Mr Paterson's Compendium of English and Scotch Law contains a summary of all the material differences existing between the laws of these two countries, that are of the greatest practical importance.

As regards marriage, the leading doctrine of the comitas gentium is, that it is immaterial in what part of the world a man is married provided he is married, and when once married according to the law of the place where he then is, each marriage will be held a valid marriage all the world over, and wherever he goes. This doctrine, however, is qualified in this way, that the lex loci contractus—i.e., the law of the place where the marriage was contracted—shall regulate the validity of the marriage only so far as any ceremony is essential to the institution of marriage; but it is not allowed to dictate who the parties are, or the cause of marriage, nor the essential part of the contract. The reason of the latter qualification is, that there may be rules of policy in one country which may prohibit marriage to be entered into from those of another country, or of certain consequences, and therefore the evasion of the native law by persons going abroad for such a purpose is not to be tolerated. For example, in Scotland, marriage is treated as a mere contract, and can only be created by mutual consent; while in England some ceremony...
INTERPLEADER SUIT—INTERVAL

is absolutely essential—viz., the ceremony of the marriage. If a Scotchman, and not the English law, presides, or in a superintendent-registrar's office, if there is no priest. Accordingly, any two English persons may go to Scotland, and be married there by exchanging a mutual declaration of marriage, and they may immediately return to England, and will be there and everywhere else held to be married persons. On the other hand, if two Scotch persons go to England, they cannot be married by exchanging mere verbal declarations; they must be married, according to the English law, either by a priest in a church, or without one in a superintendent-registrar's office; and if so, they will be held to be married all the world over. Again, the law of England declares that no marriage shall be valid within certain prohibited degrees, and amongst others no man is there allowed to marry his deceased wife's sister. Hence, if a man and his deceased wife's sister go from England to Denmark, where the law allows such persons to marry, and they are there married, according to the Danish law, their marriage will prevail, and return to England, where their domicile is, they will not be treated as married persons, because they went to evade this rule of law in another country. According to the English law, mere form is vital importance. It would, however, be different if a man and his deceased wife's sister, who were Danes, and domiciled in Denmark at the time of their marriage, came afterwards to this country; the law of Denmark is that a man and his deceased wife's sister, if properly married, for their domicile was then Danish, and they had a right to follow their own law. Another important head of international law is as to the law which regulates the succession to the property of a deceased person, which, however, has hitherto been successfully opposed in parliament, on the ground that so great a facility of pursing a debtor may be abused. INTERPLEADER SUIT is a suit brought in the Court of Chancery in England or Ireland to determine which of several parties claiming the same thing is entitled. Formerly, there was no analogous process in courts of common law whereby several parties claiming one thing could be brought into the field to contest their claims, but in 1821 a statute gave power to do this to a limited extent. The corresponding process in the law of Scotland is an action of Multiplying (q. v.). INTERPOLATION, the insertion of a word, line, verse, sentence, part of a sentence, or whole passage, generally with a view to secure respect for some opinion by the apparent support of antiquity, or of those whose authority is greatest. Many instances of interpolation are well known, and others are with great probability suspected, in which the works of early Christian writers have been tampered with, to make them yield support to novel doctrines and practices.—In mathematics, interpolation is the insertion between two members of a series increasing according to a certain law, of other members such as, if not absolutely, yet very nearly, may accord with the same law. INTERVAL, in Music, is the difference of pitch between sounds in respect to height or depth, or the distance on the staff from one note to another, in opposition to the unison, which is two sounds exactly of the same pitch. From the nature of our system of musical notation, which is on five lines and the four intervening spaces, and from the notes of the scale being named by the first seven letters of the alphabet, with repetitions in every octave, it follows that there can only be six different intervals in the natural diapason, and the unison be attained. To reckon from C upwards, we find the following intervals; thus, C to D is a
INTESTACY—INTOXICATION.

second; C to E is a third; C to F is a fourth; C to G, a fifth; C to A, a sixth; C to B, a seventh; and from C to C is the octave, or the beginning of a similar series. Intervals above the octave are therefore merely a repetition of those an octave lower; thus from C to D, above the octave, although sometimes necessarily called a ninth, is neither more nor less than the same interval which, at an octave lower, is termed the second. A flat or a sharp placed before either of the notes of an interval does not alter the name of the interval, although it affects its quality; for example, from C to G♯ is still a fifth, notwithstanding that the G is raised a semitone by the sharp. Intervals are classified as Perfect, Major, and Minor. Perfect intervals are those which admit of no change whatever without destroying their consonance; these are the fourth, fifth, and the octave. Intervals which admit of being raised or lowered a semitone, and are still consonant, are distinguished by the term Major or Minor, according as the notes of the interval are in the proportion of 5 to 4; when the E is lowered a semitone by a flat, the interval is diminished a fourth, or consonant, but in the proportion of 6 to 5, and is called a minor third. The same description applies to the interval of the sixth from C to A, and from C to A flat. The second and seventh, though reckoned as dissonances, are also distinguished as major and minor. The terms 'extreme sharp' and 'diminished' are applied to intervals when they are still further elevated or depressed by a sharp or a flat. For the mathematical proportions of intervals, see HARMONICS.

INTESTACY, the state of a person who has died without leaving a will. Every person in the United Kingdom has the right, as one of the incidents of ownership, of regulating the succession of his property after his death; that is, of executing a will which must comply with certain requisites, so as to show that it was solemnly and deliberately made, by which will the owner can give his property to whomsoever he pleases. The forms in Scotland differ from those in England and Ireland, and there is some restriction on the right of testing or bequeathing property, but in all places the principle is, that if no will, or deed equivalent to a will, is executed, or, if a will executed is illegal or defective in form, then an intestacy occurs, and the law provides an heir or next of kin, in lieu of the owner himself doing so. See Heir; Succession; Will. A person may die partially intestate, for his will may have included only some of his property, in which case the property not so included goes to the heir-at-law, or next of kin, according as it is real or personal estate, as if no will had been made. But it is often a difficult question in construing the will, whether the property in question is included, or was not conveyed by general words to the residuary legatees or devisees—a question which turns entirely on the language used in each case.

INTESTINES. See Digestion, Organs and Process of.

INTONING, the generic term used of the word, is the recitative form of offering prayer. Intoning differs from ordinary reading in having fewer inflections of the voice, and these only at stated parts of the prayers, and according to certain rules. The greater part of the prayers are recited on one note; this is called the root or the declivity being sung to the proximate notes of the scale. In the longer prayers, the terminal inflection is generally omitted. The words Intoning and Chanting are sometimes used interchangeably, but, though there is ground common to both, each has a domain peculiar to itself. Intoning may be defined as ecclesiastical recitative, and when several voices are employed in its performance, they are for the most part, in unison, breaking into harmony at the termination of the clause or sentence. Chanting embraces recitative and rhythm, both divisions being in continuous harmony. In the Anglican service, as performed in cathedral churches, all those words of the service which are not set to rhymed music, are intoned; these embrace that part of the morning and evening service which precedes the daily psalms, the litanies, and the prayers in general.

John Marbeck (1550) was the first in England to adapt the offices of the reformed church to music; his work contained melody only. He was followed by Thomas Tallis, who flourished during the reigns of Henry VIII., Edward VI., Mary, and Elizabeth. The grave melody (found on the ancient usage) and sublime harmonies of Tallis have never been equalled, and have continued in use till the present day with but slight modification. Tallis seems to have written in various forms of the Gregorian chant, the principal of which are the plainsong or mode of plainchant. The plainsong or plainsong form is, to the stage now used for the psalms. In the Roman Catholic Church these are sung to the Gregorian tones. See GREGORIAN CHANT. The canticles are sung to rhythmical music of a more elaborated character, in which they are technically ' plainsong chants.' The lessons, previous to the last review (1691) of the Book of Common Prayer, were intoned; since then, the invariable practice has been to read them.

The practice of intoning existed among the Jews at a very early period, and there is great probability that the ecclesiastical chant in present use throughout Christendom is but a modification of that which formed part of the ancient Jewish ritual. The eastern and western churches, at variance on most points, are at one on this. Mohammedans also make use of this mode of prayer; and barbarous tribes (American Indians and South Sea Islanders) are wont to precipitate their false god into a species of rude chant; all which seems to point to some deeply seated instinct of human nature, and to indicate an intuitive perception of the truth, that a solemn and reverential manner, distinct from his manner of ordinary intercourse with his fellows, best befits the creature in his approaches to the Creator. The Lutheran Church and the Church of England have continued the practice, though only to a perfunctory and non-essential extent. The latter uses it in her conventual and collegiate churches, and in these vast edifices its advantages over reading are strikingly manifest.

INTOXICATION. Whether induced by fermented liquors or by distillates spirits, it is through the alcohol contained in either that the effects of intoxication ensue. These may be considered under two heads: 1. As they immediately manifest themselves during a single act of intoxication; and, 2. As they gradually arise through the frequent repetition of such an act. The one refers to the state of drunkenness simply, the other to the habit (Intemperance).

The effects of alcohol, in a single act of intoxication, vary according to the way in which the spirit is swallowed. If swallowed in a great quantity, it acts on the organism in large quantities or in a concentrated form, the agency is that of a powerful narcotic poison. The mode of action here is partly through a direct depression by the alcohol on the nerves of the stomach, and partly by its absorption into the blood, and its transmission thus to the brain, which is proved to take place with great rapidity. The individual falls into a deep stupor, from which a
HUNGER, this is often liable to those minor illusions which end in the full development of what is known as the drunkard's delirium, or delirium tremens, a form of temporary insanity characterised by a state of abject terror, with shaking of the limbs, the sufferer fancying that he is surrounded by a herd of demons, and that he is devoted otherwise to horrors, disasters, or crimes. One effect, and a leading one, of the customary presence of alcohol in the blood of the drinker, is to reduce the vitality of that fluid, so that it tends to sustain only the lowest forms of nutrition and animalisation, and deposits, in great part, merely an inert fat within those organs where it should minister to the growth and maintenance of a delicate construction, destined for use of potential to life. Thus we have fatty deposits, changes of higher structures into fat, in the heart, the liver, and in the blood-vessels, the coats of the last becoming easily ruptured. Hence, liability to diseases of the heart and of the liver often followed by dropsies, or to affections of the other intestines, or to attacks of apoplexy and palsy. If not cut off abruptly in his career, the life of the drunkard becomes one long malady towards its close, the final condition of those who are plunged in this mind and body, yet with threes of suffering to the last. It has been authoritatively shown that, while the average expectation of future life to the temperate man at fifty may be reckoned at twenty years, that of the drunkard at the same age is only four years. Again, between the ages of twenty-one and thirty, the deaths among drunkards have been found to be more than five times, and between thirty-one and fifty, more than four times the proportion of those occurring among the general community at the like ages.

INTOXICATION, or DRUNKENNESS, is, in point of law, no excuse for any wrong done by the drunken party. Crimes which are committed in a state of drunkenness are punishable in the same way as if the actor were sober, though it is discretionary in the court to mitigate the sentence. As regards contracts entered into by a drunken party, there is no peculiarly, unless the fact of drunkenness was taken advantage of by the sober party, in which case it lies on the drunken party to prove this. Cases may no doubt arise where the drunkenness may be an element of fraud, and so the contract or some part of it may be avoided. The state of drunkenness, when privately indulged in, is not an offence against the law; but if it be shown publicly, it may become so. If, for example, a person be drunk in the streets or a public place, he was made, by a statute of James I., liable to be fined 5s., or, if unable to pay, to be committed to the stocks for six hours. By a more modern enactment of 1890, called the Refreshment Houses Act, 23 Vict. c. 27, every person found drunk in any street or public thoroughfare, and who, while drunk, is guilty of riotous or indecent behaviour, incurs a penalty of 40s.; and if a person is drunk, riotous, quarrelsome, or disorderly in any public-house, beer-house, or refreshment-house, and refuses to leave the premises on request, he incurs a penalty of 40s. The above enactments are of general application in England, but there are also similar enactments in many local improvement and police acts regulating large cities. In Scotland, several acts exist passed against drunkenness, which, however, are in desuetude. In several local police acts, a penalty is imposed on drunkenness in the streets, and the Police and Improvement Act of Scotland, 25 and 26 Vict. c. 101, s. 214, subjects drunken persons in the streets to a penalty of 40s., or 14 days' imprisonment, in all places where that act is adopted.
INTRODUCTION, in a general sense, is any work, consisting of not less than a parapet and a ditch, which fortifies a post against the attack of an enemy. As a means of prolonging the defence in a regular work of permanent fortification, intrenchments are made in various parts, to which the defenders successively retire when driven in from forward works. Bastions are ordinarily intrenched at the gorge by a breastwork and ditch, forming either a re-entering angle or a small front of fortification. Such a work across the gorge of the Redan at Sebastopol caused the repulse of the British attack in September 1855. A cavalier, with a ditch, is also an intrenchment. An army in the field often strengthens its position by intrenchments, as by a continued line of parapet and ditch, broken into redans and curtails, or by a line with intervals, consisting of detached works of more or less pretension flanking each other.

INTRODUCTION (Ital. introduzione), in Music, is a kind of preface or prelude to a following movement. Formerly, the introduction was only to be found in large musical works, such as symphonies, overtures, oratorios, &c.; but now it is found in every rondò, fantasia, polonaise, waltz, &c., on the principle that it is considered abrupt to begin all at once, without preparing the audience for what is to come. In a stricter sense, introduction is applied to the piece of music with which an opera begins, and which immediately follows the overture. In some cases, the overture and introduction are united, the composition going on without any formal pause, as in Gluck's Iphigénie en Tauride, Mozart's Idomeneo and Don Giovanni. As the overture, which contains a harmonical sketch of the opera, should make a permanent impression on the audience, the custom of uniting it with the introduction has very properly been discontinued, and the introduction treated as an independent movement.

INTROMISSION, in Scotch Law, is the assumption of legal authority to deal with another's property. It is divided into legal and vicious. Legal intromission is where the party is expressly or implicitly authorised, either by adjudgment or deed, to interfere, as by drawing the rents or getting into the premises; whereas vicious intromission arises where an heir or next of kin, without any authority, interferes with a deceased person's estate; as, for example, where a person not named by a will, or without the authority of any will, collects the property of the deceased person, as if he were regularly appointed. By so doing, the vicious intromitter incurs the responsibility of paying all the debts of the deceased. The vicious, however, may be taken off by the intromitter being regularly confirmed executor. The corresponding phrase in England is a vicious intromitter is an executor de son tort.

INTRUSION, the Scotch law-term for a trespass on lands.

INTUITION. See INSTINCT, and COMMON SENSE.

INTUS-SUSCEPTION, or INVAGINATION, is the term applied to that partial displacement of the bowel in which one portion of it passes into the portion immediately adjacent to it, just as one part of the finger of a glove is sometimes pulled into an adjacent part in the act of withdrawing the hand. In this case, the contained portion of intestine is liable to be nipped and strangled by the portion which contains it, and all the danger of Hernia (q.v.) results, with far less chance of successful interference on the part of the surgeon or physician. It is one of the most frequent and fatal causes of obstruction of the bowels. The extent of the intus-susception may vary from a few lines to a foot or more. Even when inflammation is set up, the affection, although in the highest degree perilous, is not of necessity fatal. The invaginated portion mortifies and sloughs, while adhesion is established between the peritoneal surfaces of the upper and lower portions at their place of junction, so that the continuity of the tube is preserved, although a large portion may be destroyed. If the patient is strong enough to bear the shock of the inflammation, gangrene, sloughing, &c., a complete recovery ensues.

INVULIN. See Elecampane.

INWUS, or INNUUS, a genus of apes, to which the Barbary Ape (q. v.) belongs. The Barbary Ape is I. sphyrius.

INVALIDES, wounded veterans of the French army, maintained at the expense of the state. The Hôtel des Invalides is an establishment in Paris where a number of these old soldiers are quartered. Its chapel contains the tomb of the Great Napoléon, and is an object of much attraction to all visitors.

It was founded by Louis XIV. in 1671, and during his reign, and for a long time afterwards, was a place of retirement for the aged servants of court favours as well as for invalided soldiers; but this abuse was put an end to by St Germain in Louis XV.'s reign. In 1789, the Hôtel had a revenue of £68,000, but during the time of the Republic its property was alienated, and the institution supported from the public revenue. The Hôtel can accommodate 5000 men, and the actual number of inmates is not much below this.

INVALIDING signifies the return home, or to a more healthy climate, of soldiers or sailors whom wounds or the severity of foreign service has rendered incapable of active duty. The man
INSTRUCTIONS—INVERNESS-SHIRE.

invariable returns to his duty as soon as his restored health justifies the step.

INVERSIBLE PLANE. The position of a point in space is determined—as explained in the article CO-ORDINATES—by referring it to planes intersecting in another at right angles; and in ascertaining the motion of the point by this means, the planes must either be immovable, or allowance must be made for their altered position, an operation of considerable complexity. In astronomy, none of the objects unfixed planes, and instead of the Equator (q.v.) or of the Equator (q.v.), possesses this requisite quality of fixity so as to form a convenient basis for determining the position of heavenly bodies with absolute exactness. Lapse, therefore, conferred a boon on astronomy, when he discovered that, in the solar system, there does exist an invariable plane, about which the orbits perpetually oscillate, deviating from it only to a very small extent on either side. This plane passes through the centre of gravity of the solar system, and it is so situated, that if all the planets be projected on it, and if the mass of each planet be multiplied into the area, corresponding to any given time, which is indicated by the projected line of vector, the sum of such products will be a maximum. By means of this property, which is independent of any particular epoch, it will be easy for astronomers in future ages to determine the exact position of the plane, and to compare observations together by means of it. (Grant's History of Physical Astronomy.) Such a plane is not peculiar to the solar system, but must exist in all systems where the bodies are acted on by other forces than their mutual attraction. See FORCE.

INVECTA ET ILLA TA, a phrase used in Scotch law to denote all things which a tenant has brought upon the premises, as his household furniture, tools, utensils, &c.; also, in case of thralldom, all corn brought within the limits of the third or servitude.

INVECTED, or INVECKED. See ENGRAINED.

INVENTION. See PATENT.

INVENTORY, a list or schedule of goods or property setting forth the particulars, so as to inform parties interested. The term is used in England in reference to an executor or administrator making out a list of the deceased person's effects. In Scotland, it is also used in reference to the property of an infant, pupil, or minor, whose estate is under the care of a guardian, tutor, curator, judicial factor. In Scotland, it is also used in connection with the various pleadings and deeds and documents produced or used in a suit or action, then called an inventory of process. So as to an inventory of titles, that is, the titles of an estate shown to a purchaser.

INVERARAY, a small royal and parliamentary burgh and seaport of Scotland, the county town of Argyll-shire, is picturesquely situated on the west shore of Loch Fyne, where the river Aray falls into the loch, 45 miles north-west of Glasgow. It consists of one principal street running parallel to the loch, and a square with a church in the centre. An obelisk, standing near the church, commemorates the death of 17 gentlemen, all Campbell's, who were executed here without trial in 1665, for their adherence to the Covenant. Close by the town stands Inveraray Castle, the chief residence of the Dukes of Argyll. I, the ancient town, the capital of the West Highlands, was situated at some distance to the north of the present town. Not a vestige of it now remains. The trade of I. is chiefly in herring-fishing. Pop. (1861) 1075.

INVERCARGILL, the second in population, as Dunedin is the first, among the settlements of the province of Otago, in New Zealand, stands on the south-east coast of the Middle Island. It has received 117 immigrants, all from the Australian colonies; imported to the value of £36,679, exported to the amount of £3,345, and paid of customs-duties, £301, 16s. 5d. The corresponding returns for 1859 had been 365 immigrants, £23,926 of imports, £2,142 of exports, and £4,093, 8s. 9d. of customs-duties.

INVERNESS, a royal, parliamentary, and municipal burgh, situated at the mouth, and mostly on the right bank, of the river Ness. It is the chief town of the county to which it gives name, and may be regarded as the capital of the Highlands. Its environs, well cultivated and beautifully wooded, are almost surrounded by mountains and hills of various heights, forming altogether a most picturesque and interesting landscape. Pop. (1861) 12,509; annual value of real property, £33,166; corporation revenue, £2,100 a year. It unites with Fortrose, Nairn, and Forres, in returning one member to parliament. The first charters of I. date from 1165—1214 A.D. By one of these, it is stipulated that when the king has made a ditch round the burgh, the burgesses shall make a palaide on the edge of the ditch, and keep it in good repair for ever. In 1189, at a council called by Donald, Lord of the Isles, on his way to Harlaw (q.v.), Macnab, writing of the year 1609, describes I. as 'a Saxo colony among the Celts, a hive of traders and artisans, the metropolis of a population of loungers and plunderers, a solitary outpost of civilisation in a region of barbarians.' The Castlehill, on the south side of the town, part of an old sea-terrace, was the site of a castle, which, in 1303, was taken by the adherents of Edward I. of England, but subsequently retaken by those of King Robert Bruce. King James I. is said to have held a parliament in the castle in 1427. An iron suspension-brIDGE, constructed in 1854, connects the two parts of the town. In the High Street stand the town-hall, and Exchange; and on the road to Edinburgh, by Donaldson, is the famous Clach-na-cuddin, a lozenge-shaped blue slab, formerly regarded as the palladium of the burgh. In the same street, are the Town-hall and the Mechanics' Institute and library, several printing establishments, two newspapers, a native bank (the Caledonian), and five other banking-offices. I. has still its four great annual fairs, but the establishment of shops throughout the county has greatly diminished their importance. It has three harbours, built at different times, and a considerable amount of shipping by the Moray Firth and the Caledonian Canal. Insize 12509.

INVERNESS-SHIRE, the largest county of Scotland, includes Badenoch, Glenroy, and the valley of the Spey on the east; Lochaber on the
INVERTEBRATE ANIMALS—INVESTITURE

south; Glenelg, Glen Garry, Arisaig, Moydart, and Frasers' County on the west; Glen Urquhart and Glen Moriston towards the centre. It includes also Strathglass on the north; and several of the western islands, viz., Skye, Harris, North and South Uist, and Barra, &c. The mainland portion lies between N. lat. 56° 40' and 57° 56', and W. long. 3° 30' and 5° 55'; and is bounded on the E. by the counties of Aberdeen, Banff, Elgin, and Nairn; on the S. by Perth and Angus-shire; on the N. by the Atlantic and Bencounich; and on the N. by Ross-shire. It measures from north-east to south-west 85 miles, and from north-west to south-east 57 miles; and has an area of 4256 square miles, of which more than two-thirds consist of barren heath. The wildest and most mountainous portion is towards the west, comprising a tract 70 miles in extent, and designated the Rough Bounds. The most extensive moss in Great Britain lies on the south of Badenoch, where, in the naturally formed wooded islands, large herds of deer find a refuge. These mosses had at one time been mostly, if not wholly, covered with trees, some of them of great magnitude. In Strathpey, three tiers of stocks, one above another, have been found, showing that a succession of forest trees must have grown up, flourished for ages, and then, one after another, disappeared by the work of time or the axe. At present, the natural pines occupy a larger space in this and other counties of Britain. There are also many thousand acres of plantations by ordinary forest trees. Some mountains attain considerable altitude. Ben Nevis, now ascertained to be the highest in Great Britain, is 4406 feet above the level of the sea. Caingorm, partly in this county, is 4053 feet high. The geological formation of the county is various; but primary rocks consisting of gneiss, mica-slate, granite, porphyry, and trap rocks, mostly prevail. The most fertile soil of this county rests on the red sandstone in the valley of the Aird, and between the county town and Beauly. There are several lakes of some extent, as Loch Ness, Loch Loych, Loch Laggan, Loch Ericht, and a number of other lochs forming bays of the sea. The principal rivers are the Ness, Spey, Nairn, and Morays, and the Foyers (q. v.). The county is divided among 80 or 90 proprietors, a few of whom possess 1000 acres of surface. The old valued rent was £6999; the valuation for 1839—1855 £224,258. The assessment on the land for all county purposes amounts to £5500.

According to the last agricultural statistics, taken by the Highland and Agricultural Society, for crop and year 1837, the total acreage under rotation of crops formed the principal 42,920, of which there were 1980 acres of wheat, 2341 acres of barley, and 13,749 acres of oats, averaging respectively 24, 29, and 29s. bushels per acre. Of green crops there were 5842 acres of turnips, and 3070 of potatoes, averaging respectively 12 tons 17 cwt. and 2 tons 7cwt. per acre. Of live stock, there were 3741 horses, 23,209 cattle, 452,705 sheep, and 1706 swine. There are comparatively few antiquities worth noting in the county. These consist principally of remains of vitrified forts and ruins of old castles. The battle which decided the fate of the Stuarts was fought 16th April 1746, on Culloden Moor, a few miles from Inverness.

The Gairloch mountains are still covered with snow in winter, but is scarcely any district exclusively, spoken. Pop. 88,888.

The constituency, which numbers 955, returns one member to parliament.

INVERSION, in Music, is the transposing of one of the two notes of an interval by an octave or downwards, to a position the reverse of that which it before occupied with respect to the other note, so that if the transposed note was the lower note of the two, it shall now be the higher one, and vice versa. The new interval thus takes its name from the complement of the octave; for example, a unison inverted becomes an octave, a second becomes a seventh, a third becomes a sixth, a fourth becomes a fifth, a fifth becomes a fourth, a sixth becomes a third, a seventh becomes a second, and an octave becomes a unison. The following shews how these arise:

<table>
<thead>
<tr>
<th>Unison</th>
<th>2d</th>
<th>3d</th>
<th>4th</th>
<th>5th</th>
<th>6th</th>
<th>7th</th>
</tr>
</thead>
<tbody>
<tr>
<td>Union.</td>
<td>5v</td>
<td>7v</td>
<td>6th</td>
<td>5th</td>
<td>4th</td>
<td>3d</td>
</tr>
</tbody>
</table>

By inversion diminished intervals become augmented, and augmented become diminished; major become minor, and minor become major; but perfect intervals are also perfect when inverted. For inversion of chords, see CHORD. An important use is also made of the word inversion, in reference to a whole passage or phrase, for which see DOUBLE COUNTERTOPOINr.

INVERTEBRATE ANIMALS (Invertebrata) are those animals which have not a vertebral column or spine. The division of animals into Vertebrate and Invertebrate is a natural and unavoidable one, acknowledged in all systems of zoology. But these groups being formed, the one on a positive, and the other on a negative character, are by no means of equal value in the classification of the animal kingdom. In Cuvier's system, the invertebrate animals form three of the great divisions of the animal kingdom—viz., Mollusca, Articulata, and Radiata, each of which, like Vertebrata, exhibits a peculiar type of structure. There are also animals of lower organisation than these which can with certainty be referred to these divisions, although included by Cuvier amongst the Radiata, forming the Aриа and Protocoа of recent systems. Amongst the lower invertebrate animals, much more than amongst vertebrate animals, the arrangement into groups must be regarded as at present, in a great measure, tentative and provisional; although in the higher departments of invertebrate zoology many of the classes and other groups are very well defined. The organisation of some of them, as Insects, however different from that of vertebrate animals, is not evidently lower, but exhibits a perfection as admirable as in any of them, whilst all vital powers are most fully displayed.

INVESTITURE (Lat. in, and vestro, to clothe, in feudal and ecclesiastical history, means the act of giving corporal possession of a manor, office, or benefice, accompanied by a certain ceremonial, such as the delivery of a branch, a banner, or an instrument of office, or less designed to signify the power or authority which it is supposed to convey. The contest about ecclesiastical investitures is so interwoven with the whole course of medieval history, that a brief account of its origin and nature is indispensable to a right understanding of many of the most important events of that period. The system of feudal tenure had become so universal that it affected even the land held by ecclesiastics, and attached to most of the higher ecclesiastical dignities, monastic as well as secular.
INVESTITURE—I INVOCATION OF ANGELS AND SAINTS.

ecclesiastics who, in virtue of the ecclesiastical office which they held, came into possession of the lands attached to such offices, began to be regarded as becoming by the very fact feudatory to the suzerain of these lands; and, as not unnatural result, the suzerains thought themselves entitled to claim, in reference to these personages, the same rights which they enjoyed over the other feudatories of their domains. Among these rights was that of granting the investiture to the bishops, abbots, and other church dignitaries, the form of investiture consisted in the delivery of a pastoral staff or crosier, and the placing a ring upon the finger; and as these badges of office were emblematic—the one of the spiritual care of souls, the other of the episcopal, as it were, between the pastor and his church or monastery—the assumption of this right by the lay suzerains became a subject of violent contention, and complaint on the part of the church. On the part of the suzerains it was replied, that they did not claim to grant by this rite the spiritual powers of the office, their function being solely to grant possession of its temporalities, and of the revenues derived from them. Nevertheless, the party urged, that the ceremonial in itself involved the granting of spiritual powers; insomuch that in order to prevent the clergy from electing to a see when vacant, it was the practice of the emperors to deny to the Roman, the Guy, the priest, until it should be their own pleasure to grant investiture to their favourites. The disfavour in which the practice had long been held found its most energetic expression in the person of Gregory VII., who held under him by his ordinary feudal tenure, and who urged, that the ceremonial were precedents for the repression of simony, had, in 1075, to condemn, under excommunication, the practice of investiture, as almost necessarily connected with simony, or leading to it. This prohibition, however, as is observed by Mosheim (II. 326), only regarded investiture in the objectionable form in which it was then practised, or investiture of whatever form, when the office had been attached to temporalities. But a pope of the same century, Urban II., went further, and (1095) absolutely and entirely forbade, not alone lay investiture, but the taking of an oath of fealty to a lay suzerain by an ecclesiastic, even though holding under him by his ordinary feudal tenure. The contest continued during the most of the 11th century. In the beginning of the 12th c., it assumed a new form, the pope, Pascal II., having actually agreed to surrender all the possessions and royalties with which the church had been endued, and which alone formed the pretext of the claim to investiture on the part of the emperor, on condition of the emperor (Henry V.) giving up that claim to investiture. This treaty, however, never had any practical effect; nor was the contest finally adjusted until the celebrated concordat of Worms in 1122, in which the emperor agreed to give up the form of investiture with the ring and pastoral staff, to grant to the clergy the right of election, and to restore all the possessions of the church of Rome which had been seized either by himself or by his father; while the pope, on his part, consented that the elections should be held in the presence of the emperor, who having invested, the pope should consecrate them to the provincial synod; that investiture might be given by the emperor, but only by the touch of the sceptre; and that the bishops and other church dignitaries should faithfully discharge all the feudal duties which belonged to their principalities.

Such was the compact entered into between the contending parties, and for a time it had considerable effect in restraining one class of abuses; but it went only a little way towards eradicating the real evil of simony and corrupt promotion of unworthy candidates for church dignities. Still the principle upon which the opposition to investiture was founded was almost a necessary part of the medieval system, and Mosheim (ii. 297) regards it as 'perfectly accordant with the religious principles of the age.' It was, in fact, but one of the many forms in which the spirit of churchmanship has arrayed itself, whether in ancient or modern times, against what they called the Episcopal system, of which never fail to develop themselves under the shadow of a state church, no matter what may be its creed or its constitution.

INVESTITURE, the term used in Scotch law to denote the giving feudal possession of heritable property. It was formerly given to the vassal in presence of the pars curiae, but latterly has been superseded by infeftment or sasine, and now it is effected by mere registration of the deed of conveyance.

INVOCATION OF ANGELS AND SAINTS, the act of addressing prayers to the blessed spirits, whether in general, or for the assistance of the just who have been admitted to the happiness of heaven. The practice of addressing prayers to angels, especially to the angel-guardian, to the Virgin Mary, and to other saints, prevails in the whole of the Roman Catholic, the Eastern, and the Anglican churches of all the various rites. In the Christian religion, the principle of the unity of God excludes all idea of subordinate sharers of the divine nature, such as is to be found in pantheism, and all alike, in Roman Catholicism as well as Protestantism, deny that its very principles exclude the idea of rendering divine worship, no matter how it may be modified, to any other than the One Infinite Being. But while Protestants carry this principle so far as to exclude every species of religious worship and every form of invocation addressed to angels or saints, as tending upon God's honour, and irreconcilable with the Scriptures, which hold Him forth as the sole object of worship and the only fountain of man's salvation, Roman Catholic religion permits and sanctions a worship (called douleia) of the saints, inferior to the supreme worship (latreia) offered to God, and an invocation of the saints, not for the purpose of grace from them, but to implore their assistance in matters of temporal concern, but in order to ask their prayers or intercession with God on our behalf. For this doctrine and the analogous practice, they do not advance the direct authority of Scripture (except a few passages which seem to them to imply the intercommunication of the two worlds, as Matt. xiii. 3, Luke xiv. 17, Exod. xxxii. 13), but rely on what to them is equally decisive testimony, viz., the unwritten word of God conveyed by tradition. Origem (Opp. ii. p. 273) speaks of the belief that 'the saints assist us by their prayers' as a doctrine which is 'doubted by no one.' St Cyprian, addressing the confessors going to martyrdom, engages by anticipation their prayers in his behalf (p. 41) that they shall have received their heavenly crown (Ep. 60, Dodwell's edition). To the same effect are cited the testimonies of Basil (Opp. ii. 133), Gregory Nazianzen (Opp. i. 258), Gregory of Nyssa (i. 1017), Ambrose (ii. 206), Chrysostom (iv. 449), and others, of the Fathers, and also the liturgies of the various ancient churches, whether of the Roman, the Greek, the Syrian, or the Egyptian rite.

On the other hand, Protestant historians, even admitting the full force of these testimonies to the existence of the practice, allege that the practice is an early, but unscriptural addition, dating only from the infusion into the church system of Alexandrian Neo-platonism and Oriental Magianism,
which they believe to have left traces even in the so-called orthodox Christianity of the fourth and fifth centuries. But leaving aside the doctrinal controversy, the fact at least is certain, that in the fourth, and still more in the fifth and following centuries, the usage was universal; and a curious evidence of its prevalence is furnished by the fact, that the very excess to which it was carried, was condemned by the Latins (that is, the Collyriants) by those who themselves confessed the lawfulness of the practice when confined within its legitimate limits. That similar excesses in the practice, and similar abuses with respect to nature and limits of the practice, in the invocation of the saints continued through the medieval period, Roman Catholics themselves admit, although they allege that such abuses were at all times repudiated by the authentic teachings of the Church, and the multiplied devo-
tions to the saints, especially to the Blessed Virgin, the efficacy claimed for them, and the extraordinary legends connected with them, and the prominence which the worship had assumed in the church, were among the materials of invective with which the first Reformers. The Council of Trent (25th Sess., On the Invocation of Saints) defines very precisely what is the doctrine of the Catholic Church on this subject. It declares "that the saints who reign with God suffer up their graces to God for men; that it is good and useful suppliantly to invoke them, and to resort to their prayers, aid, and help, for the purpose of obtaining benefits of God through his son Jesus Christ our Lord, who alone is our Redeemer and Saviour." From this decree it is inferred that the Catholic doctrine on the saints does not prescribe the practice of invoking them as necessary or essential, but only as "good and useful, and that their prayer of them is not the legitimate bestowal of grace and mercy, as from themselves, but only their prayers, their assistance, and their help in obtaining benefits from God; and although many forms of prayer which are in use among Catholics bear, especially to a Protestant reader, all the appearance of direct appeals to the saints themselves for the benefits which are implored, yet all Catholic authorities are unanimous in declaring that these forms of words are to be interpreted, and that, from habitual use, they are so interpreted, even by the most superficially instructed Catholics, with the understood explanation, that all the power of the saints to assist us consists exclusively in their prayers for us, and seconding our prayers: See Bellarmine, Contr. Controversarum, artist. i. cap. xvii.

Protestants object to the invocation of saints and of angels, that it is without evidence of divine authority, contrary to the whole tenor of Scripture, and derogatory to the mediatorial worship of Christ. They ask what reason can be adduced for believing that prayers addressed to saints are even heard by them, or that they have always a knowledge of the worship addressed to them? They further deny that the prayers addressed to saints—and particularly to the Virgin Mary—are always capable of explanation as merely an asking of their prayers on behalf of those who invoke them, and quote many instances in proof.

INVOICE. A list or account of merchandise or goods sold, either sent along with the goods them-
selves or separately.

INVOLUCR'ERE (Lat. a wrapper or envelope), in Botany, is a group of bracts surrounding flowers in their unexpanded state, and occupying a place on the floral axis beneath them after their expansion. The bracts which form an involucre are generally grouped in a whorl. In umbelliferous flowers, there is very commonly an involucre, not only to the umbel, but to each division of the umbel, or umbel-
tule. The former is called the general involucre, or simply the involucre; the latter are partial involucres, or involucelles. The cup of the acorn, hazel, chestnut, &c., may be regarded as an involucre.

INVOLUTE. See Evolute.

INVOLUTION AND EVOLUTION are two operations the converse of each other. The object of the first is to raise a number to any power, which is effected by continuously multiplying the number by itself till the number designated the power, thus, 2 raised to the third power is $2 \times 2 \times 2$; or 8; 7 raised to the fourth power is $7 \times 7 \times 7 \times 7$; or 2401, &c. Evolution, on the other hand, is the extraction of a root of any number, that is, it is a method for discovering what number, when raised to a certain power, will give a certain known number—e. g., the square root of 64 is 8, that is, $8^2 = 64$. Hence, if we raise 8 to the third power, will give 64; 3 is the fourth root of 81, that is, 3 raised to the fourth power is 81, and so on. The symbols expressive of the two operations are as follow: $n$ means that $n$ is to be raised to the $m$th power, or a raised power of $n$ is to be raised to the $m$th power; $\sqrt[n]{v}$ or $\sqrt[n]{a}$ signifies that the extraction of the second or square root of $v$ is required; $\sqrt[3]{256}$ or $\sqrt[2]{256}$; that the fourth root of 256 is to be extracted; and so on. Involution and evolution, like multiplication and division, or differentiation and integration, differ in the extent of their application; the former, or direct operation, can always be completed, while there are numberless cases in which the latter fail to express the result with perfect accuracy.

IODINE (synb. I, equiv. 127) is one of a group of four non-metallic elements to which the term Halogens (q. v.) has been applied. It derives its name from Gr. io̱δη, violet-like, in consequence of its magnificent purple colour when in a state of vapour. At ordinary temperatures, it usually occurs in solid dark-gray glistening scales; it is, however, crystallizable, and sometimes appears as an octahedron with a rhombohedron base. It is soft, and admits readily of trituration, has the high specific gravity of 4·95, and evolves a peculiar and disagreeable odour, which indicates its great volatility. It fuses at 255, and at about 535° it boils, and is converted into the pure liquid by fusion. It can be oxidized by a reagent, and is acid and alcohol and ether. Iodine vapour is the heaviest of all known vapours, its specific gravity being 8·716. It combines directly with phosphorus, sulphur, and the metals. Its behaviour with hydrochloric acid is analogous to that of chlorine and bromine (see HYDROCHLORIC ACID), but its affinities are weaker than those of the last-named elements. It likewise combines with numerous organic substances, and the compound which it forms with starch, although an intense blue colour, taints the solution of starch forms the best test for the presence of free iodine. By means of this test, one part of iodine may be detected when dissolved in one million parts of water.

Iodine is found in some of the most important iodine compounds. With hydrogen, it forms only one compound, hydriodic acid (HI), a colourless pungent acid gas, which in most respects is analogous with hydrochloric acid. It is obtained by the action of water on potassium or phosphorus.
IODINE—IONA.

The soluble iodides of the metals may be obtained by the direct combination of hydriodic acid with the metallic oxides, and the resulting compounds being the metallic iodide and water. Some of these iodides are of extreme brilliancy, and others are of great value in medicine; amongst the latter must be especially mentioned iodide of potassium, iodide of iron, and the iodides of mercury.

Iodide of potassium is, next to qinoline and morphia, the most important medicine in the pharmacopoeia. It crystallises in colourless cubes, which are sometimes clear, but usually have an opaque, whitish appearance, and are soluble in water and spirit. It is decomposed by the iodine act, free, by chlorine, bromine, fuming nitric acid, and ozone (q. v.). There are various ways of obtaining this salt; the folio gum is of great use. If iodine be added to a warm solution of potash until a brown tint begins to appear, iodide of potassium (KI) and iodate of potash (KO(IO3)) are formed. By gentle ignition of the residue obtained by evaporation, the iodate is decomposed into iodide of potassium, and oxygen, so that all that remains is fused iodide of potassium, which is dissolved in water, and allowed to crystallise. Iodide of iron is formed by digesting iron wire or filings in a closed vessel with four times the weight of iodine as dry. Iodine in a clear solution takes place, and a pale-green solution is formed, which by evaporation in vacuo yields crystals. It is the solution which is most commonly employed in medicine, but as, on exposure to the air, it becomes decomposed, and iodin is liberated, it is usually mixed with strong syrup, which retards this change.

There are two iodides of mercury, viz., the green sub-iodide, and the binoxide. The former has a surface of iodine in sea-water, in marine animals and plants, and in certain mineral springs. It is also found in several minerals, as, for example, in certain Mexican silver ores, in Silesian zinc ores, in phosphorite from the United States, and in the talc of Benevent. Iodide of iron was discovered in 1811, by Courtouër, in the waste liquors produced in the manufacture of carbonate of soda from the ashes of sea-weeds. A few years later, Gay-Lussac discovered that it was a simple elementary body. It is obtained from the half-fused ash of dried sea-weeds, which is known in this country as Kelp (q. v.), and in Normandy as Varek, and contains the iodides of sodium, potassium, magnesium, and perhaps calcium in considerable quantity. The iodine is liberated by the addition of binoxide of manganese and sulphuric acid. Most of our commercial iodine is prepared in Glasgow.

The preparations of iodine are employed extensively in medicine and in Photography (q. v.). Iodide of potassium, and the preparations of iodine generally, are almost entitled to be regarded as specifics in cases of goitre, bronchocele, and erysipha-ine. The preparations of this class of drugs are extremely valuable as extolants, as resolved in chronic induration, and enlargement of the liver, spleen, uterus, &c. In many forms of chronic rheumatism, and in certain affections of the osseous system, due to a syphilitic taint, iodide of potassium is of great service; and its value in the treatment of chronic lead-poisoning is not so generally known, even in the medical profession, as it deserves to be. The iodide of potassium dissolves the compounds of lead with albumen, fibrine, &c.; which abound in the body in chronic lead-poisoning; and these dissolved compounds are excreted by the kidneys. In these cases, lead may often be detected in the urine, almost immediately after the administration of the iodide. This salt has similar action in chronic mercurial poisoning, and cases are recorded of mercurial salivation having come on during the use of iodide of potassium, in consequence of the liberation of mercury, which had been previously fixed in the system.

Iodide of iron, which may be given either in syrup or in the form of Blancard's Pills (an excellent French mode of administering this salt), is especially serviceable in scrofulous affections of the glandular system, in which the use of iodine and H. U. is indicated. The iodides of mercury have been prescribed with good effect in various forms of syphilis. They must be given with caution, on account of their energy, the average dose of the red iodide being a fraction (1/40) of a grain. From those who have been prescribed internally; but in the form of tincture and ointment, it is a most useful topical application in cases of goitre, local enlargements, diseases of joints, chilblains, &c.

In large doses, iodine and most of the iodides act as irritating poisons; but very few fatal cases are on record. In the event of poisoning with the tincture of iodide, the first point is to evacuate by vomiting; and the vomiting is assisted by the copious use of tepid liquors, containing starchy matter, as, for instance, starch, flour, or arrow-root boiled in water; the object being to form iodide of starch, which is comparatively inert.

IONA, the modern name of the most famous of the Hebrides, is believed to have originated in a mistaken reading of n for u; the word, in the oldest manuscripts, being clearly written Iona. From the 6th c. to the 17th c., the island was most generally called I, H. or Hg, as, for instance, Hg, or Yi—that is, simply, 'the Island;' or Iochmmul, 1-Columb-Kille, or Hg-Colum-Kille—that is, 'the Island of Columba of the Church.'

It is about three miles long, and varies in breadth from a mile and a half to a mile and a half, and had a population of 264. Its area, computed by Bede at 'five families' (or 'five hides of land,' as the passage is rendered in the Anglo-Saxon Chronicle), is estimated at 2000 imperial acres, of which rather more than a fourth part is under tillage. The soil is naturally fruitful, and yields earlier crops than most parts of Great Britain, barley sown before the middle of June being ready for the sickle in August. This remarkable fertility was assured by miranidess of the dark ages, and, no doubt, led to the early occupation of Iona. Dun, the highest point of the island, is 330 feet above the sea-level.

Its history begins in the year 563, when St Columba (q. v.), leaving the shores of Ireland, landed upon Io, with twelve disciples. Having obtained a grant of the island, as well as from his kinsman Conall, the son of Comghall, king of the Scots, as from Brudii, the son of Menchion, king of the Picts, he built upon it a monastery, which was long regarded as the mother-church of the Picts, and was venerated not only among the Scots of Britain and Ireland, but among the Angles of the north of England, who owed their conversion to the self-same missionaries of Iona. From the end of the 6th to the

619
IONIA—IONIAN ISLANDS.

end of the 8th c., I. was scarcely second to any monastery in the British Isles; and it was this
brilliant era of its annals which rose in Jedediah
mind when he described it as 'that illustrious
island which was once the luminary of the Cole-
donian regions, whence savage clans and roving
bands brought back the best knowledge and the
blessings of religion.' But neither piety nor
learning availed to save it from the ravages of the
fierce and heathen Norsemen. They burned it in
793, and again in 802. Its 'family' (as the monks
were called) of 68 persons were martyred in 806.
A second martyrdom, in 825, is the subject of a
contemporary Latin poem by Walafridus Strabus,
abbot of the German monastery of Reichenaun,
in the Lake of Constance. On the Christmas evening
of 896, the island was again visited by the Norse-
men, who slew the abbot and 15 of his monks.
Towards the end of the next century, the monas-
tery was repaired by St Margaret, the queen of King
Malcolm Canmore. It was visited in 1015, by King
Maac, the Barefooted, St Canrey.
It was now part of that kingdom, and so fell under
the ecclesiastical jurisdiction of the Bishop of Man
and the Archbishop of Drouithem. In 1293, the bishops
of this kingdom displayed the authority of the
Maxi bishop, pulled down a monastery which he
had begun to build in the island, and placed the
abbey under the rule of an Irish abbott of Derry.
The Scottish Church had long claimed jurisdiction
in the isle; and towards the end of the 13th c., the island
fell under the rule of the Scottish king. Its
abbot was now peopled by Clnagniac monks; and
a nunnery of Austin canoheeses was planted
on its shores. Towards the end of the 15th c., it
became the see of the Scottish Bishop of the Isles,
the abbey church being his cathedral, and the
monks his chapter.

No building now remains on the island which can
claim to have sheltered St Columba or his disciples.
The ruinous church, the Lattinichan, or
Foundations, in a little bay to the west of Porta-
Churrrach; the Cobhan Cuidich, or Culdee's Cell,
in a hollow between Dumi and Dumbhriur; the
thath or hill-foin of Dumbhriur; and the Gleann-an-
Toimhneas, county of the Church, in the middle of
the island, believed to be the site of the monas-
tery which the Irish bishops destroyed in 1203. St
Oran's Chapel, now the oldest church in the island,
may perhaps be the latter part of the 11th century.
St Mary's Nunnery is perhaps a century later. The
Cathedral, or St Mary's Church, seems to have
been built chiefly in the early part of the 13th
century. It has a choir, with a sacristy on the north
side, and chapels on the south side; north and south
transcripts; a central tower, about 75 feet high; and
a nave. An inscription on one of the columns of the
choir appears to denote that it was the work of an
Irish ecclesiastic who died in 1202. On the north
of the cathedral are the chapter-house and other
remains of the conventual or monastic buildings.
In the 'Reilig Oran'—so called, it is supposed, from
St Oran, a kinsman of St Columba, the first who
found a grave in it—were buried Ecgfrid, king of
Northumbria, 864; Gedred, king of the Isles, 1188;
and Haco Ospac, king of the Isles, in 1228.
No monuments of these princes now remain. The
oldest of the many tombsfstones on the island are
two with Irish inscriptions, one of them, it is believed,
being the monument of a bishop of Conner who
died at I. in 1174.

After centuries of neglect, this interesting island
seems now to be in the way of improvement. It
possesses a beach connected with the Establishment,
also a Free Church, and a school. At present
(March 1863), a small and commodious inn is in

of erection by the Duke of Argyle, proprietor
of I.; by which means tourists and antiquarian
explorers will be enabled to see the island
within a few hours. 

IONIA; the ancient name of the most flourishing
of Asia Minor. It received its name from the
Ionians (one of the four most ancient tribes
in Greece), who, again, according to the mytho-
logical account, derived theirs from Ion, the son
of Aperus, a dagon of Aegina. According to the
usually received tradition, they were driven out of the Peloponnesus by the
Achaianis, and removed to Attica, whence, about 1050 B.C., bands of them went forth to settle on
the coast of Asia. I. was a beautiful and fertile
country, extending, according to Ptolemy, from the
river Hermus to the river Mseander, along the coast
of the Aegean Sea; but Herodotus and Strabo make
it somewhat larger. It soon reached a high point of
prosperity; agriculture and commerce flourished,
and great cities arose, of which Ephesus, Smyrna,
Clasonense, Erythra, Colophon, and Miletus were
the most celebrated. These free cities, which formed
the nucleus of the Ionian League, were, however,
gradually subdued by the kings of Darius; and
passed (557 B.C.) under the sway of the Persians,
but were allowed a considerable measure of internal
liberty. During the great Persian war, the con-
tinent which they were compelled to furnish to
their Oriental masters deserted to the Greeks, at
the battle of Mycale (479 B.C.), whereupon the Ionians
entered into an alliance with Athens, upon which
they now became dependent. After the Pelopon-
neian war, they were subject to the Spartans again
(387 B.C.) to the Persians till the time of
Alexander the Great. From this period, I. shared
the fate of the neighbouring countries, and in 64 B.C.
was added to the Roman empire by Pompey after
the third Mithridatean war. In 108 B.C., it was
so ravaged by the Turks that few traces of
its former greatness are now left.—The Ionians
were regarded as somewhat effeminate. They were
wealthy and luxurious, and the fine arts (see IONIAN
ARCHITECTURE) were cultivated at a time when
they lay decades within a much earlier date than amongst their kinsmen
in the mother-country. The Ionic Dialect
eccels the other Greek dialects in softness and smooth-
ness, chiefly from the greater number of vowels introduc-

IONIAN ISLANDS, a group, or rather chain,
running round the west coast of Epirus, and west
and south of Greece. It consists of about 40
islands, of which Corfu, Paxo, Santa Maura, Thaki,
Cephalonia, Zante, and Cervero, are of considerable
size; the total area is about 1041 square miles, and
the population (1820) 232,426, is mostly of Greek
descent. The proportion of females to males is
as 100 to 116. The collective term 'Ionian' is
of modern date. After the division of the Roman
Empire, these islands were included in the eastern
half, and so continued till 1081, when the Duke of
Calabria (subsequently king of Naples) took posses-
sion of them. From this time they underwent a
continual change of masters, till the commencement
of the 15th century, when they lay depopulated, and
the possession of the Venetians, who in 1719, ceded
them to France. They were seized by Russia and
Turkey in 1808, by France in 1807, by Britain in
1869, and by Austria in 1869. They were per-
formed into a republic ('The Septinsular Republic') under the pres-
torate of the latter. The following is a sketch

I.
of their present political condition. The government is carried on by two assemblies, and the Lord High Commissioner, who is the representative of Her Majesty. The lower assembly consists of 40 members, who must be nobles; 29 of them are elected by the islanders themselves, and 11 by the Lord High Commissioner, the term of office is 4 years, during which period they must hold three sessions, of three months each. The Senate, composed of five members, which the commission has power to increase to seven, forms the executive. The commissioner is invested with extensive powers: he can convolve an extraordinary meeting of parliament, confirm or reject the resolutions of the Senate, and veto all bills passed by the legislature. He has the nomination of most of the public functionaries, and has supreme jurisdiction in all matters of finance, police, and public safety. Up to 1848, the press was restricted, and the government was really a despotism; but since that time they have obtained liberty of the press, lowering of the franchise, perfect freedom of election, both parliamentary and municipal, and vote by ballot. Justice is administered by a supreme court; and a civil, criminal, and commercial tribunal in each of the seven principal islands. The principal mode of action in any prosecution is on Corfu, four native regiments of militia, and two war-vessels. In 1860, the islands produced 69,553 barrels of olive-oil, 30,250,897 lbs. of currants, and 148,529 barrels of wine; and of wheat, only 67,580 bushels; the value considerably exceeding £500,000. The live-stock for the same year consisted of 13,171 horses, 10,374 cattle, 131,684 sheep, and 111,907 goats, a considerable increase on the previous years. The revenue (1860) was £140,855, and the expenditure (which generally exceeds the income), £151,187. The chief item in the revenue is the export-duty on olives and olive-oil. The Board of Trade Reports lately published (1862) give, for 1859, the imports at £1,536,953, and the exports at 2,529,057. The entrances and clearances of shipping for 1860 were respectively 517,320 and 325,802 tons. The I. L. have cost Britain, on an average, £100,000 per annum.

Notwithstanding the advantages enjoyed under British government, there is a widespread dislike to British, and especially since 1853, the mass of the people have clamoured for annexation to Greece. Recently, however, it has been proposed to resign the protectorate of the I. L. and to permit annexation to Greece.

IONIAN MODE, in Music, one of the old church modes, said to be the same as the ancient Greek mode of that name, and the only one of the old church modes which agrees with our modern system of music, the Ionian mode being the same as our key of C. major. The character of the Ionian mode, however, must have appeared to the ancients more properly defined than it can to us, as it was the only one of their modes which had a major third and a sharp seventh.

IONIC ARCHITECTURE, a style of Greek architecture which took its origin in Ionia, and seems to have derived many of its characteristic features from Assyria. See GRECIAN ARCHITECTURE. The chief peculiarity of Ionic architecture is the capital of the Columns (q. v.), which is decorated with spiral ornaments called Volutes (q. v.). The columns have also bases, which were not used in Doric architecture. The cornice is distinguished by the dentil border. An Doric column introduced in this style. The Honeysuckle ornament (q. v.), so much used in Ionic architecture, is one of the features which indicate its eastern origin.

Many large temples were erected in this style in Asia Minor and Greece. Among the finest examples now existing are the temples of Erechtheus and Minerva Polias on the Acropolis at Athens, Apollo Didymeus at Miletus, Minerva Polias at Priene, and Bacchus at Teos; and the temple of Fortune at Athens.

IONIC SCHOOL is the collective name given to the earliest Greek philosophers, Thales, Anaximander, Anaximenes, Heracleitus, and Anaxagoras, on account of their following one general tendency, and belonging for the most part to Ionia. See the biographies of these philosophers.

I. O. U., a memorandum of debt given by a borrower to a lender, so called from being made in this abbreviated form:

LONDON, January 1, 1867.

Mr A. B. I. O. U. £200.

C. D.

It is a convenient document, because it requires no stamp, and yet it is valuable evidence of the existence of the debt, in case an action is afterwards brought. If, however, the I. O. U. contain any description of the property given as security, it will be held to a promissory-note, and be void unless it have a stamp.

IOWA, one of the United States of America, was organised as a state, with governor and legislature, in 1848. It lies between 40° 29' and 45° 30' N. lat., and 90° 12' and 94° 27' W. long., and extends 369 miles from north to south, and 300 from east to west, with an area of 50,914 square miles, or 32,584,960 acres. It is bounded on the N. by Minnesota; E. by Wisconsin and Illinois, from which it is separated by the Mississippi River; S. by Missouri; and W. by Nebraska Territory, from which it is separated by the Missouri River. It has 99 counties, with Des Moines, a central town, for its capital. The population in 1860 was 49,112; in 1850, 192,214; in 1840, 674,948. The rivers are the Mississippi and Missouri on its eastern and western borders, and the Des Moines, Iowa, Red Cedar, and their branches. The surface is undulating, and is most beautiful, with alternate forests and prairies. There are no mountains; but bold bluffs, with picturesque ravines, line the rivers. In the north-east, there are rich deposits of lead, and coal in the south and west, with iron, marble, clay, gypsum, &c. The soil is exceedingly fertile, and the climate healthful; the peach blossoms in the middle of April, but the winters are severe, with an average of 26°. The chief productions are wheat, maize, flax, tobacco, cattle, and hogs. It has not much direct foreign commerce, but trades extensively with the Atlantic and Gulf towns, and with the interior. The chief river ports of I. are Keokuk, Fort Madison, Burlington, Muscatine, Davenport, Clinton, Bellevue, and Dubuque. There are many manufactories, and 13 railways built or in progress, mostly crossing the state from east to west. There are 28 colleges, and 2700 public schools.

IOWA CITY, a city in Iowa, United States of America, formerly the capital of the territorial government, is situated on the Iowa River, 80 miles from its mouth. It is built on a succession of plateaus, rising from the river. The first is a public promenade; the third is crowned by the capitol, now the state university. It has also county buildings, and the state asylums, with factories on the river, and hospitals. The river then becomes a boat navigation to the Mississippi, and connection with the east by railway. Pop. in 1850, 2262; in 1860, 2214.
IPECAUCANHA—IPSWICH.

IPECAUCANHA, the same both of a very valuable medicine and of the plant producing it. The plant (Cephalis ipecacuanha) belongs to the natural order Cichonacea, and grows in damp shaly soils in Brazil and some other parts of South America. It is somewhat shrubly, with a few oblong-lanceolate leaves near the ends of the branches, long-stalked heads of small white flowers, and soft dark purple berries. The part of L. used in medicine is the root, which is simple or divided into a few branches, flexuous, about as thick as a goosequill, and is composed of rings of various size, somewhat fleshy when fresh, and appearing as if closely action or so much nausea and depression as tartar emetic.

I. is useful as an emetic when it is necessary to unload the stomach in cases where there is great debility, or in childhood. As a nauseant, expectorant, and diaphoretic, it is prescribed in affections of the respiratory organs, as croup, hooping-cough, asthma, &c.; in affections of the alimentary canal, as indigestion, dysentery, &c.; and in disorders in which it is desired to increase the action of the skin, as in diabetes, febrile affections, &c.

Besides the Powder, the most useful preparations are the Wine of L.—of which the dose to an adult as a diaphoretic and expectorant ranges from 10 to 40 minims, and as an emetic from 2 to 4 draughts—and the Compound L. Powder, commonly known as Dover's Powder (q.v.). To produce the full effect as a sudorific, a dose of ten grains of Dover's Powder should be followed by copious draughts of white-wine whey, treacle-posset, or some other warm and harmless drink.

IPHIGENIA, in Grecian legend, a daughter of Agamemnon and Clytemnestra, or, according to others, an adopted daughter of Clytemnestra. Her father, having offended Diana, vowed to make atonement by sacrificing to the goddess the most beautiful thing born within the year. This happened to be Iphigenia. Agamemnon long delayed the fulfilment of his vow, but at length the Trojan expedition drew on, and the Greek fleet being detained in Aulis by a calm, the seer Calchas declared that Agamemnon must keep his promise. When L. was brought to the altar, however, she disappeared, and a hind lay there in her stead, Diana herself having carried her off in a cloud to Tauris, where she became her priestess, but was afterwards recognised by her brother, Orestes, who carried her, along with the image of Diana, to Attica. The legend is of post-Homeric origin. It has, however, been much wrought into Grecian poetry, and afforded many subjects to painters and sculptors. In modern literature, it has been again employed with great power of genius and poetic art by Goethe in his Iphigenia auf Tauris.

IPOMEA, a genus of plants of the natural order Convolvulacea, differing very little from the genus Convolulus. The species are numerous. They are mostly either annual or warm countries are often to be seen in flower-gardens and hot-houses, being very ornamental, and readily covering trellises with their twining stems, large leaves, and large beautiful flowers. The roots of some of them yield a resinous substance, which possesses properties resembling those of jalap, and the true Jalap (q.v.) plant itself has sometimes been referred to this genus.

IPSAMBUL. See ABROSMAMUL.

IPSICA. See MODICA.

IPSWICH, a market-town, parliamentary and municipal borough, and river-port of England, capital of the county of Suffolk, is agreeably situated on the river Orwell, at the foot of a range of hills, 68 miles north-east of London. The older portions of the town consist of narrow and irregular streets, some of the old houses of which are ornamented with curious carved work. It contains numerous churches, and benevolent and charitable institutions; a Mechanics' Institution, with about 700 members; and a Working Men's College, with 200 members. Of its educational establishments, the principal is the grammar school, founded by Carthusian Wolsey, and endowed by Queen Elizabeth. It has an income from endowment of £116, 6s. 8d., has six scholarships, exclusive of an Albert scholarship,
founded as a memorial of the late Prince Consort, and two exhibitions at Pembroke College, Cambridge. There are large iron and soap factories, breweries, corn-mills, and ship-building docks. In 1861, 2,250 vessels, of 162,467 tons, entered and cleared the port; they carried chiefly agricultural produce, and agricultural implements and machinery; imports, wine, coal, iron, and timber. The town can be approached by vessels of 500 tons. It sends two members to the imperial parliament. For 1875 (37,648) the chief wares were pig-iron and dismantled by the Dunes in 991, and again in 1000.

IRA-K-AJEMI, a large province of Persia, is bounded on the N. by the provinces of Azerbaijan, Gilan, and Mazanderan, and on the E. by Khorasan. On the S. and W., the boundaries are not definitely laid down. In the extreme north are the Elburz Mountains, and throughout the province there are several other chains, all of them running from south-east to north-west. A great portion of the surface of the province consists of elevated tablelands, but there are also numerous fertile valleys traversed by rivers. Most of the rivers I. are swallowed up by sandy tracts into which they flow. The chief towns of the province are the capital Teheran and Isphahan.

IRA-K-ARABI, a district in Turkey in Asia, the ancient Babylonia (q. v.), comprises the ruins of the ancient cities of Babylon, Sardis, and Ctesiphon. During the last 250 years of the caliphate, this was the poor remnant of their once wide dominion which remained to the successors of Mohammed.

IRA N, the modern native name of Persia. See AVAN RACE.

IRET, a district town of the government of Perm, Eastern Russia, since 1775; founded (1863) by Russian emigrants. The town is situated on the rivers Irbit and Nitza, in lat. 57° 35' N., and long. 62° 50' E., is 1760 miles distant from St. Petersburg, and contains 32,484 inhabitants. It is remarkable for its extensive fair, the largest in Russia, after that of Nijni-Novgorod. The fair takes place annually from the 27th of February till the end of March, has been instituted for more than 200 years, and attracts about 10,000 merchants and visitors from Russia, Siberia, Persia, Bokhara, &c. The principal goods are cloth, silk stuffs, brocades, sugar, coffee, china, and hardware from Russia; tea and unkeen from China, through Kutchta; furs and fish from Siberia; cotton stuffs from Bokhara, &c. The whole quantity of goods brought to market is valued at £5,500,000, of which more than three-quarters are generally disposed of.

IRELAND, an island, forming part of the United Kingdom of great Britain and Ireland, lies between lat. 51° 26' and 55° 23' N., and long. 4° 20' and 10° 26' W. It is washed on the N., W., and S. by the Atlantic, and on the E. by a strait, called at different places the North Channel, the Irish Sea, and St. George's Channel, which separates it from the larger island of Great Britain. Its greatest length, from Fair Head in Antrim to Croy Head in Kerry, is 306 miles, but its greatest meridional length is not more than 225; its greatest breadth, between the mainland and the island off the west coast, is 189 miles, but between Galway Bay and Dublin, it is not more than 120. Area about 32,510 square miles. Pop. (1861) 5,764,543. I. is divided into the four provinces of Ulster, Leinster, Munster, and Connacht which again are subdivided into 32 counties. The following table exhibits some important statistics:

IRA K-AJEMI—IRELAND.
IRELAND.

A large portion of Kildare, Carlow, King’s and Queen’s counties—having a summit elevation of 280 feet. Extensive tracts of deep wet bog also occur in Longford, Roscommon, and other counties, and give a peculiar dreary and desolate aspect to the scenery. Notwithstanding the quantity of water in those bogs, they exude no miasmatic injurious to health, owing to the large quantity of tannin which they contain.

Hydrography.—The principal river of I., and the largest in the United Kingdom, is the Shannon (q. v.). The streams which drain the eastern part of the central plain are the Liffey and the Boyne; the south-eastern part, the Bann, the Barrow, and the Nore; while the waters of the north-eastern part are collected into Lough Neagh, chiefly by the Blackwater, and thence discharged into the sea by the Lower Bann. The rivers external to the great central plain are necessarily short. The principal are the Erne, flowing to the north-west; the Foyle and the Bann, to the north; the Lagan, to the north-east; the Slaney, to the south-east; and the Bandon, Lee, and Blackwater, flowing in an easterly direction through the central part of Cork, the most southern county in the island. None of these rivers are naturally of importance to navigation. The Shannon, however, has been made navigable to a considerable extent by means of locks and lateral cuts; the Barrow, by similar means, to Athy; the Foyle, by canal to Strabane; and several of the others have been artificially united by such lines as the Lagan, Newry, Usher, Royal, Gran, Athy, and other canals, which now intersect a considerable portion of the island.

The lakes of I. (called loughs) are, as might be expected from the surface-character of the country, both numerous and extensive in proportion to the size of the country. The largest is Lough Neagh, and in Ulster, covering an area of 100,000 acres. The other loughs of consequence are Loughs Erne and Derg, also in Ulster; Cun, Mask, and Corrib, in Connacht; the Allen, Ree, and Derg, which are expansions of the river Shannon, and the lakes of Killarney (q. v.) in Kerry. The bays and salt-water loughs which indent the island are also numerous and of considerable importance. About seventy are suitable for the ordinary purposes of commerce; and there are fourteen in which the largest men-of-war may ride in safety. The principal are Loughs Foyle and Swilly, on the north coast; the Bays of Donegal, Sligo, Clew, and Galway, the estuary of the Shannon, Dingle, Bantry, and Baltimore Bay, on the west; the harbours of Cork and Waterford, on the south; Wexford harbour, the Bays of Dublin, Drogheda, and Dundalk, and Loughs Carlingford, Strangford, and Belfast, on the east.

—The islands are, generally speaking, small and of little importance. On the east coast, the largest is Lambay, about two and a half miles off the coast of Dublin; on the south and south-east coasts are Clear Island, the Saltees, a dangerous group of islets, about eight miles south of the Wexford coast, indicated by a floating light, and Tuscarr Rock, about eight miles east of Carnsore Point, also a dangerous ledge, rising 20 feet above the sea, and surmounted by a lighthouse after the model of the Eddystone; on the west coast, the Skelligs, Valentia, the Blaskets, the South Arran Islets, Innisbofin, Innisturk, and Clare, Achill or ‘Eagle’ Island, and the Inishkea Islets; on the north coast, the North Arran Isles, the Tory Isles, and Inishbofin.

Geology.—A great series of grits and slates of Cambrian age occur in the south-east of I.; the upper portion contains a few fossils of zoophytes and worms. Lower Silurian strata rest unconformably on the Cambrian rocks in the same district. They consist of flags, slates, and grits many thousand feet in thickness, extending over large portions of Kildare, Wicklow, Waterford, and Waterford. Several detached patches occur to the west of this district, forming the Keeper, Arra, and Inchiquin Mountains. A tract of similar beds stretches from the centre of I., near the source of the Shannon, to the coast of Down. The strata in proximity to the Wicklow Mountains are converted into beds of sand and mica-slate. This is the condition of all the beds in the north-west, in Donegal, Tyrone, and Mayo; they appear to be a continuation of the highly altered strata of the north of Scotland. Detached portions are found in the counties of Carlow, Laois, Offaly, and other eastern and north-eastern counties. The rocks are of a similar nature; these are identified as the Silurian rocks of Waterford and Cork. Along the bases of the Silurian mountains of the south centre of I., and in the southern portion of the county of Cork, occurs a period of the Silurian system of geologists, which has yielded no fossils; some geologists refer these to the Old Red series, others hold them to be Lower Carboniferous.

The Carboniferous Limestone is extensively developed over the greater part of the centre of the country, except in those places already alluded to, where the older rocks appear on the surface. This great tract is an extensive plain covered with drift, and with peat-moss and freshwater marl, in which are seen the remains of the Silurian rocks of Rosslare and Bos longipennis. In Kerry, Cork, and Waterford, the strata are very much contorted, the coal-seams are changed into anthracite, and so squeezed and crushed as to be got only in small dice-like fragments. Further north, the strata are nearly horizontal, but the coal-fields are limited, and the seams are generally of considerable thickness. They occur chiefly in Tipperary, Kilkenny, Tyrone, and Antrim. The strata in Ardglass and Ards of County Down, and in Arderea in Tyrone, and at Cútira near Belfast; the sandstones of Roan Hill near Dungannon are probably of the same age. The red and variegated marls containing beds of gypsum and rock-salt, which occur in the county of Down, are probably Triassic. Resting on these marls are a few thin beds of Lias. Cretaceous strata occur in Antrim and Derry.

Climate.—Though the climate of I. bears, as might have been expected, a strong resemblance to that of Great Britain (q. v.), it has yet a character peculiar to itself, owing to the marked difference in the configuration of its surface, its greater distance from the continent of Europe, and its being, as it were, more completely bathed in the warm waters of the Gulf Stream. The mean annual temperature of the central parts of the country is about 50°, rising in the south to 51°5, and falling in the north to 48°5. There are thus 3° of difference between the extreme north and south, and it may be noted that, speaking generally, this difference is constant through all the seasons of the year. The mean temperature in winter is 41°5; in spring, 47°; in summer, 60°; and in autumn, 51°.

The annual rainfall averages from 25 to 28 inches, except in the neighbourhood of hills, where the precipitation is considerably augmented; thus, at Valentia, in Kerry, the rainfall of 1861 amounted to 73 inches, and doubtless this large fall was
IRELAND.

greatly exceeded in those parts which are situated among the higher hills. The rainfall in winter, particularly in the west, is greatly in excess of the ordinary quantity of rain falling to the low temperature of the surface of the ground during winter, which suddenly chills the warm and moist south-west winds that prevail, especially at this time of the year, and condenses their vapour into rain. Since in Great Britain the chief maritime range of the mainland is east, it follows that over the whole eastern slope of the island the climate is drier, the amount and frequency of the rainfall much less, and the sunshine much more brilliant than in the west. In L. on the other hand, the hills in the west do not possess such a continuous barrier to the onward progress of the south-west winds, but are more broken up and distributed in isolated groups. It follows that the sky is more clouded, and rain falls more frequently in L., and the climate is thus rendered more genial and fostering to vegetation; hence the appropriateness of the name 'Emerald Isle.' Again, owing to its greater distance from the continent, the parching and anxious east winds of spring are less severely felt in L., because the north-east winds have acquired more warmth and moisture in their progress. It is on this account that the most salubrious spring climates possessed by England, Scotland, and I. are situated in the south-west of the island and not in the countries. Thus Queenstown, in the south-west of I., enjoys an average spring temperature as high as 50°, which is about the highest in the British Islands, and nearly 3° higher than the east of Kent, which is nearly in the same latitude. Since wheat ripens in these latitudes with a mean summer temperature of 50°, it follows that the climate of I. is quite sufficient for the successful cultivation of the finer sorts of grain, which are subject combinations, with the fertility of the soil, open up for I., as far as the physical conditions are concerned, a prospect of great national prosperity, based on most remarkable, though as yet only partially developed agricultural resources.

The estimated produce per statute acre in 1860 and 1861 was as under:

**Live-stock.** According to the census returns of 1841, the estimated value of the live-stock was £24,399,843; for 1851, £27,737,393; and for 1861, £32,760,033.

**Fisheries.**—In her fisheries, I. possesses an almost inexhaustible mine of wealth, but, strange to say, it is almost entirely neglected. The surrounding seas swarm with ool, ling, hake, herrings, pilchards, &c., and yet the fish markets are extensively supplied with cured fish from Scotland and the Isle of Man. The number of boats engaged in the sea-fisheries in 1855 was 12,500, employing 49,754 men and boys, and these numbers are on the decrease, owing, it is said, to the continuous emigration from the seaport towns, and the great demand for seamen.

**Manufactures.**—According to McCulloch, 'Ireland is not, and never has been, a manufacturing country. Its unsettled turbulent state, and the general dependence of the population on land, have hitherto formed insuperable obstacles to the formation of great manufacturing establishments in most parts of the country; whilst the want of coal, capital, and skilful workmen, and the great ascendency of England and Scotland in all departments of manufacture, will,

there is reason to think, hinder Ireland from ever attaining eminence in this department.' Linen is the staple manufacture, of which Belfast and the surrounding districts of Ulster are the chief seats. The staple manufacture, of which Belfast and the surrounding districts of Ulster are the chief seats. The annual value of the linen now exported from I. to Great Britain and all foreign countries reaches about £4,400,000. The manufacture of woollen stuffs is generally confined to the counties of Down, Queen's, and Antrim, and the south-eastern parts of I. The manufacture of flax, jute, and silk is in I., amounting to 158, employing 739,305 spindles, 6600 power-looms, and 37,872 persons of both sexes; of these, 140 were flax-factories, employing 392,981 spindles, 4666 power-looms, and 33,225 persons of both sexes. A great source of employment for females has of late years sprung up in the north of I., in the working of patterns on mullin with the needle. Belfast is the centre of this manufacture, which employs about 500,000 persons, chiefly females, scattered through all the counties of Ulster, and some localities of the other provinces. About forty firms are engaged in the trade, and the gross value of the manufactured goods amounts to about £1,400,000.

**Commerces and Shipping.**—The exportation of the agricultural produce of the country has always been the chief commercial business carried on in Ireland. By far the greater part of this trade is carried on with Great Britain. It cannot, however, be traced later than 1825, when the commercial intercourse between Great Britain and I. was assimilated by law to the coasting-traffic carried on between the different ports of England, except in the single article of grain.

The number and tonnage of vessels entered and
IRELAND.

Cleared out at the 19 principal Irish ports, in the Coasting, Colonial, and Foreign Traders in 1861, were as follows: vessels, 44,490; tonnage, 7,141,538.

Government.—The government of I., since the Union in 1801, is identical with that of Great Britain. It is represented in the imperial parliament by 32 members of the House of Lords, and 105 of the House of Commons. The executive government is invested in a Lord-lieutenant, assisted by a Privy Council and Chief Secretary; and the law is administered by a Lord Chancellor, a Master of the Rolls, and twelve pairs of courts of law, each province of I. appears to have had its own king, subject to the Arl-Righ or monarch, to whom the central dis- trict called Meath was allotted, and who usually resided at Tara. Each clan was governed by a chief selected from its most important families, who was required to be of mature age, capable of taking the field efficiently when occasion required. The laws were peculiar in their nature, dispensed by professional jurists styled Brehons, who, as well as all other poets and men of learning, received high consideration, and were endowed with lands and important privileges. Cromlechs, or stone tombs and structures, composed of large uncut stones, such as the pagan Irians set up in various parts of Ireland. Lacustrine habitations or stockaded islands, styled Carnanys or Cranogas (q. v.), in inland lakes, also appear to have been in use there from early ages. Of articles of metal, stone, clay, and other materials in use among the ancient Irish, a large collection has been formed in the Museum of the Royal Irish Academy at Dublin. It is remarkable that a greater number and variety of antique golden articles of remote antiquity are found in Ireland than any other part of Northern Europe; and the majority of the gold antiquities illustrative of British history, now preserved in the British Museum, are Irish.

In the 6th c., extensive monasteries were founded in I., called religious most important parts which was required to be of mature age, capable of taking the field efficiently when occasion required. The laws were peculiar in their nature, dispensed by professional jurists styled Brehons, who, as well as all other poets and men of learning, received high consideration, and were endowed with lands and important privileges. It is remarkable that a greater number and variety of antique golden articles of remote antiquity are found in Ireland than any other part of Northern Europe; and the majority of the gold antiquities illustrative of British history, now preserved in the British Museum, are Irish.

Taking the pupils of 1861, we find the number of Roman Catholic children to be 486,206; of Presby- terian, 64,887; of Episcopal, 34,717; belonging to other sects, 3,402. Besides these national schools, the 'Church Education Society' had (1855) 1,827 schools, attended by 90,572 pupils, of whom 17,000 were Roman Catholics.

History.—According to ancient native legends, I. was in remote times peopled by tribes styled Fir-bolgs and Danuans, eventually subdued by Milesians or Gauls, who acquired supremacy in the island. The primitive inhabitants of I. are now believed to have been of the same Indo-European race with the original population of Britain. Although I., styled Iervis, is mentioned in a Greek poem five centuries before Christ, and by the names of Hibernia and Ír, mentioned under the Roman invasion, I. is known with certainty of her inhabitants before the 4th c. after Christ, when, under the appellation of Scoti, or inhabitants of Scotia, they became formidable by their descents upon the Roman province of Britain. These expeditions were con- tinued and extended to the coasts of Gaul till the time of Laogaire MacNeill, monarch of Ireland (43 A.D.), in whose reign St. Patrick (q. v.) attempted the conversion of the natives. Although Christian- ity was not originally introduced into the island, Patrick encountered great obstacles, and the new faith was not fully established in I. till about a century after his death. From the earliest period, each province of I. appears to have had its own king, subject to the Arl-Righ or monarch, to whom the central dis- trict called Meath was allotted, and who usually resided at Tara. Each clan was governed by a chief selected from its most important families, who was required to be of mature age, capable of taking the field efficiently when occasion required. IRELAND.

close of the 8th to the 12th c., L. although harrassed by the Scandinavians, produced many writers of merit, among whom we...Egna, the hagiographer; Cormac MacCullen, king of Munster, and Bishop of Cashel, the reputed author of Cormac's Glossary; Cuan O'Lochlain; Gilla Modesta; Flan of Monster-

bome; and Tigernach, the annalist. The Irish scholars who during these times acquired highest eminence on the continent were Joannes Erigena, the favourite of Charles the Bald of France; Dungal, one of the last to bear the title of King; floods; and Dehuiull, the geographer; Donogh, or Donatus, Bishop of Fiesole; and Marianus Scotus. Of the state of the arts in Ireland during the same period, elaborate specimens survive in the shrine of St. Patrick's bell, the Cross of Cong, in Mayo (12th c.); the Limerick and Cashel crosses, and the Tara brooch, all displaying minute skill and peculiar style. To these times some are inclined to assign the Book of Kells, a Latin copy of the four Gospels in the Irish character, in the library of Trinity College, Dublin, which Mr. Westwood has pronounced to be the most elaborately executed manuscript of early art now in existence, and of portions of which fac-similes are given in his work. Poems and Psalters were common, and the architecture of the period, examples survive at Cashel. The well-known round towers of L. are believed to have been erected about this era as bell-towers, and to serve as places of security for ecclesiastics during disturbances. The skill of the Irish musicians in the 12th c. is attested by the enthusiastic encomiums bestowed by Girdaldus Cambrensis upon their performances. The Scandi-
navians lent them left behind them, no traces of their civilisation except coins struck at Dublin, Water-
ford, and Limerick, in which towns they were, for the most part, subject and tributary to the natives.

The first step towards an Anglo-Norman descent upon L. was made by Henry II., who obtained in 1155 a bull from Pope Adrian IV., authorising him to take possession of the island, on condition of paying to the papal treasury a stipulated annual revenue. Political circumstances prevented Henry from making a landing in L. in 1166, when Dermot MacMurrough, the deposed king of Leinster, repaired to him, and obtained authority to enlist such of his subjects as might be inclined to aid him in attempting to regain the forfeited lands. Dermot, returning to L. in 1169, with the aid of his foreign mercenaries, and still more numerous Irish allies, succeeded in recovering part of his former territories, and in capturing Dublin and other towns on the eastern coast. After his death in 1171, the succession to the king-
dom of Leinster was claimed by his son-in-law, Richard FitzGislebert, Earl of Pembroke, assumed Strongbow. In the following year, King Henry, with a formidable armament, visited L., received homage from several of the minor native chiefs, and from the chief adventurers, granting to the latter charters authorising them, as his subjects, to take possession of the entire island, in virtue of the visitation. These Anglo-Norman adventurers, FitzGislebert, Le Gros, De Cogan, De Lacy, and De Curci, encountered formidable opposition before they succeeded in establishing themselves on the lands which they thus claimed. The government was committed to a viceroy, and the Norman legal system was introduced into such parts of the island as were reduced to obedience to England. The youthful Prince John was sent by King Henry into L. in 1184; but the injudicious conduct of his council having excited disturbances, he was soon recalled to England. John, when king, made an expedition into L. in 1210, to curb the refractory spirit in his barons, who had become formidable through their alliances with the natives. During the 13th c., the principal Anglo-Norman adventurers suc-
ceded in establishing themselves, with the feudal institutions of their nation, in some parts of L., by the assistance or suppression of native clans. The Fitzgeralds, or Geraldines, acquired almost unbounded power in Kildare and East Munster, or Desmond; the Lo Bottlers, or Butlers, in Ormond; or W. Munster, or Cork; and the Burkes, in Connought. After the battle of Blessinckburn, the native Irish of the north invited over Edward Bruce, and attempted to overthrow the English power in Ireland. The court of Rome, at the instance of England, excommunicated Bruce with his Irish allies; but although his enter-
prise failed of success, the general result was a comparative collapse of the English dominion in Ireland. The descendants of the most powerful settlers gradually became identified with the natives, whose language, habits, and laws they adopted to so great an extent, that the Anglo-Irish parliament passed, in 1367, the 'Statute of Kilkenny,' decreeing excommunication and heavy penalties against all those who followed not in custom of the nation, or took upon themselves with, the native Irish. This statute, how-
ever, remained inoperative; and although Richard II., later in the 14th c., made expeditions into L. with large forces, to effect a practical result; and the power and influence of the nation increased so much, that the authority of the English crown became limited to a few towns on the coast, and the district termed 'the Pale,' comprising a small circuit about Dublin and Drogheda.

In 1354, Thomas Fitzgerald, son of the viceroy of Henry VIII., revolted, but not meeting with ade-
quate support from his Anglo-Irish connections, he was, after a short time, suppressed and executed. Henry received the title of 'king of Ireland' in 1541, by an act passed by the Anglo-Irish parlia-
mament in Dublin; and about the same period, some of the native princes were induced to acknowledge him as their sovereign, and to accept peerages. The doctrines of the Reformation met with a favour in L. with the descendants of the old English settlers or with the native Irish. Among the middle of the 16th c., Shane O'Neill, a prince of the most powerful of Ulster, attempted to extend his power over his rivals, and to assume the kingship of that province, in which he was eventually unsuccessful; but after his death in 1567, his successor received the title of Earl of Tirone from Elizabeth. The attempts of the English government in L. to introduce the Reformed faith and English institutions stirred up great dis-
sensions in Ireland. Among the first to revolt was the Earl of Desmond, after whose death, in 1583, his vast estates in Munster were parcelled out to English settlers. Soon after, the chief clans of Ulster took up arms; and in opposing them, the forces of Elizabeth, commanded by officers of high military reputation, encountered many reverses, the most severe of which was that in 1598 at the battle of the Yellow Ford, where the Anglo-

English army was routed and its general, Philip III. of Spain, at the solicitation of the Irish chiefs, despatched a body of troops to their assist-

ance in 1601, which, landing in the Shannon, instead of in the north, as had been expected, were unable to effect anything, and were constrained to surrender. Although Elizabeth was supported by numbers of native Irish, the northern chiefs, O'Neill and O'Donnell, held out till the queen's government came to terms with them in 1603, recognising them as Earls of Tirone and Tirconnell. In 1608, these noblemen, having apprehensions for their personal...
safety, quitted Ireland unexpectedly, and retired to the continent. Their withdrawal enabled James I. to carry out that project of parcelling out the north of Ireland to Scottish and English settlers, which is thus known as the 'Platation of Ulster.' 

The Irish took advantage of the contentions in England to rise in insurrection (1641) and massacre the Protestants. It is believed that nearly 40,000 fell on both sides. The country continued in a state of anarchy till 1649, when Cromwell overran it. At the Revolution, the native Irish generally took the part of James II., the English and Scotch 'colonists' of William and Mary; and the war was kept up for four years (1688-1692). From this time till 1778, history records little beyond the passing of penal statutes against the Roman Catholics. In 1778, parliament relaxed the stringent pressure of these acts; but the widely spread dissatisfaction which they caused gave birth to numerous societies, resulting in the rebellion of 1798, which was not suppressed till 1800. On January 1 of the following year, the legislative union of Great Britain with Ireland was consummated, and from this period the history of the country merges in that of Great Britain.

IRELAND, ARMS OF. The insignia of Ireland have been variously given by early writers. In the reign of Edward IV., a commission appointed to inquire what were the arms of I., found them to be three crowns in pale. It has been supposed that these crowns were abandoned at the Reformation, from an idea that they might denote the feudal sovereignty of the pope, whose vassal the king of England was, as lord of Ireland. However, in a MS. in the Heralds' College of the time of Henry VII., the arms of I. are blazoned azure, a harp or, stringed argent; and when they were for the first time placed on the royal shield on the accession of James I., they were thus delineated: the crest is on a wreath and azure, a tower (sometimes triple-towered) or, from the port, a harp springing argent. Another crest is a harp or. The national flag of I. exhibits the harp in a field vert. The royal badge of I., as settled by statute in 1801, is a harp or, stringed argent and a trefoil vert, both ensignished with the imperial crown.

IRELAND, NEW. See NEW IRELAND.

IRELAND ISLAND, one of the Bermudas (q.v.).

IRENÆUS, one of the most important of the ante-Nicene Christian writers, was an Asiatic by birth, but is known in history solely through his connection with the Greco-Gaulish church of Southern France, of which he was a bishop. He was a scholar of Polycarp, through whom he may be regarded as having sat at the feet of St John the apostle and evangelist. I. was a priest of the church of Lyon under the Bishop Pothinus, upon whose martyrdom, in the persecution of Marcus Aurelius in 177, he was himself elected to the same see, which he continued to govern for twenty-five years. I. is commonly believed to have suffered martyrdom at Lyon in the persecution under Septimius Severus in 202. His principal, indeed almost his only work, is that which is commonly cited as A.D. 205: Against Heresies. It is directed against the Gnosticism of his own age, and is most valuable as a picture of the doctrinal and moral condition of that age. Most of his chief errors were doctrinal; but they are known only by description or by fragmenta. The earliest edition of the works of this Father is that of Erasmus (Basel, 1526). They have been several times re-edited, the most prized edition being that of the Benedictine, Dom Massuet (Paris, 1710, and Venice, 1734).

IRENE, a celebrated Byzantine empress, was born in Athens about 792 A.D. Her beauty and talent excited the admiration of the Emperor Leo IV., who married her, 799 A.D. She is said to have been the mother of Michael IV., 800 A.D., after which event she became regent during the minority of her son, Constantine VII., then only nine years of age. A great worshipper of images—in fact, this species of idolatry during the lifetime of her husband caused her to be banished from the imperial palace—she quickly began to plot for their restoration, and with this purpose assembled a council of bishops at Constantinople, 786 A.D., which, however, was successful, and image-worship was re-established in the Eastern Church. In 788 A.D., her army was defeated in Calabria by Charlemagne, who threatened the revenues of the empire. In 790 A.D., Constantine succeeded in taking the government out of her hands; but seven years after, she caused him to be deprived of his eyes, and shut up in a dungeon, where he soon died. Still she was not free from anxiety, for she had two favourites, Stauracius and Zenon, who were constantly embroiled with each other, and their jealousies only ceased with the death of the former, 800 A.D. She now tried to secure her possession of the throne by a marriage with Charlemagne, but the Frank emperor had apparently no relish for a woman who had committed so many crimes, and the scheme proved abortive. Two years later, her treasurer, Nephonius, rebelled against her, and suddenly seizing her person, banished her to the island of Lesbos, where she was forced to spin for a livelihood. Here she died of grief, 803 A.D. I. was a wise, able, and energetic ruler; but her crimes were so great and unnatural, that history can speak of her character as a whole only in the language of reprobation. The Greek Church, however, on account of her zeal for image-worship, has placed her in the catalogue of its saints.

IRIARTEA, a genus of palms, all South American, having lofty, smooth, faintly ringed stems, and pinnate leaves with somewhat triangular leaflets. The leaf-base rise from a sheathing column. The PASHIURA or PIZIURA PALM (I. exorrhiza), common in swamps and marshy grounds in the forests of the Amazon district, is remarkable for sending out roots above ground, which extend obliquely downwards, and often divide into many rootlets just before they reach the soil; the plant as it grows still producing new roots from a higher point than before, whilst the older and more central ones die, so that at last a lofty tree is supported as on three or four legs, between which a man may walk erect with a palm. I. exorrhiza has roots, high rising straight above his head. The outer wood is very hard, so as to be used for harpoons; splits easily, and into perfectly straight laths; is excellent for foces.
